Another lady, from Springfield, Mass., aged twenty-eight, had been unable to use her right leg for twenty-six years; she had upon her limb irons, as in the other case. The treatment was the same as in the case above. It was several days before I could perceive that the patella was moved in the least; when first noticed it resembled more the faintest contraction of an artery than that of a muscle. From the progress of the case it was evident that the weakness of the contractions was owing to the almost perfect absence of muscular fibre, and not to the want of nervous influence. The last information I had from her was that she could walk the street by the aid of a cane without any artificial support to the limb. The paralyzed part in this case was well nourished, being thickly covered with adipose tissue, yet apparently destitute of muscular fibre.

The simple increase of the size of a limb by various modes of passive exercise does not afford the least evidence that there has been a gain of muscular power.

It is believed that enough has been said upon the matter of educating the will as the foundation of

all real success in the treatment of paralysis, more especially infantile, to direct to its consideration the thoughtful and serious attention of our medical brethren. If my experience, running through a long period, in the treatment of these and kindred difficulties is worth anything, I in all modesty believe it is entitled to a fair and impartial trial in conscientious and trustworthy hands.

I do not wish to be understood, from the preceding remarks, to assert that no other method succeeds, but that the mode advised has proved in my hands the most direct, rational, speedy, and satisfactory.

RECENT PROGRESS IN THE THEORY AND PRACTICE OF MEDICINE.

BY A. L. NASON, M. D.

VALVULAR LESIONS OF THE HEART.

PROFESSOR AUSTIN FLINT¹ concludes a lecture on cardiac lesions with the following summary of practical points:—

(1.) Cardiac murmurs may represent lesions which, if unaccompanied by symptoms referable thereto, enlargement of the heart not co-existing and the heart sounds normal, are to be considered as innocuous. The prediction of grave consequences, under these circumstances, is unwarrantable, inasmuch as they may never occur. Such lesions do not claim medical treatment, nor any extraordinary precaution; and it is desirable that the fact of their existence be withheld from patients, if this can be done with propriety.

(2.) Patients with valvular lesions are liable to suffer from functional disorders of the heart, arising from causes which have no pathological connection with the lesions. It is highly important to recognize, clinically, this accidental coincidence, in order to exercise a correct judgment as to the prognosis and treatment.

(3.) Various morbid conditions, other than functional disorder of the heart, may be accidentally associated with valvular lesions and more or less cardiac enlargement. These associated morbid conditions may be, in a great measure, responsible for symptoms and effects which seem to denote an advanced stage of the cardiac disease, whereas the latter may occasion but little inconvenience, provided these accessory, co-operating conditions can be removed.

(4.) Valvular lesions involving either obstruction or regurgitation, or both combined, and having led to considerable or even great enlargement of the heart, under favorable circumstances as regards associated morbid conditions, are often well tolerated indefinitely. There is less reason for a hopeful prognosis, in respect of tolerance, when there is considerable aortic insufficiency than in cases of aortic obstructive lesions, and those which occasion obstruction or regurgitation at the mitral orifice. The danger of sudden death from aortic regurgitation is lessened by coexisting mitral insufficiency.

(5.) In cases of orthopnea and general dropsy dependent on mitral obstructive or regurgitant lesions and enlargement of the heart, digitalis and active hydragogue purgation, repeated from time to time, not only

¹ Concluded from page 276.

often afford notable relief, but there is reason to believe that life is sometimes thereby much prolonged.

BAMBERGER ON BRIGHT'S DISEASE.¹

Bamberger has collected from the post-mortem room of the General Hospital at Vienna, during the last twelve years, 2430 cases with the anatomical diagnosis of Bright's disease. The division into interstitial and parenchymatous nephritis he does not attack in principle, but he differs from it on practical grounds, as numerous transformation forms and mixed forms exist; and he divides the whole series of cases into primary and secondary forms of Bright's disease.

The number of secondary cases amounts to 1623. Their symptoms were almost regularly so concealed by the fundamental disease that they were not diagnosed at the time, but they progressed with the ordinary symptoms, and many times even on their side they masked the fundamental disorder. Hypertrophy of the heart was found in this form, after excluding valvular disease, emphysema, endarteritis, and aneurisms, only in 3.3 per cent. The frequency of the relation to primary diseases is shown in the following table:—

PRIMARY DISEASES.	Acute.	Chronic.	Atrophic.
Tubercle, phthisis, and scrofula	47	257	77
Valvular disease of the heart	19	117	86
Pregnancy and puerperal process	80	56	16
Diseases of the urinary-excretory organs	11	72	51
Suppurative processes	42	77	10
Alcoholism and cirrhosis of the liver	16	68	33
Carcinoma	13	55	35
Emphysema of the lungs	6	51	28
Typhus	42	14	2
Syphilis	4	29	16
Scarlatina	18	—	—
Intermittent fever	1	9	3

It is to be remarked that in many of the cases here recorded it is certainly not a secondary form of Bright's disease which is to be dealt with.

To the primary form of Bright's disease Bamberger assigns the remaining 807 cases, of which 67 are described as acute, 357 as chronic, 383 as atrophic. It does not appear from the figures that this form is more frequent in men than in women. Cerebral hemorrhage occurred in 83 cases (2 acute, 29 chronic, 52 atrophic) not always combined with hypertrophy of the heart or endarteritic processes; inflammation of the brain substance in 28 cases, of the membranes of the brain in 10 cases, pneumonia (mostly croupal) in 163, recent pleurisy in 57, dysentery and extensive catarrh of the intestines in 109, general dropsy in 215 (33 each in the acute and chronic forms of Bright's disease, only 19 per cent. in the atrophic form). Pericarditis occurred 91 times; in acute Bright's disease twice, in chronic 30, in atrophic 55; endocarditis in 31, myocarditis in 5. Hypertrophy of the heart is noted 344 times, never in the right heart alone, 175 times in the left heart alone. Eccentric hypertrophy of the whole heart, always with more considerable participation of the left half, occurred 142 times (3 acute, 51 chronic, 88 atrophic); the right hypertrophy is frequently explained by the coincident emphysema. Eccentric hypertrophy was found on the left side only 107 times (4 acute, 38 chronic, 65 atrophic); simple hypertrophy 76 times (4 acute, 27 chronic, 45 atrophic); in 65 the

left side only was affected. Dilatation without hypertrophy occurred 19 times, the left side being affected in 3 cases only. Bamberger, after criticising the opinions held by others as to the causes of hypertrophy of the heart, accepts as its cause an increase of the mass of blood due to the diminished excretion of water through the kidneys. Even in primary cirrhosis of the kidneys a latent stage must be assumed, with diminished elimination of urine, on account of what is found anatomically, and because, according to Bamberger, it would be inexplicable whence the organism derives the excess of water under which it suffers, if it had not previously collected it. The pressure increasing with the mass of blood causes the left-sided hypertrophy; more blood also, and under greater pressure, passes into the venous system, first causing a dilatation of that system, but finally leading also to dilatation and hypertrophy of the right heart. Simple hypertrophy must, according to Bamberger, always be accompanied by dilatation; but as the mass of blood in the course of the disease may again become considerably diminished, the dilatation may in the same proportion disappear, whilst the hypertrophy must necessarily continue.

THE RELATIONS OF CARDIAC HYPERTROPHY TO RENAL DISEASE.

Dr. Robert Saundby² in a careful review of the various explanations of the cardiac hypertrophy in Bright's disease, says that since the time of Bright there have been four original explanations brought forward, and all other writers on the subject have adopted some one, or a combination, of these various theories. Traube, to whom we owe the observation of the hard pulse of Bright's disease, regarded the destruction of a large capillary area in the kidneys as necessarily causing so much obstruction to the circulation that, aided by the imperfect elimination of water, the blood pressure in the aortic system must rise and cardiac hypertrophy follow. Bamberger objected to this that the hypertrophy begins in the earlier stages of Bright's disease; moreover, it is present in chronic parenchymatous nephritis, in which no destruction of capillaries has occurred.

The next original explanation was that given by Dr. George Johnson, who pointed out the excessive thickening of the muscular walls of the renal arterioles, and suggested that the obstruction to the circulation offered by a state of tonic spasm in these vessels would explain their own alterations, the rise of blood pressure and the cardiac enlargement.

The third explanation is that which we owe to Sir William Gull and Dr. Sutton. They rediscovered the vascular changes described by Dr. Johnson, but drew attention more especially to the thickening of the fibroid tissues. They regard these vascular changes as primary and essential, the increased blood pressure and cardiac hypertrophy being their consequences, while the kidney disease is but a local expression of a general degeneration of the arterioles and capillaries attended by atrophy of the adjacent tissues. Although we may admit that when established these vascular changes do obstruct the circulation, and thus might be determining causes of cardiac hypertrophy, according to Thoma the fibroid thickening occurs in dilated vessels, so that the normal calibre is only exceptionally reduced. But in addition we have the fact that in a considerable proportion of cases of granular kidney cardiac hypertrophy

¹ Volkmann's Sammlung klin. Vorträge, 1879, No. 174. London Medical Record, February 15, 1880.

² The Birmingham Medical Review, January, 1880.

is found unaccompanied by the vascular changes. According to Ewald, this occurred in 4 out of 20 cases, and Dr. Saundby has been able to confirm the statement in about the same proportion of cases (2 out of 10). Finally, in chronic parenchymatous nephritis the occurrence of cardiac hypertrophy is not infrequent, but the vascular changes are quite exceptional.

The latest explanation we owe to von Buhl. He believes that the cardiac and renal changes proceed *pari passu*; the hypertrophy is to be attributed to the self-increased activity (*selbststeigende Thätigkeit*) of the heart. Myocarditis occurs very early, which may cause no alteration, atrophy, or hypertrophy of the organ, most frequently the latter. Relative stenosis of the aorta, as observed previously by Bamberger, with hypertrophied left ventricle, is thought by von Buhl to explain the increase of blood pressure in the aortic system. The relative frequency of myocarditis is admitted, also the stenosis of the aorta, in some cases, but not in all. Ewald has measured the circumference of the aorta above the valves in twelve cases, and found it to vary between 12.1 and 5.7 cm., the average being 7.6 cm., while the normal circumference, according to Bouillaud, is 6.3 cm., so that we cannot attach very much importance to it as a cause of cardiac hypertrophy.

Dr. Saundby, having failed to find any of these explanations quite satisfactory, returns to Bright's suggestions, that either the altered quality of the blood affords irregular and unwonted stimulus to the heart immediately, or that it so affects the capillary circulation as to render greater action necessary to force the blood through the distant subdivisions of the vascular system. Both these explanations rest upon the supposed impure state of the blood. Dr. Todd first pointed out the frequent coexistence of granular disease of the kidney with gout. Olivier has drawn attention to its occurrence among workers in lead. Dr. Johnson states that the disease is common in persons who "eat and drink to excess, or who, not being intemperate in food or drink, suffer from certain forms of dyspepsia without the complication of gouty paroxysms." He says that "renal degeneration is probably a consequence of the long-continued elimination of products of faulty digestion through the kidneys." The late Dr. Murchison was persuaded of the relation borne by contracted kidney to persistent lithæmia. Professor Semmola, of Naples, maintains the view that Bright's disease is a consequence of the blood dyscrasia resulting from suppression of the respiratory function of the skin. Dr. Saundby's own observations indicate the probability that prolonged and habitual dyspepsia is in many cases a precursor of this disease. Since, therefore, during the greater part of its course this affection does not lead to any diminution of the renal secretion, there is ground for believing in a blood dyscrasia depending upon other causes.

Dr. Saundby is of the opinion that the impure state of the blood acts as Bright suggested, by affording an unwonted stimulus to the heart immediately, and that this leads to a hypertrophy proportionately compensatory for the loss of renal secreting substance; that myocarditis is the cause of dilatation, and the subsequent hypertrophy takes place, as Buhl indicates, from over-nutrition and increased work from the greater capacity of the ventricle; that the rise in blood pressure is not a cause of the cardiac hypertrophy; and, moreover, that neither the state of the heart, nor the renal condition

and the blood impurity combined, are able to effect any increase in the tension of the aortic system.

But the high-pressure pulse of Bright's disease is a constant and now universally admitted fact. Traube asserted, not without reason, that he could diagnose granular kidney by the pulse alone. But a great step was taken when Mahomed proved that this rise in the blood pressure precedes the occurrence of albuminuria, the development of which he watched at the termination of scarlatina. Here there is no question of structural change in the heart or arterioles; the sole condition present is that of faulty elimination, due to the morbid state of the skin. When to this constipation is added, the blood pressure rises, blood crystalloids appear in the urine, and, if not averted by a sharp purge, albuminuria follows. Moreover, Dr. Mahomed has recorded cases of high arterial tension, sometimes accompanied by albuminuria in young dyspeptic patients free from cardiac hypertrophy, and Dr. Saundby has published similar cases. In both it is suggested that in these young persons we may have to do with the condition which gives rise to granular kidney later in life.

Dr. Murchison says, "So often have I observed albuminuria associated with hepatic disorder, which has disappeared completely and permanently when this has been set to rights, that I have little doubt that we have in the liver a cause of albuminuria to which attention has not hitherto been sufficiently directed. The pathology of the albuminuria in these cases may be similar to that of certain cases of diabetes already referred to, the liver having too much work to do, and permitting some albumen to pass through in a form which cannot be assimilated; or possibly there may be some defect in the destructive functions of the liver, in consequence of which the albuminous matter, instead of being converted into urea, does not even reach the stage of lithic acid. It is possible that in many of the cases now referred to the albuminuria may indicate an early stage, not yet described, of the contracted or gouty kidney; yet it is certain that the symptoms may persist or recur during many years without any other symptom of renal disease, and with but little impairment of the general health."

Finally, Dr. Saundby thinks that as the rise in blood pressure precedes all structural changes, and as the theory of vaso-motor action is inconsistent with the augmented secretion of urine, we may assume an increase in the capillary resistance as the other factor, which, combined with the augmented cardiac energy, determines the characteristic pulse of Bright's disease.

Dr. Saundby suggests the following practical conclusions:—

(1.) In chronic Bright's disease the augmentation of the cardiac function is compensatory to the renal defect. This view confirms the propriety of the practice of administering digitalis in these cases. But as far as possible elimination should be favored by the skin and bowels, while the diet should consist of elements containing as small an amount of urea-forming substances as the general condition of the patient may warrant.

(2.) The high-tension pulse indicates a high degree of toxæmia and relative failure of the kidneys. As the toxic material in the blood stimulates the heart (Israel and Grawitz) and probably the kidneys (Heidenhain) without raising the blood pressure, polyuria or even albuminuria may precede any change in the state of

the pulse. Careful examination of the urine is therefore of the greatest importance for detecting the earlier stages of the condition which leads to granular degeneration of the kidneys.

Hospital Practice and Clinical Memoranda.

ON CERTAIN UTERINE DISPLACEMENTS.

BY CLIFTON E. WING, M. D.

THE following cases will serve to illustrate the varied and at times severe symptoms occasionally accompanying certain uterine displacements, which are not at all uncommon, but which are often either not recognized by the physician when he makes his local examination, or considered so slight as to be of little or no importance, and not sufficient to account for the pains and aches of which the patient perhaps complains. They will also show the relief of symptoms to be afforded in many of these cases by a proper use of uterine supporters. Few physicians at the present day fail to recognize, on uterine examination, a well-marked instance of flexion or version, or a pronounced example of prolapse; but the cases I refer to are those where the uterus, retaining nearly or quite its proper axis in the pelvis, sinks lower than the normal position, yet does not descend so far as to constitute the "prolapse" of the general practitioner. That sometimes a uterus will be found so low in the pelvis that the cervix is far back in the hollow of the sacrum, resting, as it were, upon the floor of the pelvis, and yet the patient suffer little or no inconvenience, is without a doubt true; but that in other cases a much less degree of "sagging" will give rise to severe symptoms is equally the fact. The same is true of other uterine displacements. For example, every now and then a patient comes along with a perfectly marked retroversion which does not incommode her in the least, yet the physician who should reason from a case or two of this kind that retroversio uteri never caused trouble would be sadly in error.

CASE I. Mrs. T., aged twenty-five, consulted me at the request of her brother, a physician, and gave the following history. She had been married within a year. Never pregnant. Menstruation, which appeared at the usual age, is always regular, but accompanied by excessive pain. She dreads its appearance, always takes to her bed at once, and is often forced to resort to anodynes, which, however, never give her complete relief. The flow lasts five or six days, and is normal in amount. The pain is most severe the first two days, but she is obliged to remain quiet the whole time, else the pain increases. Leucorrhœa not a troublesome symptom. Between her menstrual periods she has some backache at small of back "when she gets tired." Can walk a mile or more, but not without backache afterward. Micturition normal. Slight tendency to constipation, for which she occasionally takes medicine. Appetite good, and general condition excellent. She states that she was formerly treated for "stricture of the uterine canal," which she was told was the cause of her pains when unwell. The uterus was dilated with tents at short intervals extending over a number of months, but she did not derive the expected relief, and now for a long time has had no treatment.

On examination, a uterine probe, a common sound, and lastly a Peaslee sound (the largest ever used) were successively passed to the fundus without meeting with noticeable obstruction. There was marked tenderness of the interior of the uterus; for some time even the most careful use of the probe causing severe pain, which lasted for hours. The whole organ was congested, swollen, and enlarged, and occupied the position previously referred to; that is, it was low in the pelvis, the cervix tending toward the concavity of the sacrum, the normal axis being retained.

There were two conditions present, either of which might account for the dysmenorrhœa. One was the inflamed, tender state of the interior of the uterus; the other, the position of the organ. Either condition might produce the other. An inflamed endometrium would be likely to induce an afflux of blood to the whole organ, increasing its weight, and thus its tendency to sink in the pelvis; while a uterus from any cause occupying a low position is liable to a chronic hypostatic congestion, which not only may, when increased by the monthly flow of blood to the parts, be of itself a sufficient cause of dysmenorrhœa, but, as would be supposed, is often followed after a while by a congested, and later a tender, inflamed condition of the uterine cavity. Which condition was the primary one in this case could not be determined.

For a while the patient was treated with local applications to the interior of the womb, made at intervals of about a week, in order to see if the use of a supporter might be avoided. In some of these cases such treatment suffices. As the local irritation is alleviated the congestion abates; the organ, diminished in size and weight, recovers its normal position without further aid, and the patient is relieved. I have known several marked instances. Often, however, this treatment alone will not bring about the desired result. In this case the effect was not satisfactory, although there was perhaps some slight decrease in the pain at the periods, and after a fair trial I advised the resort to a supporter, and fitted one. The patient soon found that her backache was less troublesome, and that she was able to be about on her feet without getting quickly tired out, as formerly. The applications were continued for a while, until they ceased to give much pain and the uterine cavity was no longer especially tender to the touch of the sound, and then stopped.

The patient lately came back to report. She had had less suffering when unwell than ever before, some of her periods being free from all severe pain, but for the last two periods there had been pain the first day. The pessary which she had worn for months had chafed a little at one spot, and I recommended her to go without it for a short time on this account. There was some return of the intra-uterine tenderness, which will need a little attention. She finds that now, even when without her supporter, she suffers less with backache than before she wore it, but I have advised her not to attempt to dispense with its use permanently yet. Eventually, she will probably be able to do without it.

Stricture of the uterine canal is not infrequently diagnosed as a cause of dysmenorrhœa, when in reality no "stricture" exists. When there is an inflamed condition of the lining of the womb the calibre of the canal is often much diminished by the coincident swelling, and in cases of displacement leading to hypostatic congestion the consequent œdema and swelling of the uterine tissues often leads to the same

narrowing of the uterine canal, which is most readily detected with the sound in the neighborhood of the os internum, that being normally the narrow part. But to treat such cases as though this secondary condition were the prime cause of the troubles present does not seem rational.

Again, when the examiner finds difficulty in passing a sound, he is very apt to jump to the conclusion that a stricture is present, when perhaps such is not the case, and the fault is his own. Where the old-fashioned cylindrical speculum is used (and no one at the present day would base a diagnosis of stenosis of the uterine canal upon difficulty in passing the sound by the touch alone, and without the use of any speculum), it is, in many cases, an impossibility for any one to be at all sure whether a stricture is present or not; for, owing to the fact that the uterine canal is not in a line with the speculum when the latter is introduced into the vagina, but often nearly at right angles with it, a sound cannot always be readily passed through this speculum into a normal uterus. The valvular specula are rather better in this respect, but may lead to error in another way, as I have several times seen. Unless carefully managed, the end of that blade which lies along the anterior vaginal wall may very easily be pressed against and be made to indent the anterior wall of the uterus, so as to obstruct the uterine canal to a degree that the sound will not readily pass. The Sims speculum shows its superiority here as elsewhere, but its proper use necessitates the aid of a trained assistant.

CASE II. Mrs. N., aged thirty-six. Married at eighteen. Mother of four children, youngest four years old. Has had her present troubles particularly since the birth of her last child, but suffered somewhat before. Had several miscarriages between her first and second children, and with some of her confinements had marked relaxation of the pelvic ligaments, getting much relief at these times by wearing a broad belt buckled very tightly about the pelvis. Menstruation began at thirteen. Always regular each three weeks. Time of flow, six days. Amount normal. No dysmenorrhœa, except slight discomfort first twenty-four hours. Of late years has kept her bed when unwell, by advice of physicians. She formerly had much "bearing down" on walking. Has not had it of late, "simply because she has not walked any distance for four years." When she is on her feet any length of time she has severe pain in her bowels, which is relieved in a measure by hot applications to the abdomen. No backache. At one time suffered much with her head and neck, but does not at present. Cannot walk up and down stairs without subsequent distress, and now never attempts to do so, always making use of an elevator which has been put in the house for her benefit. Her husband tells me that when they were at the sea-side during the summer, she, by actual count, spent sixty-eight days of the time in bed; but being a woman of great energy, when at home she rides out nearly every day, and manages to shop by always sitting as much as possible when in the stores. Her previous attendant thought a supporter might perhaps give her some relief, and called another physician in consultation about the matter; but the consultant advised against a pessary, owing to the tenderness discovered on examination.

In this case the same malposition was found. There was a rupture of the cervix uteri, with eversion, and the womb was larger than usual from subinvolution.

While there was quite marked tenderness of the womb itself, which the displacement alone might account for, there was no tenderness of the surrounding tissues, and the organ was freely movable. Under such circumstances a supporter is not contra-indicated, but it is the proper thing to try. Tenderness involving only the uterus, and not extending to the neighboring parts, is no impediment to the use of a supporter; for, properly applied, the latter does not touch the womb.

A pessary was fitted, and the patient cautioned not to expect too much, as nothing could be promised in such a case, and advised to keep rather quiet for the present. She reported in a few days, perfectly delighted, and saying she felt young again. She had astonished her servants by running up and down stairs, and her friends by honoring them with evening calls on foot. The evening after the supporter was applied she spent at the theatre. Moreover, she did not suffer from her indiscretion. Her improvement has continued, and lately she withstood a physical and mental strain, consequent upon sickness and death in her family, which she declares would have completely broken her down but for her greatly improved condition.

CASE III. Mrs. C., aged twenty-four. Married at eighteen. Two children, six and four respectively. Two miscarriages, the last two years ago. Menses at fifteen. Always regular. Time of flow seven to ten days. Amount large. Has always had more or less dysmenorrhœa. Better in this respect after her first child, but worse again after her second. Has had uterine symptoms ever since her first child, but has been much worse since her last miscarriage (two years ago), since which she has spent most of the time in her bed. Has constant severe backache, pains in each side and down her limbs. "Is almost crazy" with her head. Unable to sleep, although using anodynes. Nervous, discouraged, and hysterical. Looks haggard and worn out. When she is unwell, and also when she attempts to keep about on her feet, has very severe pain in the right side, which she has been told comes from the ovary. Has also been told that she would never carry a child to term if she became pregnant.

She has been under the care of a homœopath, who applied a pessary, which she shows, and which is so poorly shaped that it could not be of benefit. It soon gave her pain, and she had it removed. Failing to get relief, she was induced to enter as patient an institution whose claims for support are frequently brought before the public by its philanthropic friends. Here she was religiously kept in bed during her stay. That there was an abnormal position of the womb was apparently made out by her attendants, but the plan of treatment which they wished carried out was a decidedly curious one, namely, once or more each day she was to get upon her knees in bed, bury her head in the pillow, elevate her body as high as possible,—thus standing on her head, so to speak,—and remain in this position as long as she could. She tried the method but once; for finding that the head symptoms were anything but benefited by it, she positively declined to try it again. After a stay of five months in the hospital (kept in bed all the time), she was told that her case was a chronic one, and that the institution was not intended for such. She returned home, supposing that her troubles were incurable, and wholly discouraged. I was asked to see the patient by the physician who was next called to her, and requested by him to take the case.

The examination showed much the same condition as in the other cases, except that there was marked tenderness of the right utero-sacral ligament, as is not very uncommon where these ligaments are for a long time overstretched. This condition would account for the pain in the side, which had been attributed to the ovary. It caused some trouble in the fitting of a comfortable supporter. From the first the patient was urged to leave her bed and keep about the house. At the third visit she was found sitting up and playing the piano, and in a few weeks was able to come to my office for what attention was necessary, and to take charge of her household affairs. She has worn her supporter with comfort. I have not been able to discover any condition which would prevent her from carrying a child to full term if she should become pregnant, nor any reason why she should not.

In this case, as in the previous one, there existed rupture of the cervix uteri, with eversion. No attention was paid to the condition, however, as I feel convinced from observation of very many cases that the importance of this lesion has been very much overestimated, and that except in a small minority of cases it does not call for treatment.

CASE IV. Mrs. S., aged twenty-eight. Married at eighteen. No children. One miscarriage the year after marriage at about the third month, following a sea voyage, during which she was very ill with seasickness. Menstruation began at sixteen. Before the miscarriage always regular. Time of flow nine days. No pain. Since the miscarriage she has been very irregular, flowing too frequently, and has had severe dysmenorrhoea each time. She has constant backache, "beating down," had feeling in head, etc., etc., in short, marked uterine symptoms, which are all increased at the time of her periods. She has been under medical care since she miscarried (now over eight years ago), at first with "regulars," and not having got relief, of late with "irregulars." Each doctor seemed to treat the case differently from the others, but no one helped her. Her first physician (the one who attended her when she miscarried) told her to wear a supporter, and supplied her with a vaginal bag, which she introduced into the vagina and distended with air. This soon caused pains and tenderness, in fact, increased her sufferings, and after a few days was discarded. Since that time no one has mentioned a supporter to her.

During the past five years she has had constant nausea, with occasional vomiting. This trouble has been increasing, so that for over a year she has not been three days without vomiting, which has not unfrequently taken place "a dozen times a day." Her appetite is poor, and she eats "little or nothing." Is somewhat anæmic, but not emaciated. She feels "used up," and for the past four months has kept her bed, and for the last three months of the time has had constant slight uterine flowing. Is unable to sleep, even with medicines. In this state of affairs she called in a member of our society, who, seeing the nature of the case, asked me to see the patient and treat her. Both the lady and her husband were exceedingly anxious to have children. The uterus was found subinvolved, and its position as in the other cases reported. There was a slight discharge of blood from the os uteri, rather increased by the use of the sound. I made an astringent application to the uterine cavity to check the flow temporarily, and fitted a supporter.

Within a few days the patient was about the house.

The supporter needed alteration from time to time, but within six weeks the lady was able to come to town to my office for the necessary attention, and to go about visiting the stores. *She had neither nausea, vomiting, nor flowing from the time the pessary was applied.* Menstruation was perfectly normal for two months. A week after it should have appeared for the third time she came to see me, saying that for about ten days she had had slight nausea each morning, but nothing like as severe as that which she had suffered from so long. She stated that her appetite was very good, and that she had an almost uncontrollable desire for certain dishes, mentioning lobster-salad, which she had not eaten before for years. I expressed the opinion that she was probably pregnant. I met her a few days ago. It is now three months or more since she menstruated, and she has little doubt of her condition. She reported herself as feeling better than for years.

The sudden and complete relief of such severe nausea and vomiting as were present in this case, simply by the use of a supporter to lift the uterus, is interesting and suggestive.

Slight nausea and vomiting, referable to uterine conditions other than pregnancy, are not very rare, and these symptoms, when coincident with a displacement, are often at once relieved or ameliorated by keeping the uterus in its proper place.

Now in the first months of pregnancy, when reflex symptoms are most common, the enlarging womb, until by its growth it lifts itself out of the pelvis, occupies a lower position than usual. If in the non-pregnant woman such severe symptoms as were present in this case can be completely relieved by lifting the womb, — regarding the low position of the early pregnant uterus as a possible factor in the causation of nausea and vomiting, — it does not seem unreasonable to suppose that in certain cases, particularly those where the sinking of the organ is exaggerated, the proper use of a supporter may prove an efficient agent in affording relief from this distressing and at times dangerous complication. It seems to me that the subject, although mentioned here and there, has not received the attention which it merits. Certainly the experiment of a supporter is worthy a trial in those cases at least where otherwise a provoked miscarriage would be resorted to. It is needless to add that the pessary should be used with skill and care.

Reports of Societies.

PROCEEDINGS OF THE OBSTETRICAL SOCIETY OF BOSTON.

C. W. SWAN, M. D., SECRETARY.

THE TREATMENT OF THE PLACENTA IN ABORTION.

APRIL 12, 1879. DR. LYMAN stated, as bearing upon the recent discussion as to the propriety of immediate removal of the placenta or delay until severe symptoms demanded interference, that he had been called on the 13th of March to a patient who was aborting. She was perfectly comfortable, and there was not a drop of blood escaping, but the ovum was partly extruded. Emmet's forceps were applied without difficulty, and it was thought that the whole placental mass was removed. This process was followed by profuse hæmorrhage, requiring tampon. On the first of April severe hæmorrhage recurred; the forceps

were again employed, and a mass of placental tissue as large as an almond was extracted. The bleeding then ceased. — Dr. FIFIELD said he had known an abortion to occur at the third or fourth month, followed by entire relief for many months, to be succeeded by another pregnancy and another abortion, when both placenta were thrown off together. Many years ago he had had a patient who discharged a small, perfectly fresh placenta which had been retained six weeks after a miscarriage which had been otherwise complete.

Dr. MINOT said he thought it was usually easy to explore the interior of the uterus with the finger, and remove any remains of the ovum which might be adherent, in cases of hæmorrhage following abortion. The woman should be etherized and placed upon her left side, with the knees well drawn up. The uterus should be firmly depressed by the left hand of the operator applied externally behind the pubes, the right hand introduced into the vagina, and the forefinger (sometimes two fingers) passed into the cavity. Unless the patient be etherized the rigidity of the abdominal walls is often so great that the uterus cannot be felt by the hand externally, or be sufficiently depressed to bring the cavity within reach of the exploring finger. When the woman is very fat, it may be difficult or impossible to reach the cavity of the womb with the finger, and it then becomes necessary to search for the retained growth with forceps; but this is rarely the case.

Dr. LYMAN said that in his experience it was not such an easy matter to press the uterus down so as to be within easy manipulation unless the hand were introduced into the vagina. This is not always stated. Of course, with the hand in the vagina, the finger, if properly managed, should go easily enough to the fundus if the os be sufficiently opened.

THE USE OF ERGOT.

MAY 10, 1879. Dr. WELLINGTON, referring to a recent discussion in the society upon the treatment of the placenta in abortion, suggested that ergot, according to his own experience, was well worth trying. Time after time he had got the mass away in that manner after two or three doses. The action of the drug upon the uterus was well known and recognized. It is given in the unimpregnated state of the organ to lessen its size, or to stop hæmorrhage. In one case, indeed, the remedy seemed to have no effect, as the placenta remained in the womb for a fortnight. It was afterwards discovered that the patient had been taking the fluid extract of cubebs. Dr. Wellington remarked that ergot had not received its due recognition in the late discussion. — Dr. LYMAN said he had not spoken slightly of ergot. He was formerly more in the habit of using it than now, however. Everything which came away well was ascribed to the effect of ergot, but subsequent cases did as well without it. The point of his remarks in the discussion was upon the question of interference by the placental forceps and other means, procedures which his late experience, as detailed at the last meeting, had not favored. — Dr. HODGSON stated that his experience with ergot was not entirely in accordance with that of Dr. Wellington. The quality of the drug may not always be what it is expected to be, but aside from this, though given in full doses, he had found its ac-

tion uncertain even at term. Still, his reliance had been either upon the ergot, or time without the ergot.

EPITHELIOMA OF THE CERVIX REMOVED BY CURETTE AND SCISSORS.

Dr. BOARDMAN reported the case, which came under his observation in the previous March. The history of the case presented no remarkable features except an almost entire absence of symptoms, the patient having complained for some time merely of a leucorrhœa which had occasioned some annoyance. Upon examination, the disease was at once recognized as epithelioma, and from its obviously circumscribed condition the operation for its removal was advised. Anteriorly there was about a quarter of an inch of the vaginal portion free from disease, and posteriorly about half an inch. The cervical canal was also free down to the level of its junction with the vaginal portion. The patient was not seen again until the last of April. During the interval she had severe hæmorrhage with grumous discharge for four weeks. Examination showed that a portion of the diseased tissue had come away, so that the above-mentioned limits could be very accurately determined. In order to save the healthy membrane for the formation of a new cervix, the operation, done on the first of May, was performed with the curette and scissors, the diseased tissue being removed piecemeal until what remained appeared to be healthy to the sight and touch. The result of the operation gave the reason for reporting the case, for it was found that the more usual method of procedure advised for such a case, namely, amputation by means of the galvano-cautery wire or the *écraseur*, would not have proved efficient for the entire removal of the disease, since there were found three separate tongues of this tissue, which reached to a considerable distance upwards into the supra-vaginal portion, beyond the level which would be included by amputation.

Dr. SINCLAIR said that he agreed entirely with Dr. Boardman as to the method of treatment, as there was nothing equal to the touch in detecting the site and extent of the diseased tissue. He thought, however, that there would be a recurrence of the disease in the case described. He had had two or three similar cases during the past year, in all of which the disease had recurred and in one of which it had already ended fatally. He did not think the operation hastened death, which occurred about five months after the first and one month after the second operation.

Dr. HOMANS observed that he could not see why it was more sensible to remove a part of the cervix than a part of the breast in cases of cancer of that organ. Even where the whole breast is amputated, most patients die within two or three years afterwards, although in exceptional cases there may have been no recurrence during a life prolonged twenty or even forty years. Dr. Homans said he applied these remarks to all forms of cancer, the comparative immunity from return in cases of cancer of the lip being principally owing to the fact that in these the disease is discovered and removed so early.

Dr. BIXBY mentioned the case of a patient who after the process of gouging followed by the application of nitric acid, went three years in comparative comfort and freedom from pain and hæmorrhages. These ultimately recurred, and were again relieved in the same way. At the last hæmorrhage preceding her death there was very little of the uterus remaining.

DR. LYMAN remarked that very many of the cases of epithelioma of the cervix with much hemorrhage will be benefited by almost any sort of interference with them. A very healthy-looking patient from Sax-onville presented one of the most extensive specimens of this disease he had ever seen. After a series of very severe hemorrhages, the ulcerated cavity of the cervix was packed with cotton-wool saturated with subsulphate of iron, and the patient went home. Six weeks later her physician stated that she had not been so well for years, and up to that time there had been no recurrence of the hemorrhage. More recently two other and similar cases had been treated with the same good result. Though not curative, the treatment prolongs and renders comfortable the life of the patient.

DR. BOARDMAN observed that Braithwaite, of London, recommends the application of the subsulphate or the perchloride of iron as the best agent, giving immediate though temporary relief to the more urgent symptoms, a result which he himself had observed in one instance.

DR. LYMAN remarked that the stenosis which follows is to be taken into account, even if the operation be successful.

DR. MINOT reported a case of

URGENT VOMITING IN PREGNANCY.

The patient was a young married lady, previously in good health, who had aborted, without obvious cause, in October last, at about the eighth week of her first pregnancy, having had no vomiting and up to this time but little nausea. March 7th, being again about eight weeks pregnant, she began to be troubled with occasional vomiting, which increased in a few days so as to become very annoying, and was soon accompanied by excessive salivation. The cervix and os uteri seemed healthy to the touch; tongue clean; pulse natural; urine contained no albumen. By March 15th the stomach would retain no food, and the patient was nourished by enemata of milk and beef tea, half a pint of each alternately every four hours; each enema also contained half an ounce of brandy. These were well retained, and were continued without interruption, day and night, during the remainder of the treatment. A quarter of a grain of morphia was injected under the skin at night, and a soft rubber ring pessary was placed in the vagina, so as to press gently up behind the cervix, with the view of supporting the uterus under the violent pressure caused by the vomiting. Any excitement, even an accidental loud noise in the room, would cause urgent retching and rejection of anything which happened to be in the stomach. Several times the patient went forty-eight hours without swallowing anything but water. The elbows became excoriated by the pressure caused by her position while vomiting, and had to be protected by pads of cotton. The pulse gradually rose to upwards of 130 in the minute; there was much emaciation, prostration, loss of sleep, and depression of spirits. The salivation became extremely annoying.

March 20th, Ridge's food was tried in small quantities every hour. This was well borne, and on the 22d she retained a pint of it during the day; but on the 23d it was rejected, and even the enemata were partly returned unaltered. The patient's condition being considered critical, Dr. Wyman, of Cambridge, was asked to see her in consultation, with a view to the

induction of abortion. It was decided to wait, and the next day there was some improvement. The treatment was kept up, and patient continued to do well. March 28th she began to chew beefsteak. April 3d the vomiting and salivation had ceased, and she took a fair diet. Pulse 96. She drove out. The enemata were discontinued.

April 25th the patient took cold, and coughed a great deal. This seemed to bring about a return of the vomiting and salivation, which soon became as severe as before, and the patient's condition was again very discouraging. The same treatment was employed, with the addition of five drops of a solution of atropia (one grain to the ounce) and ether spray to the abdomen. The morphia was given in suppositories. There was but little improvement up to the present time.

[Dr. Minot subsequently reported that the patient began to amend on May 14th. She continued to improve, and was nearly well on the 24th, when, after a drive, she had a chill and a return of the vomiting. The symptoms, however, were less severe than before, and by June 1st there was permanent relief. On the 9th she took a short walk, and from this time she remained well. Quickening occurred May 22d; June 10th the womb could be felt above the pubes.]

So far as treatment had any effect in this case, benefit seemed to be chiefly derived from the rest to the stomach and the nourishment afforded by the enemata, to the morphia at night, and to the cautious feeding with Ridge's food, which was done by a skillful nurse. Some comfort was given by ether spray to the epigastrium, but there was no real advantage from its use. The atropine was used with a view to control the salivation, with less success than was hoped, but still with some apparent benefit.]

DR. C. P. PUTNAM referred to the case of a patient suffering from the vomiting of pregnancy. The lips of the cervix were not ulcerated, but were marked with reddish streaks. The symptoms were very much relieved by the application of the tincture of catechu on cotton. At the same time two or three drops of the tincture of nuxvomica were administered, which might possibly have contributed to the improvement.

DR. BOARDMAN mentioned the reported cases of the successful employment of enemata of chloral and of continued pressure at the epigastrium for the relief of the constant and serious vomiting of pregnancy.

DR. J. J. PUTNAM exhibited

A FIBROID TUMOR OF THE UTERUS,

which he had removed on the day of the meeting from a patient who had died of gangrene of the lungs at the Danvers Hospital. The tumor was multiple, the largest portion being of the size of a child's head at birth, with a small and distinct pedicle. There was also a fibroid polypus, with a distinct pedicle, in the uterine cavity.

PATHOLOGICAL CHANGES IN SEPTICÆMIA AND PYÆMIA.

DR. E. G. CUTLER presented a paper upon the above subject, which was read at the annual meeting of the State Medical Society. In addition, Dr. Cutler stated that septicæmia is due to the absorption of decomposed products. The reason why Dr. Chadwick's cases improved was because the process of absorption was arrested by the antiseptic injections, and the process of cure, indicated by the symp-

toms of the disease, enabled to go on to a successful issue. In septicaemia the initial chill may as likely be absent as present, and intercurrent chills never occur in pure septicaemia. The temperature, at first high, as the disease progresses reaches the normal point, or may even sink below it, while the pulse and respiration increase in rate. In pyaemia, on the other hand, with each pyaemic focus there is a chill and a corresponding elevation of temperature. In pyaemia, if you can reach the source of infection, you may be able to arrest the symptoms. A man, for example, received an injury. It was necessary to amputate the thigh. He did well until the fourth day, when symptoms of general infection supervened. The patient was etherized. The surgeon slit up the femoral vein and pulled out the thrombus; the same was done with the artery. Then the symptoms disappeared, and the patient recovered. It is impossible to tell from all of Freund's cases whether they are all septicaemia, pyaemia, or septicopyaemic. Hueter, in his surgery, gives a case as follows: A woman had abortion, and the cervix was ruptured. Four weeks after delivery she had pyaemia and died. Behind the broad ligament was a focus. A wash in such a case would do no good. The two diseases run into each other frequently. The clinical history is not always sufficiently marked for a diagnosis. Mr. J. Hutchinson considers inflammation of the skin as not uncommon in pyaemia, which is further characterized by icterus, sudamina, bulke, little hemorrhages with a pustular centre, occasionally a scarlatinial rash. At an autopsy which occurred two months before, in a case of spontaneous pyaemia, large bullae were observed.

Dr. Bixby said he had seen quite a number of cases of death from septicaemia after ovariectomy. These were characterized by dry tongue, great debility, rapid, weak, and small pulse, the absence of localization of the disease within the organs, the invariable absence of even the slightest evidence of peritonitis, a perfectly flat abdomen. The operations in these cases have been various; in some instances complicated, in others simple. In one case a cyst of the broad ligament, free from adhesions, had been removed by a small incision with perfect ease under antiseptic precautions. In one single instance, that of a case of papilloma of the ovary, where the operation was more complicated, a local affection manifested itself in the form of great enlargement of the cervical glands. Dr. Bixby was disposed to think, from his observations of septicaemia, that there was a difference between this affection and pyaemia, from the fact that there had been in nearly all these cases less tendency to multiple abscesses.

Dr. FIFIELD asked Dr. Cutler to state the broad grounds of distinction by which the two diseases, pyaemia and septicaemia may be recognized.

Dr. CUTLER referred Dr. Fifield to the last edition of *Bilroth* as containing the clearest answer to the question. In the main, the distinctions were these: Both are general diseases. In septicaemia there is absorption of decomposing matter. In pyaemia there is the absorption of matter, together with bacteria, from a wound, or from foci in the immediate vicinity of a wound. In the former the symptoms are those of general waste, changes of decomposition in vital organs. In the latter there are a good many metastatic abscesses, or a good deal of pus, in the bones, brain, etc.

Recent Literature.

Urinary and Renal Diseases. By WILLIAM ROBERTS, M. D. Physician to the Manchester Royal Infirmary, etc. Third American from the third revised and enlarged English Edition. Philadelphia: Henry C. Lea. 1879. Pages 631. Illustrated.

We have here the third edition of this highly esteemed work, the second edition of which was published in 1872. The changes comprise accounts of Russell and West's method of estimating urea, of the filaria discovered in cases of chyluria, by Dr. Lewis, and of the author's method of estimating albumen. The views of Sir W. Gull and Dr. Sutton on antero-capillary fibrosis in Bright's disease are briefly set forth, as also the researches of Dr. Dickinson on the pathology of diabetes. Dr. Roberts's treatise continues to be a most valuable guide to the students of clinical medicine.

The North American Review for April has for its leading article a paper entitled *McClellan's Last Service to the Republic*, which covers the whole period of McClellan's military career, from the flank movement to the James to the battle of Antietam. It is intended to vindicate the general against the charge that he was over-cautious and unnecessarily slow in his movements, and contains many statements of an interesting character. Sir Francis Hincks contributes a paper on the Relation of Canada with the United States. The author's principal object is to show that the recently enacted Canadian tariff is not an act of retaliation against the United States for their refusal to establish reciprocal free trade between the two countries in products that are natural to both. Canada, he says, is desirous of renewing the reciprocity treaty, and is ready to concede all reasonable demands. The Rev. David Swing writes about the Failure of the Southern Pulpit. According to him, the Southern pulpit is without influence on public opinion in the South, whereas it might be, and ought to be, a great engine for the moral and material regeneration of the people. The discussion of the Third Term question, begun in the February number of the *Review*, is continued in the present number by the Hon. George S. Boutwell, who insists that, whatever may have been the practice and the teaching of "the fathers" with respect to a third term, circumstances make it in the highest degree expedient that General Grant be again elected to the presidency. Charles Stewart Parrell sets forth the reforms in the laws of land tenure which are advocated by himself and his political associates, under the heading, *The Irish Land Question*. The Book Notices are by Mr. Edward Cary.

—Dr. Charles W. Earle thus disposes of the "cinchona cure" for drunkenness: "I do not say that not a single person to whom this drug has been administered has stopped the use of liquors; but I do say that not one with whom I have come in contact has, and in many cases its use has rekindled an old desire which by resolution and education had been nearly conquered. I do not say that in every case following the administration of this nostrum injury to the patient has come; but I do say that in every case which has fallen under my observation this has been the result."

Medical and Surgical Journal.

Remittances by mail should be sent by money-order, draft, or registered letter to HOUGHTON, OSGOOD AND COMPANY, Boston, Mass.

THE ARGUMENT OF THE COUNSEL FOR THE SOCIAL SCIENCE ASSOCIATION BEFORE THE JOINT LEGISLATIVE COMMITTEE ON PUBLIC HEALTH.

WHATEVER may be the fate of the draught of the proposed act to regulate the practice of medicine in this State, at present under consideration by a committee of the legislature, there can be but little doubt that sooner or later some steps will be taken in this direction. Some of our readers evidently still entertain serious misgivings as to the wisdom of the present measure, and others perhaps would distrust any measure likely to be made law. We find the arguments in behalf of the proposed act very forcibly and eloquently given by Mr. Pillsbury, the able counsel of the Social Science Association, and hope those interested in the question will read his remarks before the legislative committee, from which we venture to make a few brief abstracts, without indorsing every phrase which may have been used, only regretting that want of space puts it absolutely out of our power to do them and the subject greater justice.¹

Mr. Pillsbury defines the bill as one to regulate admission to the practice of medicine. — that, and nothing more; and then goes on to say: The one thing which it seeks to accomplish is that when a person goes before the public as a common practitioner of the healing art he shall be endowed with a fair moral character, and shall know something of his business. It endeavors to guard personal rights, and to provide against ill-defined or arbitrary power. The purpose of the petitioners is to obtain some statutory regulation of admission to the practice of medicine, not statutory regulation of the practice itself. They have no design to abridge individual freedom of choice or of opinion. They desire that all shall be allowed to practice medicine as they like, provided they come to that work with fair and reasonable qualifications for it. Nothing is farther from the purpose of the petitioners than to interfere with personal rights. From time immemorial the legislature, for the protection of the public, has found it necessary to impose some restraint upon the right to exercise various callings, as you know. This bill relates to one which touches the health and the lives of the people more nearly than any other; and, in the name of a quack-ridden community, the petitioners ask you to lay upon this also such salutary restraint as the exigency demands.

I deny that there is anything in the bill which can

¹ For reference, the draught of the bill may be found in our issue for February 19th.

be properly characterized as discrimination. In so far as it raises any distinction between individuals or classes, there is a reason for it. The sufficiency of the reason is a matter of which you are to judge.

There is no question of schools here, for all the so-called schools are united upon it. The reason why certain medical societies have been described in the bill as the sources to which the appointing power may go in selecting the members of the board of registration is because these societies have exercised, under the authority of the State, for a period of years, the power to examine and approve their members, both as to character and qualifications, before admission. There is now, so far as those societies are concerned, some guarantee of the fitness of their members to practice medicine and to perform the duties pointed out by the first section of the bill. If the guarantee is not sufficient, the provision can be modified as seems best.

Comment has been made that the board, or a majority of it, is likely to consist of regular physicians. That is a wholly gratuitous and unwarranted assumption. If the proportionate representation indicated in the bill gives them a majority in the outset, the assumption that they will always continue to have a majority carries with it the assumption that neither the eclectic nor homœopathic societies are ever going to increase materially in their membership. The members of these societies do not believe this, nor do they object to this provision of the bill. They believe that respectable physicians of all schools, and of no school, if such there be, will work together to eradicate the evils against which the bill is directed. And have you the slightest reason in the world, gentlemen, to suppose that respectable men, acting under the sanction of an oath and under official responsibility, will undertake to approve or reject any person simply because he comes from a school whose practice they do or do not recognize as the best? Moreover, you will find that the board cannot ascertain and cannot know, until they have examined the applicant, whether he is allopath, homœopath, eclectic, or neither the one nor the other. If that is so, and we think the language of the bill is such as to make that clear beyond question, how are they going to discriminate, even if they would?

A word, now, as to the first clause of section four: —

"Any person who, at the time of the passage of this act, is a member of any society described in section one may practice medicine without further license so long as he remains a member of either of said societies."

I have already stated the reasons for which the present members of the societies are placed upon this footing, in my observations upon the first section of the bill; that there is some existing guarantee of their character and learning, they having been subjected to examination already, under the authority of law, by the societies themselves. They have been gauged by those most interested to ascertain their true capacity. We submit that it is a sufficient guarantee, and that this distinction cannot be reasonably objected to. You will note, also, that it applies only to those who are in the societies at

the present time. Hereafter not even this distinction will exist, but all comers will stand alike, regardless of their affiliations; and the licenses of members of the societies are subject to revocation, if occasion arises, equally with all others.

The tenth section might seem foreign to the purpose of the bill, but it is really one of its most important provisions. As the law is now interpreted, any person who styles himself a physician is a physician to all legal intents and purposes. That, Mr. Chairman and gentlemen, is substantially the law of Massachusetts to-day. Some reference has been made to the existing state of the law, and I desire you to note this carefully; all you need to make yourself a physician, under the law of Massachusetts, is to say so. Call yourself a physician, and you immediately are one, with all the rights, privileges and powers that attach to that vocation.

Under the statutes of Massachusetts — and I wish I had time to go into them in detail — many important powers are bestowed upon physicians. Duties are prescribed to be exercised by them which touch not only the property, but the health, the liberty, and lives of citizens. The power to issue certificates of the cause and manner of death is one; the power to certify for commitment to insane asylums is another, and so on. And who are they who are to exercise these functions? Any of these people who practice as physicians; any one who sticks up a sign calling himself doctor, — he, if cloaked however thinly with outward respectability, is legally as well qualified for the exercise of any of these powers as any other; and the result, in the one particular matter of death certificates, to which this tenth section has reference, is the concealment of a vast amount of iniquity. You have a letter here from perhaps the most experienced prosecuting officer in Massachusetts, who now holds the office of attorney-general, who has been engaged in the administration of criminal justice for twenty years, and who knows whereof he speaks. He has told you something about this, and I beg you to attend to what he says. Any one of these impostors and charlatans, however ignorant and vile, — and I don't intend to stigmatize any one who does not deserve it, — any one of them may issue a death certificate upon which the body of a murdered man, a strangled babe, or an aborted fetus may be smuggled away and concealed. Now I will produce one case — just one — to illustrate the law under which we live, to show you what a physician is in Massachusetts by law, what he may do by law, what he may be punished for doing, and for what he may not be punished. I will not go into the street for it. I will not ask you to take any man's word for it, neither of physician nor patient. The doctor is in his grave, and all his works have long since followed him thither. It is the case of the Commonwealth *v.* Samuel Thompson, in the sixth volume of Massachusetts Supreme Court Reports, page 134.

Samuel Thompson was the author and finisher of the "Thompsonian" system. He had the misfortune to be indicted for murder, in Essex County, in January, 1809, in a case which arose in his practice as a

physician. I will read to you briefly from the official report of his case. It is to-day the only authoritative exposition of the law of Massachusetts upon this subject [reading]: —

"On the trial, it appeared in evidence that the prisoner, some time in the preceding December, came into Beverly, where the deceased then lived, announced himself as a physician, and professed his ability to cure all fevers, whether black, gray, green, or yellow; declaring that the country was much imposed upon by physicians, who were all wrong if he was right. He possessed several drugs, which he used as medicines, and to which he gave singular names. One he called 'coffee,' another 'well-my-gristle,' and a third, 'rameats.' The deceased, having been for several days confined to his house by a cold, requested that the prisoner might be sent for as a physician. He accordingly came, and ordered a large fire to be kindled to heat the room. He then placed the feet of the deceased, with his shoes off, on a stove of hot coals, and wrapped him in a thick blanket, covering his head. In this situation he gave him a powder in water, which immediately puked him. Three minutes after he repeated the dose, which in about two minutes operated violently. He again repeated the dose, which in a short time operated with more violence. These doses were all given within the space of half an hour, the patient in the mean time drinking copiously of a warm decoction, called by the prisoner his 'coffee.' [Some similar evidence is here omitted.] On Monday he appeared comfortable, but with increasing weakness, until the evening, when the prisoner visited him, and administered another of his emetic powders, and in about twenty minutes repeated the dose. This last dose did not operate. The prisoner then administered pearl-sh mixed with water, and afterward repeated his emetic potions. The deceased appeared to be in great distress, and said he was dying. The prisoner then asked him how far the medicine had got down. The deceased, laying his hand on his breast, answered, 'here,' on which the prisoner observed that the medicine would soon get down and unscrew his navel; meaning, as was supposed by the hearers, that it would operate as a cathartic. Between nine and ten o'clock in the evening the deceased lost his reason, and was seized with convulsions, fits, two men being required to hold him in bed.

"After he was thus seized with convulsions, the prisoner got down his throat one or two doses more of his emetic powders, and remarked to the father of the deceased that his son had got the 'hyps' like the devil, but that his medicines would fetch him down. The next morning the regular physicians of the town were sent for, but the patient was so completely exhausted that no relief could be given. The convulsions and the loss of reason continued with some intervals, until Tuesday evening, when the deceased expired."

This man was indicted for murder. The court ruled that he could not be convicted of murder. Thereupon [reading]: —

"The solicitor general strongly urged that the prisoner was guilty of manslaughter, because he rashly and presumptuously administered to the deceased a deleterious medicine which in his hands, by reason of gross ignorance, became a deadly poison.

"The prisoner's ignorance is in this case very apparent. On any other ground consistent with his innocence it is not easy to conceive that on the Monday evening before the death, when the second dose of his very powerful emetic had failed to operate, through the extreme weakness of the deceased, he could expect a repetition of these fatal poisons would prove a cathartic, and relieve the patient; or that he could mistake convulsion fits, symptomatic of approaching death, for a hypochondriac affection.

"But on considering this point, the court were all of opinion, notwithstanding this ignorance, that if the prisoner acted with an honest intention and expectation of curing the deceased by this treatment, although death, unexpected by him, was the consequence, he was not guilty of manslaughter.

"It is to be exceedingly lamented that people are so easily persuaded to put confidence in these itinerant quacks, and to trust their lives to strangers without knowledge or experience. If this astonishing infatuation should continue, and men are found to yield to the impudent pretensions of ignorant empiricism, there seems to be no adequate remedy by a criminal prosecution, without the interference of the legislature, if the quack, however weak and presumptuous, should prescribe with honest intentions and expectations of relieving his patients."

Gentlemen, such is the law. Samuel Thompson went free, and, for aught we know, in the language

of the story-books, lived happy ever after. The "astounding infatuation" has continued and increased, even, to an extent that attracts hither these reckless adventurers from all parts of the country and from foreign countries, until to-day the city of Boston, in which you sit, is believed to furnish asylum and subsistence to more such than any other community of its size on the face of the earth. They wax fat, and snap their fingers in the face of justice. And in this condition of things we ask you to interfere; not to forbid any citizen from employing any medical adviser whom he chooses to call, but to give us some assurance that when, in time of distress, we invoke the aid of the public practitioner of the healing art, we may not find lurking in his robe a rapacious and ignorant knave.

The argument continues with a very concise and telling exhibition of the inconsistency and absurdity of those who object to the bill as an invasion of individual rights, an interference with personal liberty; states in regard to the ignorant charlatans, against whom the bill is aimed, that the legislature is asked only to require that before these persons shall hold themselves out to the community as practitioners of medicine, not that they shall be as learned, successful, competent, and honest as any other practitioner, but that they shall be of fair repute, and shall have acquired some real knowledge of their art, of the anatomy of the human frame, the position and functions of the various organs of the body, and the nature of disease. When they have done that, the fence is down and the field open; and closes with the following just remarks:—

The bill is not for the physicians; it is for us. The community is overrun with medical mountebanks and impostors, concealing their ignorance and rapacity under high pretensions, and seeking, among the ignorant, the credulous, and the helpless, whom they may devour. The highways and by-ways of our cities are infested with their lurking places, and the public journals are broken out with their advertisements like a plague. The ebb-tide of quackery from our neighbor States is setting back upon us, and the number of these charlatans in our midst increase day by day. We ask you to stay this tide. Perhaps the law will not accomplish all that is hoped for it, but it will accomplish something. To some extent all legislation must fail of its purpose, but some things you can secure. You cannot give the sick man wisdom wherewith to choose his physician; but you can stay the hand which he invokes, unless that hand is guided by enlightened intelligence. You cannot by statute make a good or a learned man; but you can strip the mask from the pretender and the knave. This is the purpose of the bill, and in doing this the people whose interests you have in charge will approve your judgment and uphold your hands.

—The masquerade ball lately given at the New York Academy of Music by the Purim Association, in aid of the Mount Sinai (Jewish) Hospital, netted the very handsome sum of \$18,585.80 for that institution.

MEDICAL PRACTICE ON THE STAGE.

In Boucicault's *How She Loves Him*, which has recently been revived at Wallack's Theatre, New York, there is much over which a medical man may enjoy a hearty laugh, as it contains some very amusing satire on the various "pathies" at present in vogue; though it must be confessed that the regular profession comes in for a good-natured rap or two also. The scene is principally laid in the vicinity of the "United Pautopathic Sanatorium (Limited)," at a sea-side resort, and the play is brought to a conclusion in that remarkable institution, where the hero of the piece, delightfully enacted by Mr. Wallack, feigns to be "in the last stage of an unknown disorder," in order to secure a reconciliation with his wife, from whom he has been separated on account of a misunderstanding. This fearful disease, he tells his better half, when she finally comes to visit him in his last hours, is called "pluribus-sternum-elephantorum;" but it is very well characterized by Diogenes, a sharp-tongued but very faithful old Irish servant (a character which is assumed with distinguished success by Mr. Boucicault himself), as "wife-on-the-brain." In one of the earlier scenes, the husband says to a friend, "Give me your candid opinion on my personal appearance." "You look as if you had taken something which had disagreed with you," he replies. "That's it,—I took a wife. Study me; I deserve to be exposed in a bottle at an anatomical museum, labeled, 'Practical result of six months' steady matrimony on an able-bodied subject.'" The healing art is represented by "Sir Jericho Maximum," of the regular profession, "Dr. Minimum," homœopath, "Dr. Skwertz," hydropath, and "Dr. Sparks," electropath; and one of the most laughable scenes of the play is an absurd consultation between these various medical lights. During the course of this, one of them asks, "Ought we not to support nature?" "Oh, no," replies Sir Jericho (a character designed to hit off some of the peculiarities of the great London practitioners), "our business is to support the apothecaries." The different treatment advised by each is thus concisely described by the patient: "Down with him," says Sir Jericho Maximum; "Up with him," says Dr. Minimum; "Drown him," says Dr. Skwertz; "Blast him," says Dr. Sparks.

The first to visit him is Dr. Minimum, who, after taking the pulse, remarks, "Finding that there is no fever present, I shall be obliged to make some fever, and will therefore exhibit aconite and belladonna, with a little pulsatilla, which will, no doubt, do the work. Put three drops of this phial in a pint of water, and take a teaspoonful every Wednesday night. You must have faith, you see, my dear sir: and faith, by the way, is the only remedy which we of the homœopathic persuasion ever prescribe in allopathic doses."

On hearing of his serious illness, the wife asks if he is really in danger. "Danger!" is the reply, "I should say that he was in the greatest possible danger. Why, there are *four doctors* with him at this very moment." To give her an idea of his alarm-

ing condition, the patient says to her, when she reaches his bedside, "I am a shell filled with the most explosive materials, and liable to collapse at any moment. All the doctors say that my fuse is very short." Notwithstanding the apparent hopelessness of the case, however, he makes a complete recovery in the most extraordinarily short time, much to the astonishment of the four M.D.'s, and the curtain falls upon a happy reconciliation, brought about by means of the ruse adopted and so entertainingly carried out.

MEDICAL NOTES.

—The *Medical Press and Circular*, in an editorial on Pathological Fog, says the recent fogs of London have worked much harm. "Bronchitis, emphysema, laryngeal affections, and a long train of kindred evils have received an impetus which will be felt for years to come. Many an invalid of the next decennium will have to date his invalidism from January or February, 1880."

—We clip the following from the *Ohio Medical Recorder*: "Dr. J. P. Thomas, of Pembroke, Ky., publishes in the *Philadelphia Reporter* a remarkable case of opium poisoning. An infant, three days old, was given by mistake one third of a grain of morphine. The doctor saw the case three hours after, but could not induce vomiting. The patient could not swallow; the sphincter ani was so relaxed that injections were useless, and the doctor's hypodermic syringe was broken. The infant was wrapped in cloths wrung out of hot coffee. Seven hours after taking the morphia, respiration entirely ceased. Artificial respiration was resorted to, after which voluntary respirations continued for some time, only again to cease and again to be established artificially. This was kept up for over forty-eight hours, and ended in the recovery of the patient. The doctor is to be congratulated on his success, and the family on having such a doctor."

—Dr. Kerr (*British Medical Journal*) gave five minims of nitrite of amyl by inhalation in a grave case of uterine hemorrhage. The flow ceased at once and permanently, and the patient was restored from a state of collapse. Dr. Wm. F. Jenks, of Philadelphia, administered ore-drop doses of the nitrite in puerperal eclampsia, and found it almost instantly arrested the paroxysms. He gave it at the approach of a convulsion. Contrary to Kerr, however, he found that its use was followed by extreme hemorrhage and a general relaxation of a previously contracted uterus. Nevertheless, we believe, if the uterus be protected by ergot and ice, that the nitrite of amyl would prove a most desirable and efficacious weapon against eclampsia.

—Before the Société de Médecine of Paris, Dr. Mercier recently demonstrated an easy and practical means of disposing of small vesical calculi. It consists in making the patient lie on his belly; the calculi then fall by their own weight into the anterior portion of the bladder. The patient is now directed to

rise slowly to his hands and knees. In this position he micturates, and the calculi, which have not yet had time to return into the cul-de-sac behind the prostate, are carried away in the stream of urine.

—The *Obstetric Gazette* says that "Dr. Levy, of Munich, gives the results of microscopic examinations as to the condition of the spermatozoa at different intervals after coitus in the case of sixty women who were under treatment for sterility. In fifty-seven out of the sixty, catarrh of the uterus was present. In all these cases only a small number of spermatozoa could be detected within the uterus, and they had all become motionless after the interval, at the outside, of five hours after coitus. In healthy women, on the other hand, the author found that the movements of the spermatozoa within the uterus continued for at least twenty-six hours. Thus the important effect of an altered character of the uterine secretion, in its destructive influence upon the spermatozoa, is demonstrated. Levy believes that when the secretion is healthy the spermatozoa can make their way into the uterus in spite of flexions or stenosis. He draws the inference, with respect to the use of tents or mechanical dilators for the cure of sterility, that, since these measures are liable to set up uterine catarrh, anti-catarrhal remedies must afterwards be used if the dilatation is to have any effect in promoting conception."

—Says the *Medical Record*, "Owing in part to dissatisfaction at the management of the London University, it is said that efforts are being made to establish a university in London which shall take in all the medical schools under its general jurisdiction."

—"Dr. F. Powers, of Westport, Connecticut, says that a woman about sixty years old entered a drug-store in the town, a short time ago, and called for forty-five grains of morphine. The druggist weighed it out. She then called for a glass of water, put the drug in it, and swallowed the whole. The anxiety of the druggist was somewhat relieved by her saying that she had taken morphine for forty years, and that forty-five grains was now her regular dose."

—We learn from the *Harvard Register* that the statement going the rounds of the papers to the effect that one half of the students of Harvard are suffering from disorders of the heart, as the result of smoking and coffee-drinking, is utterly false, and has no foundation whatever. Out of several hundred students critically examined by Dr. Sargent, only two have been found who were suffering to any serious extent from heart troubles.

—The Boylston Medical Society recently awarded for essays first and second prizes as follows: The first prize to C. B. Witherell; subject, *Etiology of Fever*. Second prize to Charles F. Withington; subject, *The Pupil as a Therapeutic Guide*. Both essays were said to be of unusual merit.

NEW YORK.

—Dr. B. F. Dawson has been appointed one of the assistant surgeons to the Woman's Hospital, in the place of Dr. A. A. Smith, resigned.

—"The committee appointed to examine into the advisability of a transfer of the library of the New York Medico-Legal Society to the Academy of Medicine reported favorably at the January meeting of the society. Action was postponed, however, for a month. The library is the largest but two of its kind in this country."

—Dr. Edward R. Hunt, of Albany, a prominent physician of the State, died suddenly at Stamford, Conn., on the 14th of March, in the thirty-eighth year of his age. In 1875 he was secretary of the state society, and the same year was elected professor of diseases of the nervous system in the Albany Medical College. He was the translator of Burchard's Secondary Degenerations of the Spinal Cord, which appeared in 1869, and he published papers on Trichina Spiralis, The Pulse of the Insane, and Hematoma Auris, as well as numerous other contributions to periodical medical literature. At the time of his death he was visiting physician to St. Peter's Hospital at Albany and the Albany Hospital, and special pathologist to the State Lunatic Asylum at Utica.

—The body of Dr. Samuel Hahn, a Jewish physician of this city, who died of erysipelas, was lately cremated in the Le Moyne furnace, at Washington, Pa. He was born in 1841, in Germany, where he studied medicine, and came to New York in 1869; since which time he had built up a successful practice among the German population. Three years ago, when cremation began to be widely discussed here, he became interested in the subject, and ever since then has entertained the wish that his body should be disposed of in this way after death. He advocated the practice on philosophic and hygienic grounds, and he was strongly in favor of the organization of a cremation society, which was contemplated at the time mentioned.

PHILADELPHIA.

—The one hundred and fourteenth annual commencement of the medical department of the University of Pennsylvania was held March 15th; graduates in medicine, one hundred and eleven; in dentistry, twenty; total, one hundred and thirty-one. Professor Harrison Allen delivered the valedictory.

—The commencement exercises of our medical schools are generally held upon succeeding days at the Academy of Music. The fifty-fourth annual commencement of the Jefferson Medical College was held at noon on Saturday, March 13, 1880, when one hundred and ninety-six students were graduated as doctors of medicine. By a coincidence rarely noticed in college annals, the number of graduates was precisely the same as at the last commencement, and also the one preceding. Professor Rodgers delivered the valedictory address, which was well received. The Henry C. Lea prize of one hundred dollars for the best thesis was awarded to Dr. Robert P. Ames, of Massachusetts; the faculty prizes of fifty dollars each for the best original essay upon subjects cognate to the several branches of medicine taught by the respective chairs were awarded to Dr. L. A. Halfey, Pennsylvania, Surgery; Dr. B. M. Yost, Pennsylvania, Phys-

iology; Dr. C. C. Davidson, Pennsylvania, Chemistry; Dr. J. C. Hubbard, Massachusetts, Theory and Practice of Medicine. To Norris Cameron, of Pennsylvania, was presented a case of clinical instruments by Professor Bartholow for the best examination in materia medica and therapeutics. Gold medals for clinical reports of lectures at the Pennsylvania Hospital were given by Drs. R. J. Levis and Thomas J. Morton. Dr. Gardette, president of the board, conferred the degrees upon the graduates, and announced that at a meeting of the board of trustees of the college, held on the day preceding the commencement, Dr. William Thomson had been elected honorary professor of ophthalmology. In virtue of the fact that the Jefferson College possesses a university charter, the degree of doctor of divinity was conferred upon Rev. John Andrews Harris, rector of St. Paul's P. E. Church at Chestnut Hill, and Rev. Edward P. Cowan, in charge of the Market Square Presbyterian Church, Germantown, Penn.

—The American Philosophical Society held its centennial anniversary on Monday, March 15, 1880. It was celebrated by a grand banquet at the St. George Hotel, in Philadelphia, to which our principal citizens were invited. Professors Gross, Da Costa, and many others were also present. This meeting was a memorable one, not only on account of the high standing of the society, which was founded in 1780, but also of the social position of the members and their invited guests. The addresses were published in full in our daily papers, which fully appreciated and did full justice to the importance of the occasion and the brilliant character of the assembly.

—At the close of the banquet Professor Gross started for a short visit to New Orleans, where he will be the guest of Prof. T. G. Richardson. In addition to the many honors that have crowded thick upon him, Professor Gross has just been elected president of the board of trustees of the Pennsylvania College of Dental Surgery of Philadelphia.

—The following very significant and important resolutions were offered by Professor Rand at the alumni meeting, and referred to the executive committee:—

"*Whereas*, Some graduates of the Jefferson Medical College have disgraced not only themselves, but indirectly the college, by openly violating the plainest principles of the ethics of the profession,—notably, by advertising, by the manufacture and sale of secret preparations, and by the practice of exclusive systems; and,

"*Whereas*, The college has no power to withdraw a degree once granted; therefore, be it

"*Resolved*, That the president of the alumni association of the Jefferson Medical College be and is hereby authorized to appoint a committee of three members of not less than five years' standing to act in conjunction with the officers of this society. The duty of this committee shall be to report to this association at its annual meeting such cases of irregular practice as may exist among its members.

"*Resolved*, That to avoid personal controversies no case shall be considered where the accused is a mem-

ber in good standing of a county or district medical association which includes among its officers a board of censors. Moreover, that no one shall be reported by said committee without due notice of the action proposed to be taken, and without an opportunity to be heard in his own defense.

"Resolved, That the recording secretary be requested to keep a book in which each graduate receiving a certificate of membership shall sign an agreement to return the same, in the event of his expulsion by a vote of two thirds of the members present at any annual meeting, under the conditions set forth in the foregoing resolutions."

— While noticing college matters we should not overlook the fact that the alumni of Harvard University residing in Philadelphia sat down to their annual dinner, March 11th, at the Merchant's Club, about forty of the graduates being present. Isaac W. Hinckley, president of the Philadelphia, Wilmington, and Baltimore Railroad Company, was chosen president for the ensuing year, and occupied the chair, Samuel M. Felton, his classmate and the retiring president, filling the place of honor on his right. It was the largest gathering of the alumni that has ever occurred in this city.

— Dr. James King, ex-Surgeon-General of Pennsylvania, died of apoplexy at his home in Pittsburgh, on March 11, 1880. He was in his sixty-fifth year, and was one of the most prominent physicians in the western part of this State. He was a member of the American Medical Association, and attended the meeting in Atlanta last year as a delegate from the Allegheny County Medical Society.

Miscellany.

ELEPHANT BREEDING.

A BABY ELEPHANT BORN IN PHILADELPHIA.

MR. EDITOR, — The birth of an elephant calf away from India is a very rare event; indeed, the impression generally prevails that elephants will not breed in captivity, and until recently no well-authenticated case could be cited to disprove this assertion. The members of the Academy of Natural Sciences and the physicians of Philadelphia have lately been favored with an opportunity of witnessing an exceptional case, and of recording some very interesting facts in regard to elephant breeding and the social habits of this relic of a former age. Professor Leidy, of the University of Pennsylvania, and Dr. Chapman, of the Jefferson College, have especially interested themselves in the case, and have made several examinations of the elephant cow during gestation. From their reports we obtain the following facts: —

The elephant Hebe, on the 25th of May, 1878, was twice covered by a male elephant, a performing member of the same troupe of animals, both now in possession of Cooper and Bailey's London Circus, wintering at Philadelphia. In the act of copulation no peculiarity was observed by the attendants that would distinguish elephants from other animals, thus disproving some fallacies that had become current, owing to the defective opportunity for observation.

At the examination held in March, 1879, by Drs. Leidy, Penrose, Allen, Chapman, John H. Brinton, and others, the following observations were made: the two large mammary glands, situated upon the thorax, immediately between the front legs, were observed to be swollen; the nipples were prominent, and the superficial veins were quite marked. Large sebaceous glands were noticed in the roof of the mouth and behind the eyes. The tongue was like that in elephants generally. The tip was not free, but the whole organ was attached to the floor of the mouth, even possessing less motion anteriorly than posteriorly. The elephant's height was shown to be twice the circumference of the sole of its foot; this fact having been learned from the natives of India, who use this lightning method of calculating the size of the animal from its foot-prints.

The little elephant was born on March 10, 1880, making the entire period of gestation six hundred and fifty-five days, which is beyond the term usually assigned of twenty months. The placenta, which was zonal, was presented to the Academy of Natural Sciences; a dried preparation of it will probably be made by Dr. Chapman. The mother, Hebe, is about eighteen to twenty years of age, and weighs eight thousand pounds.

When the birth took place no obstetrician was present, although several had offered their services. It occurred at night, as usual, about 2.30 A. M. The night watchman gave the following graphic account: When the calf was born, the six other elephants chained upon the same platform threw up their trunks, and, dancing around as far as their chains would let them, set up a trumpeting that produced a scene of wild excitement, and made the mother frantic. She picked up the calf with her trunk and threw it across the stable, a distance of about twenty yards; then breaking her chains she started after the little one, tearing down the railing and demolishing a stove-pipe in her course. The keeper now came in, and under his direction the huge animal became quiet and was again secured, and has remained docile ever since. The new arrival is a female, weighing at birth two hundred and thirteen and one half pounds, thirty-five inches in height, four feet six inches long, and around the body (girth) three feet eleven inches. After the mother threw her, the baby picked herself up and went toddling around the room, and when the excitement was subdued she was led back to her mother, who received her with many caresses. The baby was named America, and promises to be a great attraction. In nursing, its mouth is brought to the breast; it does not suck through its proboscis, as was formerly believed to be the custom of these animals.

Altogether, this event is one of the most interesting that has occurred for a long time, as it is without parallel in zoological annals in this country. W.

"SEA-SIDE ETHICS."

MR. EDITOR, — An article under the above head was published in the JOURNAL of March 14th; let the following be an answer to the "reply" of March 18th: —

The copy of the case taken from my note-book is essentially true; and the flurry, with verbal quibbles and special pleadings, occasioned by the publication, studiously, and perhaps naturally, avoids the question

at issue. This remains the same as before the "reply." The "treatment" of the case and "advice" at the seashore may have been right or wrong,—that is not the point. The following-up the case after the patient went home and came under the care of the regular attendant, still retained in service, and the secret, or confidential correspondence as it is now called,—a correspondence not revealed to this attendant till about a year and a half afterwards,—that is the ethical error. It is hardly the thing to affirm that the printed letters were in reply to the patient's, since every one concludes with a request to "hear again in a week." (JOURNAL, page 236.) Even if the patient sees no professional irregularity in this, the practitioner, accidentally called in, cannot avoid seeing it. And, by the way, how can a patient expect to be properly treated by any physician while at the same time in secret correspondence with another, and partly under his directions? For the patient's good, the true end of all medical practice, such proceedings should be put a stop to.

Again, it matters not whether the correspondence was "asked" for or not; it could not have been asked for until its existence had been revealed. It fell into the attendant's hands, or "was handed" to him, if that phrase is preferred, exactly as described (JOURNAL, page 237), all the letters bearing dates after July 1, 1878. "To contradict¹ this statement" therefore is, to say the least, a little hasty. The matter of volunteering is like unto this also. The letters and the directions bear internal evidence of it. The expression "of his own accord" was once or more made use of by the patient or his family. And so with other quibbles, not worth while to waste time on.

The letters and statement were taken for *professional* purposes; primarily to fill out a record of the case for a professional report, should it subsequently prove worth while. They were received without reservation or restriction, or intimation to hold them private,—quite the contrary, it appeared to the recipient. Indeed, such letters should not be considered private by anybody; the profession has a right to know of such professional acts of its members. A copy allowed for the JOURNAL was for *strictly professional* purposes, without names, on the suggestion that what the letters showed would put vacational attendants at summer resorts on their guard, and would prevent practices said to be too frequent there. The responsibility might be divided or shifted to other shoulders, but there is no desire to do that. A professional-public purpose, not a private end, was the only object in view.

It is said—with what foundation others can better tell—that professional forging at summer resorts is attended with many unpleasant results. The neighboring resident physicians are, to a greater degree than desired, deprived of employment they are will-

ing and abundantly able to undertake; and the relations between them and their own resident patients are too frequently disturbed by the assumptions of temporary practitioners. The temporary practitioner does "not seek the case" of a visitor, perhaps, but after attending such a patient, who would never have employed him but for the emergency, may follow him up with attentions, more or less private, which render the regular attendant's position very embarrassing. The regular attendant will be held responsible to the patient, the members of his family, friends, near or distant, and to business associates, for a continued cognizance of every change in the case, an unerring diagnosis, and a sure prognosis,—this, too, while not unfrequently visiting the household, and consulted by the patient himself, so far as a secret correspondence with another physician, "not seen" by him, will permit.

It is ceded on all hands that a patient has the right to go from one doctor to another, as from one tradesman to another, whenever and as often as he pleases; but practices "considered honorable in business cannot exist between physicians without diminishing their usefulness,"² and the patient is the chief sufferer in such cases. So, also, the patient has a right to change his regular attendant at pleasure, but no physician having the good of the patient solely at heart will intrude advice, or permit himself to treat another's patient, without a full understanding with the attendant. Moreover, the regular attendant has a right to be relieved from all responsibility, which he was not in this case, during such a method of treatment.

To those who know the parties the motive assigned (JOURNAL, page 284, second column) is too ridiculously absurd to require a word; to others this allusion to it must be its sufficient refutation. The hasty statements, erroneous or ill founded, and the unnecessary detraction indulged in in the "reply" may be left without further comment.

B. E. COTTING.

ROXBURY, March 19, 1880.

MR. EDITOR.—I merely wish to quote an extract from a letter of Mr. Rice to me, dated July 3, 1878, to which my first letter was the reply. A few days before the 3d, he had had severe pain, which Dr. Cotting, who was called in, relieved by a subcutaneous injection of morphine. Mr. Rice wrote as follows: "The next morning he [Dr. Cotting] called to see me, took the temperature of my body, and conversed with me about your call, and I showed him your prescriptions, etc. He said that he was very glad to know that I was under your charge; that he knew you well, and would write to you."

It seems to me, therefore, that I was justified in my subsequent letters and course. As this shows that Dr. Cotting was aware within a few days that the patient had been treated by me, it would have been in much better taste, if he felt aggrieved then or at any later time, had he allowed an opportunity for personal explanation, instead of blindly rushing into print.

HALL CURTIS.

[We inserted the original correspondence to illustrate a delicate point in ethics without knowing at whom it was directed. Now that it has assumed so personal a character we must close the discussion.—Ed.]

¹ JOURNAL, page 283, last section. To repeat, the correspondence was not seen by the attendant until January, 1880, as stated. It could not have been shown July 1, 1878, as all the letters were written after that date. So much for that "contradiction." The rest are like unto it, as well as other and various charges; and if not specifically refuted it is simply for want of time and space, and because they sufficiently refute themselves.

All know how easily sometimes a patient seems to forget the anxious solicitude and devoted care of a faithful attendant, but here is an instance of unnatural readiness to assist in vilifying an old friend in order to sustain a professional irregularity, the detrimental nature of which a non-professional man cannot form any true estimate of whatever. The false issues attempted in this patient's letters are evidently the promptings of another, whose directing influence is conspicuous throughout. It is not the sin, but its exposure, that some men rail about.

² New Code of Ethics, Massachusetts Medical Society, Chapter IV. Compare Twitchell, Transactions New Hampshire Medical Society, 1879, page 87.

REPORTED MORTALITY FOR THE WEEK ENDING MARCH 13, 1880.

Two thousand one hundred and nine deaths were reported; 734 under five years of age; principal "zymotic" diseases (small-pox, measles, diphtheria and croup, diarrheal diseases, whooping-cough, erysipelas, and fevers) 377, consumption 383, lung diseases 332, diphtheria and croup 140, measles 55, scarlet fever 48, whooping-cough 37, typhoid fever 34, diarrheal diseases 26, erysipelas 16, malarial fevers 13, cerebro-spinal meningitis eight, small-pox none. In addition, Cleveland reports lung diseases 12, scarlet fever seven, diphtheria and croup five, consumption three, malarial fevers and whooping-cough one each, — total deaths not given; and Milwaukee reports diphtheria and croup nine, lung diseases four, consumption three, cerebro-spinal meningitis two, scarlet fever and diarrheal diseases one each, — total deaths not given. From *measles*, New York 27, Philadelphia 10, Brooklyn eight, Chicago five, Pittsburgh two, Buffalo, New Haven, and Lowell one. From *whooping-cough*, New York eight, Brooklyn and Pittsburgh four, Philadelphia, Chicago, and Boston three, New Orleans, Buffalo, Charleston, and Palmer two, Baltimore, Cincinnati, New Haven, and Gloucester one. From *erysipelas*, New York nine, Brooklyn two, Chicago, Cincinnati, New Orleans, Buffalo, and Fall River one. From *malarial fevers*, New York six, Brooklyn three, New Orleans two, Chicago and Nashville one. From *cerebro-spinal meningitis*, New York and Philadelphia three, Worcester and Holyoke one. Two hundred and three cases of measles, 41 of diphtheria, 29 of scarlet fever, three of whooping-cough, and one of typhoid fever were reported in Brooklyn; diphtheria 28, scarlet fever 13, in Boston; diphtheria 22, scarlet fever one, in Milwaukee; scarlet fever 35, diphtheria 15, typhoid fever one, chicken-pox one, in Providence; diphtheria three, scarlet fever one, in Cambridge; diphtheria four, scarlet fever two, in New Bedford. The death-rate of whites in District of Columbia was 18.7, of colored 39.0.

The total number of deaths, and of deaths under five, reported was somewhat less than for the previous week. Lung diseases and diphtheria caused fewer deaths, while the decrease

from scarlet fever was very great. Measles showed a greater mortality. In 36 cities and towns of Massachusetts, with an estimated population of 1,003,160 (population of the State about 1,690,000), the total death-rate was 19.47 against 22.47 and 21.26 of the previous two weeks, with an increased fatality from scarlet fever, whooping-cough, and typhoid fever.

For the week ending February 21st, in 144 German cities and towns, with an estimated population of 7,614,683, the death-rate was 27.4 against 27.5 and 26.9 of the previous two weeks. Four thousand and eighteen deaths were reported; 1782 under five: pulmonary consumption and acute diseases of the respiratory organs each 606, diphtheria and croup 160, whooping-cough 72, typhoid fever 66, scarlet fever 62, measles and *roteln* 29, puerperal fever 21, small-pox (Thorn, Benthien, and Dresden) three, typhus fever one. The death-rates ranged from 20.4 in Wiesbaden to 42.3 in Nuremberg; Königsberg 33.9; Dantzic 32.8; Breslau 29.6; Munich 35.1; Dresden 26.0; Berlin 24.8; Leipzig 21.4; Hamburg 30.5; Hanover 22.3; Bremen 22.8; Cologne 28.3; Frankfurt 26.8. For the same week, Vienna 31.4; Paris 36, — small-pox, diphtheria, and typhoid fever continuing very prevalent.

For the week ending February 28th, in the 20 English cities with an estimated population of 7,499,468, the death-rate was 23.1 against 26.0 and 31.0 of the previous two weeks. Three thousand three hundred and twenty-two deaths were reported. Lung diseases declined to 459 from 1557, 1020, and 693 of the previous three weeks; whooping-cough 186, scarlet fever 118, measles 80, diarrheal 29, fever 26, diphtheria 15, small-pox (London) 13. The death-rates ranged from 14.4 in Wolverhampton to 32.0 in Plymouth; London 23.7; Brighton 19.0; Bristol 19.3; Birmingham 20.5; Liverpool 27.0; Manchester 24.3. In Edinburgh 21, Glasgow 21, Dublin 42 (three deaths from small-pox).

The meteorological record for the week in Boston was as follows: —

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U. S. ARMY, FROM MARCH 13, 1880, TO MARCH 19, 1880.

WHITE, R. H., captain and assistant surgeon. Granted leave of absence for six months, with permission to go beyond sea. S. O. 55, A. G. O., March 11, 1880.

FINLEY, J. A., captain and assistant surgeon. Assigned to duty at Fort Adams, R. I. S. O. 41, Department of the East, March 15, 1880.

STOLAN, WILLIAM J., colonel and surgeon, medical director, Department of Dakota, died at St. Paul, Minn., March 17, 1880.

SUFFOLK DISTRICT MEDICAL SOCIETY. — A regular meeting will be held at the hall, No. 19 Baylston Place, on Saturday evening, March 27th, at seven and a half o'clock. The following papers will be read: Dr. J. B. Ayer, A Severe Case of Scarlet Fever. Dr. B. Joy Jeffries, Control of Color-Blindness and Visual Defects in the United States. Disputant, Dr. O. F. Wadsworth. All members of the Massachusetts Medical Society are cordially invited to be present and to take part in the discussion. Supper at nine o'clock.

T. M. ROTCH, M. D., Secretary.

Lectures.

CLINICAL LECTURES ON ORTHOPÆDIC SURGERY.¹

DELIVERED AT BELLEVUE HOSPITAL.

BY LEWIS A. SAYRE, M. D.,

Professor of Orthopædic Surgery and Clinical Surgery in Bellevue Hospital Medical College.

III. PARTIAL PARALYSIS AND WANT OF COORDINATION FROM IRRITATION OF THE GENITAL ORGANS.

GENTLEMEN, — To-day I bring before you again the little boy whom you saw at the lecture last Saturday, in order to make some further remarks in regard to the case, and to perform a small operation upon him in your presence. The child, you will remember, was supposed to be suffering from disease of the knee-joint, and for a considerable time past had been wearing the instrument which I then removed from the limb. This consisted of two iron bars, which were joined posteriorly and fastened by means of a swivel, in such a way that the apparatus was movable at both the upper and lower extremities. Now it is utterly impossible to confine the knee by any such arrangement as this, and if there had been any disease of the joint present the instrument would have been entirely useless so far as preventing motion and keeping up extension were concerned. As these are the two essential points in the treatment of disease of the knee-joint, you can readily imagine how very serviceable an affair of this kind would be in that affection.

But in the present instance, when I came to make an examination of the knee, I found that there was absolutely no disease of the joint whatever at that time, and it seemed altogether probable that there never had been. At all events, if there had been, the cure was a remarkably perfect one, as there was not the slightest trace of any results of the inflammatory action remaining. The real trouble about the knee, I discovered, consisted in a loss of power in the quadriceps femoris muscle, and this had probably been mistaken for disease of the joint from the first; since, as I said, it was certainly questionable whether any such disease had ever existed. We have, then, a paralyzed limb instead of an inflammatory, diseased knee-joint to deal with. On Saturday I placed strips of perforated tin about the knee, after the manner of Dr. Fühler, in order to prevent any motion in the joint, and immediately the child was able to walk. Since then the house-surgeon has further secured the part by means of a plaster-of-Paris bandage. Although this little fellow is two and a half years old, his mother tells me that he has never been able to walk, or even to stand alone, before.

The improvement thus caused is certainly very gratifying; but you must bear in mind that such treatment is only palliative, as the underlying cause of the paralysis still remains. This, you will recall, we found to exist in all probability from the condition of the penis, in which there was phimosis with adherent prepuce. As a result of this there is, in addition to the paralysis, constant priapism, great irritability of the bladder, causing a frequent desire to urinate, and terrifying dreams, as well as incessant restlessness during the hours of sleep. By making an artificial anchylosis of

the knee-joint we have succeeded in giving the child power to walk; but this does not restore life to the quadriceps muscle, and does not do away with the troublesome symptoms just mentioned,—in short, as I have said, it does not reach the real origin of all the difficulty here. The trouble will unquestionably continue as long as the source of irritation is allowed to remain untouched.

This subject of irritation of the genital organs and the very serious results that are apt to occur in connection with it is not, I am sorry to say, appreciated by the profession at large to the extent that it should be; though I for one, at least, have done all that I could to direct attention to the matter. It is one of such great importance that you cannot be too constantly on your guard respecting it; the truth of which statement, I think, is well illustrated by the remarkable case which I will now read to you. The notes were kindly taken from the case-book of the Workhouse Hospital on Blackwell's Island, and sent me by Dr. A. R. Mott, Jr., of the Randall's Island Hospital, who was at the time house-physician to the institution where it occurred. "John English, aged forty-six, native of England, widower, clerk by occupation. Admitted to Workhouse Hospital, Blackwell's Island, December 23, 1878. Patient had been at work for a week, as a prisoner. On the 23d he was noticed to be restless and uneasy, and finally in the evening he fell from his bunk in a fit. During the next forty-eight hours he had several convulsions (eight or nine altogether), and in the intervals between them lay in a semi-comatose condition, showing no consciousness except to stir a limb when pinched. Pulse 120, temperature 101.5° F., respiration 18. Swallowed nothing, and passed feces in bed. He continued in this state until the evening of December 25th (the temperature in the mean while having fallen to 100° F.), when a string was discovered passed twice around the penis just behind the corona and tied, the long prepuce serving to conceal it from notice. While this was not sufficiently tight to cause occlusion of the urethral canal, it had given rise to the formation of a firm, indurated band, which did not altogether disappear for four or five days after the string had been removed. Within one hour from the removal of the latter the man sat up and asked for milk, and from this time remained perfectly well, being under observation for fully three months. He declared that he remembered nothing that had taken place during the three days previous. This patient had never before been subject to 'fits,' and although he confessed that he was moderately addicted to drink denied venereal, and said that he had led a 'virtuous life' since the death of his wife, two years before."

In children a certain amount of agglutination between the glans penis and the prepuce covering it is normal in early life, while the prepuce gradually unfolds until the age of puberty, when the glans can be uncovered without difficulty. But sometimes, instead of merely an agglutination, there is actual adhesion, and, as a result of this, there accumulates behind the corona a ring of hardened smegma, which consists principally of earthy deposits from the urine. This concretion, which is almost as hard as stone, being tightly imprisoned by the narrow prepuce, produces so much irritation that the penis is kept in a constant state of erection, and the entire nervous system of the child becomes profoundly affected. On looking at the

¹ Reported for the JOURNAL.

little fellow now before you, you observe the marked pallor of his countenance, and this is a characteristic feature of all these cases, on account of the constant worryment and strain to which the patient is subjected. When we come to examine the penis we do not wonder that he has a continual desire to pass his water, for even in this state of quiescence we find that the meatus and the surrounding mucous membrane are very red, as though there were urethritis present. When I touch with my finger the orifice of the urethra, you notice that an instant spasm of both lower extremities is produced by the irritation, and hence you can readily see how the constant pressure of the child's clothing will act in keeping up an excitation and a more or less permanent state of erection in the penis. You all know what a powerful impression an ordinary erection, lasting but a few moments, makes upon the whole organism in the adult, and from this you can judge what an enormous strain upon the system must be constantly kept up in the case of a young child where there is such a state of affairs as exists here.

There is but one way to effect a cure in such a case as this, and that is by operating upon the organ where the seat of difficulty lies. In some instances it is sufficient merely to slit up the narrow prepuce, and thus release the glans from its imprisonment; but where there is great redundancy of this part, as in the present patient, it is necessary to remove a considerable portion of it by circumcision. In performing the operation, I first draw the prepuce well forward with the fingers, and grasp it in front of the glans with a pair of flat-bladed forceps made for the purpose, when I snip off cleanly with the scissors all the portion in front of the forceps. I can now readily draw back the integument over the glans, but not the mucous membrane, which has not been reached in the cutting, and so still remains tightly around the part. Should we go no further in our operation than this, we should do our patient more harm than good; and, accordingly, having inserted a grooved director under the mucous membrane, I divide it along the dorsum of the penis for a sufficient distance, and then pull it back from the glans, at the same time breaking up such adhesions as are met with. I have now uncovered the glans, and you observe the ring of hardened smegma which is always found behind the corona in these cases, and, having cleared that all away, I take the glans between the fingers and tear the frenum in two. The head of the penis is therefore at length completely bared. It is sometimes necessary to take a stitch or two between the edges of the skin and mucous membrane, but it is always better to avoid this if possible. By cutting the mucous membrane back to the corona, and thus dividing or tearing the frenum, as you have just seen me do, we are usually able to bring the two edges into close apposition, and sutures are thus rendered unnecessary.

The dressing to be applied after the operation is a simple one. Drawing back the prepuce sufficiently to expose the whole glans, and bringing the edges of the skin and mucous membrane close in contact, I apply a little styptic cotton or persulphate of iron to the torn frenum, and place small strips of old linen rag behind the corona in such a way that the cut edges of the skin and mucous membrane will be retained in their proper position. These should not be tied, but simply laid on loosely, so that if there is any swelling of the parts following the operation the penis will not be

tightly constricted and its circulation interfered with. They should then be allowed to remain in position, the blood drying in them, until they fall off of themselves, when, if all goes well, it will be found that the parts have all perfectly healed, and the operation has been a complete success. I next place, externally, a little more styptic cotton, so as to assist in coagulating the blood without interfering with primary adhesion between the cut edges, which is sometimes the case if it is applied directly to the raw surface. In order to protect the exposed glans from friction by the clothing or other pressure, we put a handkerchief or piece of cotton batting, twisted somewhat into the shape of a ring, around the penis, and lay a linen cloth wet with cold water (which can be renewed as often as is desired without disturbing the rest of the dressing) just over the glans. Finally, an ordinary diaper is pinned on, in order to keep the whole in position.

If the mother will be kind enough to bring this child back at the end of a fortnight, I am sure that even in that short time we shall find a marked improvement in the case. In the mean while I can, from a very large experience with similar cases, prophesy with confidence that the little patient will sleep quietly from the very first night, and be no more troubled with any nightmares; and if it should turn out that what we have now done for him should be the means of restoring function to his paralyzed muscles, it will certainly be a very extraordinary way of curing "chronic disease of the knee-joint."

In connection with this case I will refer briefly to another, of similar character as regards the origin of the trouble present, though somewhat different in its manifestations, which, as many of you will no doubt recall, was at the clinic a few weeks ago, and which I mention now because it presented some points of more than ordinary interest. The patient, you remember, was the child of a physician, residing at a distance, and was brought here by the father himself. This was the second occasion on which the latter had consulted me in reference to him: the first time having been more than six months before, in April last. At that time he was four years of age, and had never been able to walk. He could not even stand without assistance, and then his legs were always more or less flexed, as it was impossible for him to straighten them out when any weight was resting upon them. He was large and fat, but his flesh was flabby, and he presented the same pale and waxy appearance that the child just operated upon does, while he lacked to a very marked degree the power of controlling his muscles. This was especially the case as regards those of the tongue; so that when he attempted to talk he always stammered badly. Nevertheless he was quite as intelligent and quick-witted as any child of his age, and, as evinced by the expression of his countenance, comprehended perfectly everything that was said to him, though he was, unfortunately, unable to reply. He never rested well when asleep, and frequently seemed to suffer from nightmare. Moreover, it was ascertained that he had almost constant priapism, and that there was a continual dribbling of urine from the penis, while he was unable to eject a full stream in the right direction.

On making an examination of the genitals, I found that it was impossible to uncover the glans, as the prepuce was narrow and firmly adherent, just as in the case of to-day. From previous experience, therefore, I felt justified in concluding at once that here was the

source of all the reflex irritation present, and advised in the strongest terms that the doctor should have him circumcised. Accordingly, he was taken home, and this was done, as was thought, but, unfortunately, it was performed in such an imperfect manner by the surgeon who attempted it that it resulted in no permanent benefit; for the prepuce was merely slit up along the dorsum of the penis, while the mucous membrane remained intact, and the glans was really never uncovered. Yet immediately after the operation, incomplete as it was, the stammering disappeared, and the child for the first time in its life was able to speak distinctly. The parents were delighted, and on account of the improvement which resulted so quickly they felt assured that their darling would soon be restored to perfect health. But, alas, their hopes were short-lived, and at the end of three months the child was as bad in every respect as he was before. It was on account of this relapse that they came to consult me the second time.

When I examined the penis I found that the prepuce was firmly adherent, as before, and that there was a long projecting piece of integument, which had been left by the operation. You remember that I then in your presence performed circumcision in the proper manner, just as I have done to-day, and as it ought to have been done at first. When the glans was uncovered, the father remarked that it was nearly twice as large as it had been at the time of the first operation, a few months ago; which shows that its regular development had been interfered with by the abnormally narrow and constricted prepuce. Four hours after the operation I called to see the little patient at his hotel, just as the family were on the point of leaving town, and when I entered the room he immediately called out to me, "How do you do, Dr. Sayre?" in the most unhesitating and distinct manner, and you will recollect that just before the operation he could hardly articulate distinctly. Finally, I wish to bring back to your minds to-day still another case, which was here just before the physician's child, and which was of a more aggravated character than either it or the one operated on this morning. This was a boy from Norfolk, Virginia, fourteen years of age, who had been brought to me first nearly two years previously, by Dr. Norcom, of North Carolina. Up to that time he had been supposed to be hopelessly idiotic; while he had never been able to feed himself, to speak an intelligible word, to walk, or even to stand up, so that he required the constant services of a nurse, both by day and night. As I found, however, that he was subject to continual priapism and that the prepuce was constricted and adherent, I believed there was still hope for him, and, accordingly, performed circumcision. Directions having been given for the frequent manipulation of the feeble muscles, and the application of electricity to them, in addition, he was sent home, with the request that he should be brought back to New York about once in six months, so that I could observe the progress in the case. From the first there has been a gradual but altogether satisfactory improvement, and for some time now he has been able to get about very nicely with the assistance of a wheel-crutch; while his faculties seem to have become developed, and he is able to speak with considerable facility. These cases, I think, will be sufficient to convince you of the very great importance of this matter; and if the consideration of them will enable any of you to discover the real

cause of the phenomena presented by patients suffering in this way, and to adopt the proper method of treating them, I will not have talked in vain upon the subject.

THE STUDY OF PSYCHOLOGICAL MEDICINE.

BY WALTER CHANNING, M. D.

DURING the last twenty-five years great progress has been made in the care of the insane. Asylums are more comfortably built and furnished, and the patients are better clothed and fed. This improved condition of affairs is cause for congratulation; we should not however rest here, for not only is there much more work to be done in this direction, but the consideration and study of insanity as a science is still in its infancy. Having made our insane persons comparatively comfortable in material ways, we must next proceed to find out by definite, scientific methods the nature of their disease, as well as its causes and treatment. Among the various methods of acquiring this knowledge I propose in this paper to briefly consider the study of psychological medicine in medical schools and insane hospitals.

In medical schools in this country very little attention has been bestowed on the subject, and in England the system is so imperfect that within the last year a petition has been gotten up by prominent alienists asking that regular systematic instruction should be required in medical colleges.

The custom of giving lectures is becoming more common in America, and this is an encouraging indication, but the importance of the subject is not fully appreciated. The lectures given are good as far as they go, but dwelling only on the forms and direct treatment of insanity they can but very imperfectly accomplish what should be their object. It must be remembered that medical men are in some directions the teachers of their patients, and are in a position to guide and direct, and sometimes to form, the lives of many of them. They see persons at the earliest period of a threatened attack. Now by a correct knowledge of the varied causes of insanity and an appreciation of the great interests at stake in preventing its manifestations, they could wield an immense power in exercising a wholesome moral treatment. There is frequently a time when a threatened attack can be averted, but no one sees the indications of approaching trouble, no moral control is exerted, and the disease goes on developing. If the physician were a student of character, quick in his perceptions and in the habit of looking for and correcting peculiarities of disposition or character, he would at such a time take advantage of an opportunity now often lost. To turn his thoughts in this direction, a systematic course of training in psychology would be of the greatest benefit, and it should be taught as a fundamental branch in medical schools. Particular attention should be given to the metaphysical side of the subject, and our duty to the insane from a moral point of view should not be forgotten. Students should have psychological textbooks, go to compulsory recitations, pass an examination, and leave the medical school with some definite knowledge on the subject. As an important part of this system of instruction would be the frequent visita-

tion of an insane hospital and the clinical study of cases, I hope the time is not far distant when each insane hospital will have a certain number of internes. They can occupy the same position as in general hospitals, and perform much of the drudgery which absorbs the time of assistant physicians. Such a position would attract good men, if made desirable, as it might be, and would do very much toward creating an interest in physicians in the subject of hospital requirements. With the best judgment in the world, men who are practically unacquainted with hospital details cannot accurately comprehend such requirements. A short residence occupied by active work will do more to initiate a man into the peculiar workings of a hospital than years of casual visits. I hold that a judicious system of interne appointment would bring the public and hospital authorities nearer together, and remove the veil from some of the mysteries in which, in consequence of our present system, some of our hospitals are apparently shrouded.

The second subject which I propose to bring briefly under consideration is, as stated above, the study of insanity in insane hospitals. What might be called the medical treatment of insanity is limited; it consists chiefly in meeting conditions as they arise, and applying appropriate remedies. Moral treatment is what is peculiarly demanded, and this necessitates a careful study of each individual case and the bringing to bear of the most varied influences. Medical men are apt to be too overworked to have sufficient time to devote to the patients individually. The medical staffs are all too small, a fact partly due, no doubt, to the moderate amount of medical care required. We find our superintendents, custodians of their patients, immersed in business cares, and with little time for medical duties. The clinical and pathological study of cases they have no opportunity to pursue. That they have the *desire*, according to their individual bent for study, cannot be doubted. For the better understanding of insanity, therefore, our insane hospitals must have larger staffs, thereby allowing the physicians the necessary time, which they now lack. A spirit of enthusiasm and rivalry, even, might eventually be instilled into hospital men. For the study of the pathological development of insanity our medical officers have not yet, as a rule, sufficient education. There is no reason why they should not have in the future the whole charge of this subject, but at present it can best be done by expert brain pathologists. Brain pathology is still in its infancy, unsettled and unreliable. No matter how skeptical we may be as to its definite character, we should not be satisfied until doubt is out of the question. It may be said that on the whole most authorities regard insanity as a disease of the brain, but no one can as yet satisfactorily give the morbid appearances characteristic of its different forms, and there is therefore still a wide field open for original investigation. Now to make examinations of the brain which will be valuable, they should be conducted by a man very familiar, first, with natural brain histology, and, second, with the pathological appearances resulting from all forms of brain diseases. To this knowledge he should add the rare accomplishment of a thoroughly trained microscopist, and have unlimited patience and plenty of time to make examinations which are often laborious and fatiguing. Without this knowledge, without this training, his results may not be absolutely worthless, for all honest labor has a certain value, but as *scientific* results

they will not be reliable, and hence for all practical purposes useless. Anything short of such work can have no real scientific value. Amateur autopsies in insane hospitals are now occasionally reported, but even these are uncommon, and in some cases no microscopic examinations have been made, and the most trivial points have been unduly magnified.

If it were possible, each hospital might have for a certain length of time a special pathologist, who could make systematic examinations, found a pathological cabinet, establish good records, and give the medical officers instruction. In Massachusetts the following plan might be adopted: A man with the necessary high qualifications being found, he could be appointed state pathologist at a good salary for five years. Each of the five years he could live at one of the hospitals, gradually establishing a uniform system of carrying on pathological investigations. His first year could be devoted to one hospital, where he would inaugurate his system. Having established his system in this hospital, the second year he could move to another, retaining general charge of the pathological work in the first hospital. At the end of five years the system would be established on a firm footing, and the pathologist's services might or might not be dispensed with. So much time is now devoted to pathology at medical schools that in the future a knowledge of this subject might be considered a necessity in applying for insane hospital positions.

RECENT PROGRESS IN URINARY SURGERY.

BY T. E. CURTIS, M. D.

POLYURIA ACCOMPANYING AFFECTIONS OF THE BLADDER AND URETHRA.

In certain diseases of the urinary organs which come under the care of the surgeon the amount of urine secreted is liable to be largely increased. The polyuria observed in such cases constitutes an important symptom, which often adds considerably to the sufferings of the patient, and sometimes obscures the diagnosis of the primary disease. It seems, however, to have almost wholly escaped attention, until brought to light by Professor Guyon, of Paris, in his clinical lectures, and more particularly in the essays recently published by two of his pupils, Masson¹ and Jean.²

The diseases in the course of which polyuria is apt to occur are the following: stone in the bladder occasionally causes it; urethral stricture is still more apt to do so; it may also accompany tuberculosis of the prostate and bladder; most frequently, however, by far it results from obstructive hypertrophy of the prostate. The daily total quantity of water passed in such cases is, on an average, about double the normal amount, varying from two to five quarts or more. The urine is sometimes quite clear and colorless, but more often it is whitish and slightly turbid, looking as if a little milk had been added to it. The reaction is neutral or alkaline, and decomposition is apt to take place rapidly after emission, with formation of abundant crystals of triple phosphate. The specific gravity is low, ranging from 1005 to 1010, rarely reaching 1015.

¹ Dr. Noël Masson. De la Polyurie dans quelques Affections chirurgicales des Voies urinaires. Paris, 1878.

² Dr. Alfred Jean. De la Rétention incomplète d'Urine, etc. Paris, 1879.

The excretion of urea is undiminished, the amount contained in the urine of twenty-four hours, namely, about twenty grammes, being as much as would normally be excreted under the existing conditions of invalidism and hospital regimen. In this respect, therefore, there is a great difference between this form of polyuria and that observed in *diabetes insipidus*, for in the latter disease urea is often passed, according to Dickinson, in three or four times the normal quantity. A curious and often troublesome feature is the more abundant secretion of urine by night than by day, wherein this polyuria resembles that attending the form of chronic Bright's disease known as interstitial nephritis or renal cirrhosis. In only one case is the excretion of urine apt to be more abundant in the day-time than at night, namely, in calculus disease of the bladder.

The amounts of urine passed by a patient are liable to vary at different times. The quantity often diminishes and approximates the normal as a result of successful measures of treatment, when the primary disease is such as to admit of cure or alleviation. It also undergoes a marked and sudden diminution coincidently with the on-set of febrile attacks due to inflammatory complications or to operative procedures. Lastly, it grows gradually less and less when a fatal termination is drawing near.

The pathological physiology of polyuria in surgical diseases of the bladder and urethra is still somewhat obscure. In some cases, especially when polyuria results from stricture of long standing, it is doubtless dependent upon the existence of the form of interstitial nephritis known among English surgeons by the name of "surgical kidney." According to Rendu and Jean, this form of renal disease differs from chronic Bright's disease, or renal cirrhosis, in that it is never accompanied by hypertrophy of the heart. Not unfrequently, however, the excessive secretion of urine constitutes a temporary disturbance, which subsides when the primary affection upon which it is dependent is cured or relieved. In such cases the production of the symptom cannot properly be attributed to an incurable renal disease. Polyuria then exists as a functional disturbance of reflex origin, due to a chronic irritation of the bladder or urethra, and falls under the general law, according to which the irritation of the sensitive lining of all excretory channels serves as a reflex stimulant to the secreting gland.

In stricture well-marked polyuria is quite exceptional, occurring in only four out of a hundred cases examined with reference to this point by Masson. It is observed mainly in cases of stricture of long standing, in which the phase of renal complications (surgical kidney) has been reached. In cases of stone in the bladder, also, polyuria is rare; when met with it is apt to be more marked in the day-time than at night, doubtless in consequence of the greater irritation to which the bladder is subjected when the patient is up and moving about. In urinary tuberculosis polyuria occurs intermittently, in temporary paroxysms, as a result of irritation of the neck of the bladder and prostatic urethra.

The most frequent cause of marked polyuria of long duration is obstructive hypertrophy of the prostate, with incomplete retention of urine. According to Jean, who has made a careful and valuable study of all the symptoms resulting from imperfect evacuation of the bladder, an excessive secretion of urine is observed in the majority of such cases. Polyuria sometimes oc-

curs in hypertrophy of the prostate as the initial symptom. An interesting case of this description, in which diabetes insipidus was simulated, was recently recorded in the JOURNAL.¹ More often, however, the excessive secretion of urine is preceded by the dyspeptic disturbances due to imperfect evacuation of the bladder, to which Guyon has called attention (dry, red tongue, thrush, constipation or diarrhoea, anorexia, vomiting, headaches, hemicrania, etc.). The polyuria increases as the case progresses, subsiding spontaneously during febrile attacks, or when the phase of terminal cachexia is reached. When, on the other hand, the irritation kept up by the chronic partial retention of urine is relieved by the artificial evacuation of the bladder by means of the systematic use of the catheter, all the symptoms undergo marked relief, and the undue secretion of urine subsides, or at least is considerably lessened. The most marked examples of polyuria, in which the daily total reaches or exceeds five or six quarts of urine, are observed in patients with distended bladders. When the amount of residual urine is small or moderate the secretion of urine is less abundant. As a consequence of the excessive activity of the kidneys, there is much thirst, and the calls to urinate are very frequent and troublesome, especially at night, when the disturbance is at its maximum. Such being the conditions under which the symptoms just alluded to originate, it is obvious that a prompt resort to the catheter is clearly indicated, both for the purpose of diagnosis and as an efficacious measure of palliative treatment.

THE TREATMENT OF STRICTURE OF THE URETHRA.

Mr. Teevan,² of London, passing in review, for purposes of comparison and selection, the various operations that may be performed in cases of passable stricture, says that they may all be arranged under the following heads: (1.) *Incision*, which includes internal, external, and subcutaneous urethrotomy, and also scarification. (2.) *Laceration*, which embraces the so-called "immediate treatment" of Holt, the "division" of Voilemier, splitting, rupture, and over-distention when carried beyond the limits of true dilatation. The object of these various procedures is to enlarge the calibre of the urethra at the narrowed points, so that it shall be equal to, at least be not much less than, that of the healthy portions. The result aimed at is the addition or insertion of a "ciatricial splice," which shall as much as possible resemble the normal tissue. Pathology teaches us, however, that cicatrices tend to contract in varying degrees, those resulting from lacerations being more retractile than those which follow clean cuts. Therefore, if a stricture be divided by longitudinal incision, a soft, supple cicatrix will ensue, oval in shape, and having its long axis parallel with that of the urethra. If, however, the stricture be torn through, an irregular cicatrix will be formed, more or less obliquely crossing the canal, and not having its axis parallel to that of the urethra. Another consideration which leads Mr. Teevan to express a decided preference for internal urethrotomy, as compared with the various lacerating or splitting procedures, is the greater safety of the treatment by incision. "The most important fact which should influence us in selecting a cutting operation rather than a lacerating one is

¹ See the JOURNAL, November 27, 1879, page 770.

² W. F. Teevan. Lettsomian Lectures on the Treatment of Stricture, etc., with Special Reference to Recent Progress. The Lancet, February 28, 1880, page 418.

that the mortality attending the so-called immediate treatment is much greater than that which attaches to internal urethrotomy. A large number of deaths have occurred in this country after the former method which have never been published, and no surgeon has as yet gathered the statistics of even three hundred cases. From inquiries I have made into the statistics of upwards of one thousand cases of internal urethrotomy, I find that the mortality attached to it may be reckoned at from one to three per cent, in skillful hands. Mastin, of Mobile, has performed the operation three hundred and thirty-three times without a death. In Paris, Guyon has operated on two hundred and fifty patients, with seven deaths. Mallez has had one hundred and eighty-two cases, with two deaths. I have performed the operation fifty-three times in all, and have never had a death. The relative risks attached to cutting and laceration were well seen at the Roosevelt Hospital, New York, where the so-called immediate treatment proved doubly as fatal as internal urethrotomy. Therefore, from all that I have indicated, it is clear that a cutting operation ought to be selected for stricture. . . . Internal urethrotomy, therefore, remains as the stock operation for stricture."

PRÆPERITONEAL CELLULITIS.

This name has been applied to a phlegmonous inflammation of the loose areolar tissue occupying the *præperitoneal space of Retzius*. The latter, situated in the hypogastric region of the abdominal wall, between the posterior surfaces of the recti muscles and the suprapubic parietal peritoneum, is a virtual space or cavity, which is destined to be filled by the bladder, when the latter, becoming fully distended, rises from its situation in the pelvic cavity behind the pubic symphysis into the abdomen. In this locality, above the pubic arch and the empty bladder, between the muscular layer of the abdominal wall situated in front and the parietal layer of the peritoneum situated behind, a circumscribed cellulitis or phlegmon sometimes occurs, presenting clinical features which are of interest to the urinary surgeon. This affection has recently been made the subject of several publications,¹ of which we present a synopsis.

The circumstances under which perivesical cellulitis develops itself are various. Guyon distinguishes three forms of the affection. One, which he calls a pericystitis, occurs chiefly in old men, as a sequel of inveterate cystitis. Another form results from the extension of a phlegmonous prostatitis, invading the pelvic cellular tissue. The third form, constituting the true *prævesical phlegmon* of Guyon, originates independently of any disease of the urinary organs. Its causes are generally obscure; it is occasionally observed in connection with diseases of the bowels. The affection is met with in young and old subjects of either sex.

The most striking symptom is an abdominal swelling, situated above the pubes, and simulating more or less closely a distended bladder. In almost all of the cases that have been recorded retention of urine was

supposed to exist, until the use of the catheter had shown that the bladder was empty. The development of the suprapubic intumescence is attended with pain, and with more or less fever. At the same time, there is increased frequency of micturition and vesical tenesmus, due to the compression of the bladder by the phlegmonous swelling occupying the prævesical space. On careful palpation the tumor is found to be somewhat irregular and unsymmetrical in shape; its consistency differs from that of the distended bladder, being hard and firm. Fluctuation is absent until the advanced stage of the disease, in which suppuration takes place.

The symptoms generally assume a subacute character; the development and progress of the swelling are slow; after a stationary condition, lasting several weeks or months, the inflammatory process terminates in resolution, induration, or suppuration. Resolution is much the most frequent ending, occurring spontaneously, or as a result of measures of treatment (rest, counter-irritation, etc.). When the process results in induration, a hard mass is left occupying the site of the prævesical swelling, the other symptoms having disappeared. Suppuration is exceptional. The formation of pus and its progress to the surface take place very slowly. The opening may occur over the pubis, at the navel, or between these two localities. When pointing at the umbilicus, the pus apparently follows the course of the urachus. After evacuation, a fistulous orifice is left, which remains open a long time. The abscess rarely, if ever, breaks into the bladder. In one case seen by Guyon, fatal peritonitis resulted from the penetration of pus into the abdominal cavity.

The treatment recommended comprises rest in bed, counter-irritation by means of repeated vesication, ice-bags if peritonitis appears imminent, incisions as soon as fluctuation becomes manifest.

An affection closely resembling prævesical cellulitis, and slightly differing from it only by its situation, has been described by Dr. Heurtaux, of Nantes, under the name of sub-umbilical phlegmon.² He applies this designation to an inflammatory swelling situated in the anterior wall of the abdomen, just below the umbilicus. Here, in the median line, a convex, symmetrically shaped, elliptical intumescence develops itself, either as a sequel to other diseases (typhoid fever, pleurisy, confinement, measles) or without any apparent cause. The swelling, attended with little or no pain or general disturbance, follows a subacute or chronic course. Suppuration ultimately ensued in all the cases, six in number, recorded by Heurtaux. In two cases the pus escaped at the navel; in both, the opening remained fistulous for a long time. The four other cases terminated in a speedy recovery after evacuation of the pus.

Among the diseases which might be confounded with the chronic inflammatory swellings, resulting from prævesical and sub-umbilical phlegmon, may be mentioned *cysts of the urachus*, of which a curious case was recently reported by Roser.³ In this same connection an essay by Gruget⁴ on *urinary umbilical fistula following the course of the urachus* may be consulted.

Hospital Practice and Clinical Memoranda.

BOSTON CITY HOSPITAL.

CASES IN THE SERVICE OF DR. LYMAN.

PROLAPSUS OF OVARY RELIEVED BY PESSARY.

L. W., aged thirty, married; catamenia at fourteen; has always suffered from dysmenorrhœa. Has had three children, two of them delivered by instruments, the last about seven years since. Two years ago was in the hospital for menorrhagia with severe hypogastric pain. At that time there was found a deep ulceration on the left of the cervix, with a thickened condition of the cervical mucous membrane and a "dirty brownish discharge." The cervix was everted, and she was soon discharged relieved. She remained well for four months.

November 13, 1879, she was readmitted, complaining of pain and "burning" in micturition and occasional œdema of the feet. There was found slight eversion and œdema of the cervix from a very trifling laceration. Otherwise healthy, and the uterus of normal depth. Urine normal. Douglas's pouch was occupied by a prolapsed ovary, movable and tender to pressure. She suffered from pain during coition, or if constipated. The patient was kept in bed, the bowels were regulated, and the hot douche was applied night and morning.

November 28th. The ovary being much less tender, it was pushed well up, and a Smith pessary with a very thick cross-bar, to occupy the posterior cul-de-sac, was introduced.

December 1st. The pessary answers its purpose well. A still thicker one was inserted and she was discharged, to return occasionally for examination.

December 26th. Reports that she is perfectly comfortable, the pain being entirely relieved.

PELVIC PERITONITIS.

Mrs. M. S., aged twenty, entered hospital November 24th. Was married five years ago. At first coition was so excessively painful that she entered the hospital for a week for treatment, but no record is found. She miscarried three years ago. Has suffered for past four months from leucorrhœa, and she has also some symptoms of commencing phthisis. A fortnight since, at the termination of a catamenial period, her husband, while intoxicated, had a prolonged connection with her, causing great suffering. This was followed the next day by a severe chill, with heat and throbbing about the pelvis and painful micturition, which has continued ever since, the urine being frequent and very scanty. She complains chiefly of a continuous pain in the right iliac fossa. Temperature, 100.1° F. She was ordered large poultices frequently renewed, a rectal enema, and hot vaginal douches.

November 25th. Physical examination shows increased heat in the vagina, purulent leucorrhœa, the uterus movable and not in itself tender, and a large effusion into Douglas's pouch, flat, broad, hard, and excessively tender to the touch.

December 1st. The vesical irritation still continues, and is temporarily relieved by the frequent use of the catheter. Has vomited once or twice only, and there has been neither chill nor increase of temperature since her entrance. Vaginal examination shows a large in-

crease in the effusion, which now crowds the rectum into the hollow of the sacrum. There is severe pain and tenderness in both iliac fossæ and above pubes. Under the use of poultices and the douche, with opium in sufficient quantities to modify the pain, the symptoms gradually abated until December 10th, when the pain and tenderness entirely disappeared.

December 17th. There was some return of the pain and tenderness, due probably to sitting up too long yesterday. On examination, the effusion behind the uterus is found to have disappeared, some hardness remaining in front, possibly from anteversion, but it was not thought prudent to use the sound or to make prolonged digital examination.

December 20th. The patient improved very rapidly and was discharged well.

LARGE VAGINAL EPITHELIOMA IN AN UNUSUAL POSITION.

E. P., aged thirty-nine, married twelve years, entered the hospital in December. Reports that her catamenia, which began at sixteen, have been always regular and painless. Ten years ago miscarried at four and a half months, and again within the same year at six months. Has not conceived since. Two years ago first noticed that coition caused pain; catamenia have continued regular, but with more or less of metrorrhagia during intervals, which is always increased by coition; makes a clear distinction between this and the regular catamenia. Says her husband is healthy, and she gives no evidence of any specific taint. Has lost over fifty pounds the last year, but is still a strong, hearty-looking woman. Complains of more or less pain, even when at rest, in vagina, hips, and side. Two days before entrance had a severe and prostrating hæmorrhage without given cause.

On examination, the finger encounters on the posterior wall, two inches from the fourchette, a roughened, nodulated, cauliflower mass, bleeding freely and excessively painful. It occupies about half the circumference of the vagina, extending nearly to the cul-de-sac, as large as an egg divided longitudinally. Cervix uteri smooth and healthy. Examined by the rectum, which was empty; the mucous membrane was found intact and healthy, but very thin and adherent, threatening speedy rupture by the encroaching vaginal mass. As no operation was possible without the destruction of the recto-vaginal septum, the treatment was directed to the relief of pain and hæmorrhage by vaginal douches of hot water and chloral, and she was subsequently discharged at her own request.

CHRONIC RETROVERSION OF THE UTERUS, WITH ADHESIONS.

M. N., aged forty-one, single, entered hospital November 26th, with a long history of uterine troubles, for which she has been under a variety of treatment outside. She is an intelligent American woman, knows all about prolapsus and pessaries, tampons and tumors, and everything relating to ovaries, uterus, and vagina, and is ready to criticize any treatment which may be suggested. She declares that every form of pessary has been used ineffectually. She suffers from dyspepsia in an aggravated form, and from leucorrhœa.

November 28th. Examination reveals the cervix low down and pointing forwards, with the uterus completely retroverted. The uterus could be replaced, but with some difficulty and considerable pain, owing to old adhesions.

December 26th. For the last month the vagina has been freely douché twice a day, and a great variety of instruments have been tried, most of which were either ineffectual or unbearable. As the parts have become more healthy under the use of the douche, the organ is now easily retained in position, and with comfort to herself, by instruments which at first could not be borne, and she was discharged free from leucorrhœa, and with the dyspeptic symptoms very much relieved.

COMPLETE TRANSVERSE LACERATION OF CERVIX UTERI; OPERATION.

M. M., aged twenty-eight, married, entered the hospital November 14th. Catamenia at sixteen, normal; has been married eight years; two normal labors, the last nearly four years ago. She has suffered ever since last delivery from weakness, uterine tenesmus, and leucorrhœa, and with prolapsus at times to such a degree as to be recognizable by herself, rendering locomotion difficult. Had a miscarriage six months ago, which she attributes to displacement of the womb. She has of late flowed two times in every month, with offensive dark-colored leucorrhœa during the intervals. Sleeps badly, has a fair appetite, the bowels regular, and no cough or œdema. Vesical tenesmus and burning with micturition. The urine is small in quantity. Suffers from vertigo and flushings, followed by marked pallor, with headache and dyspœna on exertion. Pulse irregular and occasionally intermittent. No recognized cardiac lesion. Physical examination shows a relaxed vagina and a deep transverse laceration of the cervix uteri, extending to the vaginal angles, with the lips flattened out, everted, and denuded of epithelium. The cervical follicles being distended, these were freely incised, and the patient ordered rest in bed and a free use of hot vaginal douche.

November 26th. The parts looking more healthy, she was etherized, and the usual operation performed by freshening the edges of the cervix and bringing the lips together by three sutures on either side.

December 5th. Good union; the sutures removed.

December 13th. The uterus well in place, vagina and cervix healthy. Discharged well.

LACERATION OF CERVIX UTERI, WITH METRORRHAGIA AND SUBINVOLUTION OF THE UTERUS; OPERATION, FOLLOWED BY PERITONITIS AND CYSTITIS; RECOVERY.

M. D., aged twenty-two; entered hospital in October. Reports that she was always in good health until her second confinement, which took place a year ago. This labor was protracted, for some unknown reason, and since that time her catamenia have continued fourteen days out of the month, with profuse leucorrhœa in the intervals. Micturition normal, bowels usually constive, appetite poor.

October 30th. Examination reveals a transverse laceration of the cervix uteri and the upper part of the vagina bathed in mœco-pus; sound enters two and one half inches from the inner os, showing subinvolution of the uterus.

November 6th. Under hot-water injections the congestion and leucorrhœa have much diminished, with the everted lips of the cervix soft and movable. Several enlarged follicles were freely incised.

November 19th. Under ether the edges were freely denuded and brought into apposition by sutures in the usual way.

November 21st. The temperature has risen steadily since the operation, and is now 103.4° F. The urine has been drawn with a catheter since the operation. She complains of severe abdominal pain, and of a tumor projecting from the vulva, which proves to be a rectocele. The rectum is found to be loaded. The pain was somewhat relieved by opiate fomentations and the rectum by oil and enema.

November 24th. Menstruating. Temperature, 102° F. Complete anorexia. Pain continues.

November 25th. Has pain in right side, but otherwise feels much better. Temperature, 99.2° F.

November 26th. Sutures removed with some difficulty and pain. She is much jaundiced; expression anxious. Still has pain in right side and abdomen.

December 1st. Had an attack of bilious vomiting last evening. Catamenia ceased.

December 2d. Had a severe chill at time of visit; temperature 103.4° F.; was ordered quinine subcutaneously, followed by five grains by the mouth every four hours.

December 3d. Temperature 99° F.; pulse 80. For the next ten days she was very nervous and irritable, and suffered much from profuse sweats, but gained slowly until the 12th, when she was examined for the first time since the removal of the sutures. So far as concerned the operation the result proved exceptionally good, the cervix being of natural shape and length, and the cicatrices hardly discernible. There was no evidence of any pelvic effusion, and the condition of the vagina was normal.

December 15th. She complained of severe pain and tenesmus in the bladder and burning micturition. This increased and on the 17th the urine became very offensive and loaded with pus.

December 23d. Since last report the bladder has been washed out twice daily with carbolized water, and she has had benzoic acid internally. She is now free from pain and the urine clear.

January 5th. Had some pain yesterday, but is now up and about the ward. She remained in hospital, with occasional slight attacks of irritable bladder, for some weeks, and was discharged well January 30th.

If the operation in this case had been deferred another week or ten days, the patient would probably have escaped the threatenings of septicæmia and the peritonitis and cystitis which followed. The operation, simple as it is, should not be resorted to until, by rest in bed and careful attention to the digestive organs, the portal and pelvic circulation are quite free. The jaundice and the loaded rectum show that such was not the case in this instance.

LACERATION OF PERINEUM AND CERVIX UTERI.

E. T., aged thirty-three years, has been married two years and a half. Eighteen months ago miscarried at five months, and was delivered in March last of a child at full term. Convulsions began five hours before birth, and she was finally delivered of a very large child, with instruments, under ether. She remained unconscious for two days, but is unable to say whether the convulsions continued or not after labor. From that time has suffered from bearing down, leucorrhœa, and the usual symptoms of deranged pelvic circulation. For four weeks "the womb has been coming down," and, as she thinks, sometimes outside the vulva. She has constant desire to urinate, and is occasionally, when walking, unable to retain her water. Appetite good, sleeps well, and bowels regular.

Physical examination shows perinæum to be ruptured close down to sphincter, and involving some of its external fibres; vaginal walls relaxed and prolapsed; uterus nearly in its normal position, but subinvolved; sound entering three and one half inches; cervix uteri deeply lacerated transversely, presenting two long, thin, indurated, and inverted lips; the proper cervical mucous membrane denuded of its epithelium. She still insists that the uterus occasionally presents externally. Is directed to notify the house officer when this occurs, and the result shows the tumor of which she complains to be cystocele only, the uterus remaining *in situ* nearly. She was placed on preparatory treatment of copious hot douches, occasional scarifications of everted os, laxatives, etc., and on November 5th, the parts being in a healthy condition, she was etherized, the edges of the cervix were freshened, denuded entirely of cicatricial tissue, and drawn into apposition with eight wire sutures.

November 13th. The four posterior sutures were removed. Line of union found perfect.

November 14th. The remaining sutures were removed. Union being perfect, after a few days' rest, she was, November 18th, again etherized, the cicatricial surfaces of the torn perinæum were thoroughly removed, and the parts brought into apposition by two deep sutures passed well around the recto-vaginal septum and two others anteriorly.

November 20th. Doing well, though, as in all these cases, any movement causes excessive pain.

November 23d. Removed the two deep recto-vaginal sutures. Catamenia supervened.

December 3d. Perinæum well united with an unusually good triangular body. The anterior edge is thin, but gives ample support and complete relief to the cystocele and vesical irritation.

December 12th. Discharged, with careful directions as to bowels and the use of the douche for another month.

VESICO-VAGINAL FISTULA; VAGINAL ATRESIA FROM CICATRICES; RUPTURED PERINÆUM.

M. D., married, aged thirty-five, entered hospital September 24, 1879. Eleven weeks previously, the patient, a short but well-formed woman, was delivered of her first child, still-born, after a labor of twelve hours at full term, by a midwife. She says the child was large, and came head first, and that the after-birth did not come for eight days, and was not offensive. She first noticed incontinence of urine twenty-four hours after labor. This became more troublesome as she was able to get about, and has continued ever since. In the recumbent posture she can retain her water for half an hour. She declares that there has been no offensive discharge since the after-birth came away, but it is difficult to get any reliable history. Upon examination the whole vulvar region looked sufficiently unpromising. It was found much inflamed and bathed in offensive purulent and urinary secretions; the perinæum was torn completely to the sphincter, and upon separating the vulva the vaginal walls were found an inch and a half within, adherent and admitting only a probe. At the base of the bladder, close to the urethra, and bounded upon the farther side by the above-mentioned cicatricial adhesion, was a transverse fistula, admitting easily the exploration of the bladder by the index finger. The first thing to be done was evidently to close this fistula, to prevent the excoriations and uncleanness. To render the opera-

tion practicable, it was necessary to dilate the vagina and obliterate the adjoining cicatricial tissue. This was effected by dilating the orifice with a stiff probe until the end of the finger could be passed and tents inserted. In twenty-four hours the opening was enough dilated to admit the passage of a finger, when a second band was found completely occluding the canal high up.

October 8th. The adhesions were much softened under free use of douches and repeated stretching, assisted somewhat by the knife.

October 10th. Outer bands much dilated, and kept so by a small pessary lodged between.

October 11th. A glass plug introduced. This was kept up for a month, by which time the cicatricial tissues were absorbed sufficiently, and November 10th the patient was etherized, the edges of the fistula were pared, and four silver sutures taken. To facilitate this the little finger was passed through the urethra beyond the fistulous opening into the bladder.

October 18th. The sutures were removed, and the union was found to be perfect, except a small point on the right side, which was doubtful. It was at this point that the cicatricial band had been most unyielding and the recto-vaginal wall most thin. Further examination revealed a small capillary opening.

November 22d. The catamenia appeared for the first time since her delivery, showing that the cicatrix above had either never been entirely complete, or had yielded to pressure.

December 1st. Retains her urine in the sitting posture but loses some while walking.

December 20th. After ineffectual trials of astringents and irritants to close the minute opening by granulation, the patient was again etherized, the edges were freshened, and two wire sutures and one silk suture were introduced. This was accomplished only after several failures from the tearing out of the sutures, owing to the exceeding thinness and cicatricial character of the tissues. The attempt, however, failed, but was finally repeated successfully the 22d of January.

February 10th. The bladder was injected with milk and water, and the fistula found to be entirely closed. There is still some incontinence by the urethra, which remains widely dilated, possibly due to the introduction of the finger at the first operation. She was put upon nux vomica and belladonna. She has menstruated twice since entering hospital, and is in every respect much improved, and is no longer offensive to herself and to those about her. After recuperating for a while outside she will return for treatment of the remaining cicatricial bands in the vagina and for restoration of the perinæum.

Reports of Societies.

PROCEEDINGS OF THE BOSTON SOCIETY FOR MEDICAL OBSERVATION.

F. C. SHATTUCK, M. D., SECRETARY.

NOVEMBER 17, 1879. DR. F. H. BROWN read a paper on

IMPACTED FOREIGN BODIES IN THE EXTERNAL AUDITORY MEATS.

DR. JEFFRIES remarked that he had found in an old ophthalmic case belonging to his father a double hook, which had proved very useful in his hands in removing

foreign bodies, hardened wax, and the like from the meatus. — DR. BROWN said that such an instrument is well suited to foreign bodies which are soft, but doubted its applicability if they happen to be hard. — DR. J. O. GREEN said that a simple loop of wire proved efficient as often as any other one means, but that as no instrument or method suited all cases one's ingenuity is often taxed; great gentleness should always be used. The other important points are thorough knowledge of the anatomy of the ear and illumination of the cavity, so that the operator can see exactly what he is doing at the time.

In illustration of the injury resulting from the reckless use of instruments without thorough inspection, he narrated a case seen by him a few years before, and never reported, where an old lady broke off a piece of a glass pipette in the meatus, and the family physician, an irregular practitioner, attempted to remove it by instruments. Not succeeding, he etherized the patient, and continued his attempts for over two hours, at which time Dr. Green was summoned, and found that the whole operation had been done without illumination of the parts; as the result the whole drum membrane had been removed, so that not a vestige of it remained; the hammer and incus were wanting, and had probably been concealed after the removal. And this not satisfying the ardor of the operator, the whole mucous membrane of the inner wall of the tympanum over the promontory had been scraped away, so that the bone was perfectly bare. Two or three small bits of the glass were very firmly impacted in the irregularities of the tympanum towards the Eustachian tube, and could not be readily removed, and on account of the very weak state of the patient, she being about eighty years of age and having been under profound etherization for two and a half hours, Dr. Green advised that no further attempts should be made at that time. At the request of the family, the former practitioner resumed charge of the case, and Dr. Greene did not see her again; but some months afterwards he was informed by one of the family that the patient had had no further trouble from the ear, but was and had been for some time suffering from disease of the brain.

TORTICOLLIS SUCCESSFULLY TREATED BY DELORE'S METHOD.

DR. BRADFORD showed an arrangement which he had used with success in a case of torticollis. It consists of a simple iron frame-work, over which is adjusted a silicate bandage, and is substantially the method of treatment recommended by Delore, in the *Gazette hebdomadaire*, March, 1878, for cases in which the sterno-mastoid is not involved. The patient, a boy, was referred to him at the Children's Hospital by Dr. J. J. Putnam. Poulices, leeches, belladonna ointment, rest in bed, Little's method, were successively tried without result. As soon as the child was under ether the head could be moved in all directions. The silicate bandage was then applied over the frame-work and retained for a month, giving rise to no uneasiness. At the end of that time it was removed, and the child remains perfectly well. A frame-work is required for the reason that the silicate bandage requires several hours to set; Delore's frame-work is of pasteboard. — DR. INGALLS said that he had adopted this method in one case. It bid fair to be a success, but the frame-work had to be removed after a fortnight, because it had not been sufficiently padded. — In reply to a question

of Dr. Porter, DR. BRADFORD remarked that it is not always easy, without very careful examination, to distinguish between torticollis simplex and that from caries of the spine: this latter did not enter into any of Delore's cases. — DR. PORTER then asked how much force is required to reduce the deformity, and DR. BRADFORD answered that it varied in different cases within pretty wide limits, but was never very great.

DECEMBER 1, 1879. DR. BUCKINGHAM read a paper on

DIFFICULT DENTITION.¹

DR. PORTER alluded to the groundless fear, so widespread among the laity, that the cicatrix resulting from lancing the gums is more difficult of penetration by the tooth than the gum which has been let alone. He then spoke of the happy effect of bromide of potash in full doses in cases of irritation from teething, the drug proving often all-sufficient without resort to the lancet. — DR. T. B. CURTIS remarked that it was very difficult to form conclusions as to the benefit of gum cutting, so greatly do the authorities and the experience of individuals differ on this point. He never did it, perhaps having got a prejudice against it from the days when he was interne of Roger at the Hôpital des Enfants malades in Paris. He remembered hearing Roger express the opinion that the dangers from teething and the effect of worms were greatly overated, and never did he hear Roger even suggest performing the operation. In one case he had a chance to compare the methods. A child which had been under his care never had its gums cut, until one summer, during his absence from town, it came under the care of another practitioner, who cut the gums several times. Neither the mother nor the nurse could perceive any benefit from the procedure. Jacobi² thinks it not only useless, but even harmful to the teeth, as does also a New York dentist, J. Foster Flagg, quoted by Jacobi. — DR. C. E. STEDMAN said that the paper is an indication of how industry and research will give interest to a well-worn subject. He always carries a lancet, and feels satisfied that the operation is useful. One who has seen a child look up in his face and laugh after the operation is struck by its perforce. He has never regretted the operation save in one case, in which there was free bleeding from the gum, perhaps from clumsiness on his part. In regard to artificial food, he thought Borden's condensed milk perhaps the best single thing. At a meeting of county physicians, some fifteen years since, he was much struck by the unanimity which seemed to prevail in favor of condensed milk. — DR. BUCKINGHAM said that in his experience it is easier to get good milk in the city than in the country. The very fact that city milk is a mixture from many cows is a safeguard. — DR. ROTCH thought the paper especially valuable from a clinical point of view, and was reminded by it of the case of a child nine months of age who had had some difficulty in cutting the lower incisors at eight months. The child began to suffer from pain, was sleepless, cried persistently, and had fever. Bromide of potash and breast milk were rejected; the temperature rose to 104° F., and there was retention of urine. After twenty-four hours the gums, which were swollen and tense, were lanced. Within two minutes after this the child fell asleep for twenty minutes. Its temperature was then 102° F. After another hour the

¹ YALE JOURNAL, vol. cii. p. 3.

² Buck's Hygiene and Public Health, vol. i. p. 136.

temperature was normal; the child nursed, and had no further trouble. Dr. Rotch asked the reader whether, in his researches, he had met with physiological facts or experiments going to show that the number of teeth is any index of the capacity for digesting starchy food. — The reader replied that he had not. Certain authorities express their opinion regarding it; Monti, for instance, speaks of eight teeth as necessary, the late Dr. Buckingham of sixteen. — DR. VAUGHAN expressed his conviction that relief is afforded by gum cutting. One of his own children came to him and asked for the operation as plainly as possible. In but one case has he seen a tooth injured thereby, a lower incisor, which decayed early. — DR. J. S. GREENE spoke highly of the application of ice to the gums; it is very grateful to the children, and has often saved him from the use of the lancet, which he uses still, but not as often as formerly. — DR. PORTER recalled the case of a child which had been in apparent pain for forty-eight hours, was restless, and would not leave its mother's arms for the crib. The gums were swollen, so he lanced them in four places, and before he could wipe his lancet the child was asleep. So soundly did it sleep that the mother was alarmed, and feared that it was dead. There was no further trouble at that time. He has always lanced the gums of his own children when swollen and irritated. — DR. F. C. SHATTUCK said that he had never performed the operation, never having seen a case in private practice or in a large dispensary and Massachusetts Hospital out-patient experience in which it seemed to him indicated. — DR. DOE spoke of a child who had had convulsions with every tooth unless an incision was made. That the relief was due to the incision was shown by the fact that in his absence another physician was called in during the convulsion; bromide of potash gave no relief. Soon after Dr. Doe arrived, lanced the gums, and the convulsion ceased.

SACCULATED BLADDER.

DR. DRAPER presented the specimen, and remarked that the condition is a common incident in chronic cystitis, but very infrequent in a young and healthy man free from genito-urinary difficulty. The specimen was taken from the body of a man of twenty-three, who was accidentally drowned. On opening the abdominal cavity the distended bladder appeared as if it had a double fundus, two rounded tumors with a well-defined antero-posterior sulcus between them coming into view. The opposite surfaces of the two portions were united by tolerably firm tissue, which had to be divided by the knife, although it was evidently normal and not of inflammatory origin. The entire organ contained twenty-four ounces of clear, odorless urine. When the bladder was removed from the pelvis with the ureters and examined, it became evident that the larger sac, composed of thin membrane, was a hernia of the mucous lining through an opening in the muscular wall of the bladder at the right side, the aperture being about two inches in diameter. This sacular appendage was larger than the bladder from which it was derived.

—The fiftieth annual commencement of the College of Pharmacy of the city of New York was held at Chickering Hall on the 16th of March, and the graduating class numbered forty-four.

PROCEEDINGS OF THE BOSTON SOCIETY FOR MEDICAL IMPROVEMENT.

T. M. ROTCH, M. D., SECRETARY.

MARCH 22, 1880. DR. JAMES C. WHITE, permanent chairman, presided.

ALBUMINURIA.

DR. CALVIN ELLIS read a paper entitled *The Significance of Albuminuria as a Symptom*, of which the following is an abstract:—

The causes of albuminuria were considered under the following heads: (1.) Albuminous matters in the pelvis of the kidneys, the ureters, the bladder, or vagina. (2.) Disturbances of the circulation. (3.) Disturbances of the nervous system. (4.) Diseases of the kidneys. (5.) Changes in the blood. (6.) Indigestion.

The evidence seemed to show, —

(1.) That albuminuria frequently depends upon disturbances of the circulation of the kidneys, but, contrary to the common belief, that this disturbance is quite as likely to be owing to the diminution of pressure as to its increase or to congestion, as it is commonly called.

(2.) That the action of the nervous system depends upon its influence over the circulation.

(3.) That in disease of the kidneys themselves, the epithelium, if it have any connection with the appearance of albumen, acts mechanically rather than otherwise.

(4.) That the changes in the interstitial tissue cause disturbances of the circulation, and that serous infiltration or inflammation of this tissue may furnish albuminous products which escape with the urine.

(5.) That the blood-vessels may be so changed as to allow albumen to pass more readily.

(6.) That the blood itself may undergo certain modifications, but that a variation in the proportions of neither water nor albumen can be demonstrated.

(7.) That the products of digestion probably fail to undergo the usual changes, and consequently appear in the urine.

DR. E. S. WOOD said, in regard to the amount of albumen which occurs in certain cases where the kidney is diseased, that it was at times in small amount, and that where the morbid change was chiefly in the tubules there was apt to be much albumen. He also remarked that albumen at times appeared in the urine of women, where its source is this side of the kidney, and that it is therefore important to have the urine saved after a vaginal douche has been given. Also after the administration of certain drugs and various irritants, albumen may appear in small amount in the urine.

DR. CUTLER referred to the recent experiments of Litten on animals, in which results were obtained very similar to those of Ribbert, mentioned by Dr. Ellis. The conclusions arrived at were quite like those of Dr. Ellis in regard to the cause of albuminuria.

DR. JOHN HOMANS said that Dr. Ellis seemed to consider that albumen in the urine was a pathological and not a physiological change, and that this was interesting in reference to cases of life-insurance, where sometimes risks are accepted where albumen is present in such small amount that a specialist alone can determine the fact, and yet the person may die very soon from disease of which this albumen is a symptom;

while, on the contrary, a large amount of albumen may be present, and yet the patient appear perfectly well and often remain well.

DR. ELLIS said that the frequency with which albumen was found made him careful not to say that the kidney was affected unless casts were present and the albuminuria was continuous; and that even where a few casts were found we could not say that the kidney was affected. The diagnosis must be made by a group of symptoms, not by one.

DR. T. B. CURTIS remarked that much stress had been laid upon the frequent occurrence of albuminuria without renal disease, but that nothing had as yet been said of the existence of Bright's disease without albuminuria. He thought that there was in the profession too great a tendency to make the diagnosis of "Bright's disease" hinge upon the presence or absence of albuminuria. In the nomenclature of the Royal College of Physicians the terms *Bright's disease* and *albuminuria* are given as synonyms; and Dr. George Johnson, in his clinical lectures on Bright's disease, considers the two terms as practically synonymous. Several of the recent authorities on renal diseases, however, admit that in cases of renal cirrhosis, or granular kidney, albuminuria may at times, or even frequently, be absent. Bartels states that albuminuria is no constant symptom in this form of renal disease. He records one case in which albumen was entirely absent from the urine throughout, and in which the existence of Bright's disease was only recognized after death. Dr. Mahomed, whose recent contributions to the pathology and the clinical aspects of chronic Bright's disease are very interesting and valuable, even goes so far as to say that neither albuminuria nor dropsy is usually present in this disease, and that when present, albuminuria indicates the existence of parenchymatous nephritis occurring as a complication of the primary interstitial disease. He has, moreover, shown that out of one hundred cases observed in Guy's Hospital, in which granular kidneys were found at the autopsy to have been the cause of death, in only twenty-six cases was chronic Bright's disease correctly diagnosed during the life-time of the patient. He states, on the strength of these facts, that seventy per cent. of the patients who owe their deaths more or less directly to Bright's disease die with the chief cause of their deaths unrecognized; and he draws the conclusion that the generally accepted account of the disease and of its symptoms fails to recognize it in the great majority of cases.

DR. EDES remarked that he thought too much had been made of the exceptional cases of contracting kidney in which albumen has not been found in the urine. In most of these a more careful or continued examination would disclose it at some time or other. An examination of some of his recent cases with the sphygmograph shows the applicability of the views of Rineberg, quoted by Dr. Ellis, to cases of Bright's disease. Whereas in most of the cases of high arterial tension, as shown by the sphygmograph, some of which at least were cases of contracting kidney, as shown by large quantity and low specific gravity of the urine and the presence of casts, the amount of albumen was very small or a mere trace; in the others, that is, cases of parenchymatous nephritis, attended with a larger secretion of albumen, the tension was much less, and often much below normal. He did not see, however, how some recent writers could be so sure of a pre-

albuminuric stage of Bright's disease, as shown by the sphygmograph, since in order to prove its existence one must have an opportunity to observe for some time, perhaps for years, persons whose tracings were taken at a time when they were supposed to be healthy, or at any rate free from renal disease.

DR. J. ORNE GREEN reported the following cases:—

NECROSIS OF THE INNER TABLE OF THE MASTOID AND CARIES OF THE TYMPANUM.

CASE I. A girl aged ten years, during typhoid fever, developed purulent inflammation of the left tympanum, with perforation and ulceration of the drum membrane, followed by mastoid abscess, which ruptured spontaneously some weeks after. When I first saw her, carious bone could be felt through the fistula over the mastoid, and the meatus was obstructed by a firm fibrous polypus growing from the tympanic mucous membrane. Operation was advised, and under ether the polypus was removed by the wire-snare, and it was found that the inner wall of the tympanum was carious. At the same time the mastoid was exposed, and all of the softened, carious bone was removed by a gouge as far as possible, and a clean passage obtained for fluid from the wound through the meatus. A large surface of carious bone between the mastoid and tympanum, along the antrum mastoideum, was, however, beyond reach, and was left. The previous pain was entirely relieved by the operation, but the discharge from the wound and meatus continued, and granulations again sprang up from the carious bone in the tympanum. The treatment was thorough antiseptic syringing to insure perfect cleansing and free evacuation. During nearly a year this was continued, the general health being excellent; at the end of that time examination with a probe discovered a sequestrum within the mastoid cavity, and much carious bone was felt in the tympanum.

Under ether the mastoid was freely exposed, revealing a carious fistula through its external table; this was enlarged with a gouge till the end of the little finger could be passed in and the sequestrum could be felt moving freely; with forceps this was seized, and with a little manipulation withdrawn through the external opening. The sequestrum was 16 mm. long, 12 mm. wide, and constituted the inner table of the mastoid, including the distinctly marked sulcus of the lateral sinus. With a sharp spoon the superficial caries of the antrum mastoideum and of the tympanum was thoroughly scraped away. The mastoid and tympanum were syringed with carbolic solution, one to eighty, and wound and meatus were dressed with carbolized oil, one to ten. Not the slightest reaction followed the operation, and on the second day the child was up and about. The antiseptic syringing and dressing were continued daily. Three weeks after the cavity had diminished fully one half by the development of granulations, and no bare bone could be felt in the wound, and but a small bit in the tympanum. Five weeks after the operation, when last seen, the discharge from the wound scarcely amounted to two drops in twenty-four hours, but it was thought best still to keep the fistula open; the otorrhoea had almost ceased, the bare bone in the tympanum was nearly covered, and the tympanic mucous membrane was smooth and but slightly inflamed.

The chief point of interest in the case was the situation of the necrosis, the removal of which completely exposed the dura mater and lateral sinus over a considerable space.

NECROSIS OF THE TYMPANUM, WITH DESTRUCTION OF BOTH LABYRINTHS.

CASE II. A girl three and one half years old had purulent inflammation of both tympana during scarlet fever, and the otorrhea continued two months after, when I first saw her. Polypi filled both meatuses, and were removed under ether, when it was found that both drum-membranes had been entirely destroyed, and that there was very extensive caries in both tympana; the hearing had been entirely lost in both ears from extension of the inflammation into the labyrinths during the earlier weeks of the disease, and there was the characteristic staggering gait on walking. The treatment adopted was thorough cleansing with free evacuation of all pus, and the repression of granulations, which sprang up freely, by pressure with pledgets of cotton saturated with carbolic oil. During the next six months the hammer, anvil, and six small bits of necrosed bone were discharged naturally from the left meatus. On three of the pieces the tympanic groove is distinctly seen; the other three are portions of the cancellated structure. The discharge of the last bit of bone was followed by rapid retrogression of the granulations, and the otorrhea ceased entirely.

From the right ear there was never any discharge of necrosed bone, but the caries disappeared, probably by disintegration, the granulations shriveled up, and the otorrhea ceased in about eight months.

Any restoration of hearing was evidently hopeless from the beginning, but the child showed in an interesting way the usual gradual development of deaf-mutism. Having before the fever talked well, when I first saw her she had an indistinct enunciation and had begun to lose some words: each week it could be seen that she was losing her vocabulary, and at the end of three months but few words were used, and those could not be understood. By the end of six months all attempts to talk had been given up, and she is and must remain a case of acquired deaf-mutism, at least until old enough to be taught by artificial means. The staggering gait characteristic of labyrinthine disease disappeared very slowly, and at the end of six months was still present in a slight degree.

CARIES OF THE MASTOID.

CASE III. J. T. A., aged about forty five, was first seen in June 13, 1879. He was a school-master, in robust health except a muco-purulent nasal catarrh of long duration. Two weeks before, during an acute exacerbation of his nasal trouble, he had quite severe pain in the right ear for twenty hours, probably produced by the nasal douche, which ceased with the appearance of a thin muco-purulent discharge from the meatus, and since that time had been free from all pain in the ear, but had had some neuralgia in the facial branches of the fifth nerve. Examination showed the osseous meatus and drum membrane red and swollen, with a perforation of the drum membrane in its upper anterior quadrant; the tympanum filled with muco-purulent secretion, which could readily be blown through the perforation by Valsalva's inflation, with a distinct whistle, showing that the Eustachian tube was clear. The hearing was reduced for the watch to $\frac{1}{2}$, and there was constant hissing and throbbing in the ear. The warm douche, astringents, and antiseptics, with thorough cleansing, were used for about three weeks, somewhat reducing the redness and the amount of discharge, but not checking it entirely. About

July 12th, without any pain or fever, tenderness and very slight swelling were noticed over the mastoid, which continued for ten days, then disappeared absolutely. The tenderness was noticed only on deep pressure. The swelling was very slight, not edematous, and never red; leeches and poulticing were applied to it.

The condition of the tympanum continued the same through July, August, September, and till nearly the middle of October, in spite of all treatment. Nothing more was noticed about the mastoid till October, when tenderness and slight swelling again appeared over the mastoid, but continued for only two days, and then disappeared entirely; this occurred twice within the space of two weeks.

I then advised an examination of the bone, and on October 26th, under ether, incised the periosteum, and found a small fistula with carious walls opening into the mastoid cells about the middle of the bone. No caries within the cells could be found. The carious walls of the fistula were thoroughly scraped away, and the cells and tympanum cleansed by a weak solution of boracic acid, the liquid passing readily from the wound through the perforation of the drum membrane into the meatus. The wound and perforation were covered with carbolic cotton. The same syringing was used the next day, and again on October 29th, when it was found that all discharge had ceased from both tympanum and wound. Carbolic cotton was applied as before, and October 31st it was found that the perforation had healed. November 11th the hearing was improving, and the subjective noises were diminishing; watch $\frac{2}{3}$. December 6th he reported himself without any symptoms, "hearing as good as ever," and no subjective noises. The drum membrane was still a little swollen, the retrograde process being, as it always is, a slow one. Five months after examination showed the ear to be perfect both in appearance and in function; watch $\frac{7}{8}$.

The case was interesting from the slight external manifestations of the mastoid disease, which disappeared entirely for nearly four months, and then recurred twice in a slight degree for only two days at a time; it was also interesting from the very rapid cure following the removal of the carious bone, an otorrhea of four and half months' duration ceasing in three days, with perfect healing of the perforation in the drum membrane, and entire restoration of the functions of the ear.

POISONING BY ARSENIC.

Dr. E. S. Wood exhibited the liver and kidneys of a child supposed to have been poisoned by arsenic, which showed well-marked fatty degeneration; his remarks on the case will be printed later.—Dr. HODGES asked whether it was a fact that arsenic in these cases was the cause of preservation.—Dr. WOOD thought that it was, and in answer to a question by Dr. Ellis he also said that the arsenic especially preserves the stomach in preference to other organs.—Dr. WHITE asked if fatty degeneration had been observed in tissues after exhumation in cases where an immediate post-mortem examination had determined its ab-sence.—Dr. WOOD thought that it had.—Dr. WHITE also called attention to the development of adipocere at long periods after death, and asked if it were known that ordinary fatty degeneration went on through similar periods.

DR. DRAPER referred to a case of fatty degeneration of the solid abdominal viscera after fatal arsenical poisoning, which he had personally observed. The body from which the specimens were taken was that of an adult female. The body was exhumed eleven days after burial, and scarcely any putrefactive changes had occurred. The liver and kidneys showed well-marked fatty metamorphosis.

In answer to a question by Dr. Ellis, Dr. Draper stated that one of the earliest putrefactive phenomena was an alteration of the solid tissues simulating the fatty metamorphosis of living organs; and this result of beginning decomposition should be borne in mind in microscopic examinations in cases of mineral poisoning. The fatty changes found after arsenical poisoning are to be considered as corroborative rather than controlling signs of the mode of death. It is to be understood, of course, that the changes here alluded to have no relation to the putrefactive condition of the body called adipocere, which is not a change of the tissues into fat, but into a permanent ammoniacal soap; it is not known that the presence of arsenic in the dead body has any tendency to promote the formation of adipocere.

DR. CUTLER remarked that the appearances presented in these specimens are such as to show that they were not due to post-mortem changes, where the degeneration would be general, while here it is distinctly in the cortex of the kidney; then, too, the fat in the post-mortem change would be in drops.

DR. HODGES inquired as to how much arsenic had been recovered from the organs in these cases of poisoning. — DR. WOOD said that seven grains was the largest amount that had been found in the liver, but that of course any amount could be recovered from the stomach and intestines.

Recent Literature.

Infant Feeding and its Influence on Life. By C. H. F. ROUTH, M. D., M. R. C. P. London, etc.: Third Edition. New York: Wm. Wood & Co., 27 Great Jones St. 1879.

This work was first published in England in 1860. The second edition appeared in 1863; the third edition in 1876. It is a reprint of this latter which is now offered to the profession by the enterprising American publishers as one of the series of their Library of Standard Medical Authors. At the time this book was written, twenty years ago, Dr. Routh was one of the pioneers in enlisting English public opinion against the then existing abuses and evils to which infants were exposed; and Part I. is taken up with a very forcible presentation of their case. The statistics and facts here brought together from a large variety of sources give evidence of careful and laborious research, and must of necessity have done good at that time. It is a great relief to find, in the author's preface to the latest edition, that the government has at last interfered by several acts, which make much that was then written a matter of purely historical interest.

Part II. is devoted to the subject of lactation. There are a great many assertions in these chapters that experience cannot be said to warrant. There is too much theorizing, from which rules are laid down which, to say the least, are impracticable. We cannot

illustrate better than by referring to the directions given for the selection of a wet-nurse. A physician, as a rule, is too much restricted in the number from which he has to choose to be able to demand such high qualifications as the author insists upon. For instance, one whole chapter of twelve pages is devoted to arguments showing why the selection of a wet-nurse "from the fallen class, except in a case of extreme necessity, and where the life of the child can be saved only by employing a wet-nurse, and where none other can be found than a fallen woman, is a gross moral and social wrong." (Page 119.) We are also told "scrupulously to avoid" those belonging to the lymphatic or phlegmatic temperament, and that the nervous temperament "is to be rejected." The choice, for these reasons, should be from brunettes, and these must be of the "bilious or melancholic temperament." "Brunettes," he writes, "usually belong to the bilious or melancholic temperament. In disposition they are more gloomy and dull than blondes. The milk is richer, and a precocious child is, as it were, restrained by this milk from over-excitement in its mental manifestations. Its body has time to be formed and to develop itself before it is exhausted by undue psychological excitement, and a stronger child is the result." (Page 126.)

The responsibility in making a selection is rendered still more formidable by the importance attached by the author to the rejection of a wet-nurse where any blood relation has "labored under cancer;" "and what is true of cancer," he writes, "I would equally apply to insanity." (Page 124.)

The statement of the author, that a healthy woman, if she does not nurse, is peculiarly liable to cancer and womb diseases, is unsupported by any proof.

Enough has been quoted, we think, to show that one desirous of intelligent rules for guidance in these matters must seek them elsewhere than in this book.

Three chapters are devoted to the causes and treatment of galactorrhœa and deficient lactation. Nothing calls for particular notice in these chapters, which are rather lengthy, save the large number of drugs described, to which are attributed specific virtues in increasing the amount of milk.

The composition of milk and the various substitutes therefor (animal and vegetable) are the subjects dealt with in Part III. Two chapters are devoted to their chemico-physiological properties. There is evidence of a careful study of the older writers; but we find but little recognition of any progress made since the first edition in 1860. There are several erroneous quotations of figures, important enough to require mention. For instance: the proportion of butter in human milk is given as "1 part in 2.8," instead of 2.8 per cent. In another place we read that the "normal proportion of butter is 26.6 per cent." (Page 125.) This of course should read 26.6 parts in 1000. In like manner the proper proportion of sugar in milk is said to be "1 part in 2.3." The amount should be stated as 2.3 per cent. Casein is asserted to exist in the proportion of "20 to 40 per cent, in 1000 parts"! (Page 133.) A curious mistake is made in quoting some analyses of Dr. Hassall, ten samples of milk, which yield on an average 7.5 per cent. of cream individually, being therefore calculated to have yielded collectively 77.5 per cent. In the same way, the amount of cream for each sample of evening milk being 9.5 per cent., the ten

samples are calculated as having collectively yielded 96.5 per cent.

As to the numerous special preparations of foods described, while there is much to interest and instruct in the enunciation of principles involved in their construction, it would be unreasonable to expect to find as much help in the matter of selection for use as is to be obtained in the works of authorities nearer home and of more recent date. No one, we think, at the present day would order Liebig's food with the directions for making it as was the case when it first came into use. These are the directions, however, that we find given by Dr. Routh, without any mention of the eligible preparations now in the market and in general use, where Liebig's food is given. Many of the "foods" described by the author are unobtainable here, and likely to remain so, even if still in existence in England.

The author's conclusions are generally sound, although at times we doubt the accuracy of his reasoning. This latter seems sometimes rather fanciful, as, for instance, where he attributes, among the advantages of adding a little lime-water to the milk, a beneficial effect upon the growth of the bones and of the teeth. The substitution of sugar of milk for ordinary sugar, Dr. Routh asserts, will often check diarrhoea. The reason of this is said to be that it less readily undergoes fermentation. The sentence following this is unintelligible. It reads: "And certainly alkalinity in milk, even when rich in sugar, as that of the woman, prevents it from becoming so readily acid as cow's milk." Again, when speaking of carbonate of lime, its insolubility in distilled water, and its increased solubility in water saturated with carbonic acid, he writes, "This is a property never to be lost sight of when it is wished to strengthen a growing child." (Page 135.)

There is one exception we would make to the author's generally sound conclusions as to rules of diet, and that is his recommendation, based on its chemical and reputed physiological properties, of tea as a beverage for children.

There are two or three pages in the last chapter of this Part devoted to showing the advantages of allowing infants to suckle animals directly. It seems proper that the author should express doubt, as he does, for obvious reasons, "of the prudence of allowing a child to suck a mare." (Page 193.) And we are also instructed, where a cow is used for this purpose, that she must have a "gentle disposition." Whatever may be the theoretical advantages attainable by such a procedure, there are too many objections to make it ever practicable.

Part IV. deals with the symptomatology and treatment (principally hygienic and dietetic) of "defective assimilation" in infants. These, to most readers, will be the most interesting chapters in the book, dealing as they do with matters essentially practical, and with nursery management (and mismanagement) in all the minutia, which the physician too often neglects.

The author several times confounds thrush with aphthæ, which is of course an entirely different affection. In one place (page 10) he makes the strange mistake of employing "diphtherite" as a synonym for muquet (thrush). He speaks too of the malignant or contagious variety of thrush as "closely resembling diphtheria, and requiring an analogous treatment." (Page 235.) In two places (page 233), where the word

anorexia occurs, the author undoubtedly means pyrexia.

Typographical errors are not very numerous. We meet occasionally with sentences the meaning of which, to say the least, is obscure, if not unintelligible. Whether this is the author's fault or due to carelessness in the type-setter, we do not know. The frequent use of foreign words, such as *in lieu of*, *en passant*, *encinte*, etc., tends to mar the text.

It will generally be considered as the evidence of intrinsic merit that this book of Dr. Routh's has been selected for reproduction, so many years after it was written, by both an English and American publishing house. In addition to this compliment, Dr. Routh has the gratification to find, as he writes in the preface to the third edition, "that measures have been taken by the English government in the very direction recommended by him, and that the whole official and sanitary powers have been invoked in favor of little children."

AMERICAN MEDICAL ASSOCIATION.

THE thirty-first annual session of the American Medical Association will be held in the city of New York, on Tuesday, Wednesday, Thursday, and Friday, June 1, 2, 3, and 4, 1880, commencing on Tuesday at eleven A. M.

"The delegates shall receive their appointment from permanently organized state medical societies, and such county and district medical societies as are recognized by representation in their respective state societies, and from the medical department of the army and navy of the United States."

Secretaries of medical societies as above designated are earnestly requested to forward, at once, lists of their delegates.

The chairmen of the several sections shall prepare and read in the general sessions of the association papers on the advances and discoveries of the past year in the branches of science included in their respective sections.

It is proposed to introduce into Section II. the following laws with regard to prize essays:—

(a.) There shall be four annual prizes of two hundred and fifty dollars each, which shall be awarded at the close of the second year after announcement, as hereinafter explained, for strictly original contributions to medical and surgical progress. (b.) It shall be the duty of the chairman of each of the following four sections: (1) Practical Medicine, Materia Medica, and Physiology; (2) Obstetrics and Diseases of Women and Children; (3) Surgery and Anatomy; (4) State Medicine and Public Hygiene, to appoint annually before the adjournment of the meeting of the association three members of ability and good judgment, who shall constitute a committee of selection, and who shall, within thirty days thereafter, select and publicly announce for competitive investigation and report a subject belonging to one or other of the branches of medicine included in the title of the section. (c.) It shall also be the duty of the chairman of each of the sections mentioned to appoint annually a committee of award, consisting of three experts, who shall carefully examine the essays offered for competition, and if any one shall be found worthy of the prize as a substantial contribution to medical knowledge to recommend the same to the association. (d.) All essays placed by their authors for competition shall be in the hands of the chairman of the respective committees of award on or before the first day of January preceding the meeting of the association at which the reports of the committees are required to be made. (e.) All prize essays shall be considered as the property of the association. (f.) The names of the authors of the competing essays shall be kept secret from the committees by such means as the latter may provide. (g.) Membership in either of the two committees shall not disqualify from membership in the other; nor shall membership in the committee of selection exclude a member from the privilege of offering a competing essay.

It is also proposed that the Marine Hospital Service of the United States shall be entitled to one delegate.

—Dr. Copeman, vice-president of the British Medical Association, died in the latter days of February.

Medical and Surgical Journal.

THURSDAY, APRIL 1, 1880.

A Journal of Medicine, Surgery, and Allied Sciences, published weekly by HOUGHTON, OSGOOD AND COMPANY, Boston. Price, 15 cents a number; \$5 00 a year, including postage.

All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.

Remittances by mail should be sent by money-order, draft, or registered letter to
HOUGHTON, OSGOOD AND COMPANY, BOSTON, MASS.

THE ALCOHOL QUESTION FROM A MEDICAL POINT OF VIEW.

In an address delivered before the Rhode Island Medical Society at its last annual meeting, which has been recently printed for circulation, Dr. Caswell, the president of the society, discusses the alcohol question from a medical point of view. These remarks, in somewhat the same form, were repeated before the alumni of the Jefferson Medical College. They are so temperate and moderate in tone, and the question of the use of alcohol, whether as medicine, food, or drink, is treated with such a conscientious realization of its very vital importance to society and mankind at large, and of the serious responsibilities which the medical profession is compelled to assume in regard to it, that we take great pleasure in calling attention to the address. A temperate spirit in the discussion of subjects pertaining to intemperance is so rare, and at the same time so grateful, that of itself it goes a long way toward carrying conviction. Dr. Caswell justly observes: It must be admitted at the start that there is no subject outside of theology in which the holders of different opinions have been more violent in the defense of their own side, more virulent in denouncing their opponents. There is no subject in the discussion of which more contradictory statements have been made, all of which have been apparently supported by experiment, and there is none in which the rule for each individual is perhaps more potent. Let us endeavor to arrive at some conclusion as to the use of alcohol in health and in disease, and to canvass some of the more recent views advanced by medical men.

As an illustration, if any were needed, might have been added the well-known figures from the introduction to the volume on Population of the Census Report of 1860, in which Dr. Butler, formerly of the Hartford Retreat, shows that of 7591 cases in four leading asylums in which the causes of insanity were noted, 2253 were traced to "ill health," 812 to intemperance, and no less than 740 to religious excitement. The arguments in vogue in this State are not quite so violent as they apparently are in a certain State to the west of us, where it is reported that the inhabitants of a town objecting to the sale of liquor have lately, in carrying out their prejudice, blown up a liquor saloon with gunpowder; but the civil damage bill, which we hope the legislature will see fit to do away with, is the action under the form of law of the same blind and unreasoning energy, and a recent private social organization would have been blown to

pieces in our very midst long ago if explosive words could have done it.

Thirteen years ago this very week the late Governor Andrew made a very manly and able *exposé* of the errors of prohibition in an argument delivered before a joint special committee of the General Court of Massachusetts on the matter of license and prohibition. Its republication at the present time in pamphlet form, in a tenth edition, is at once opportune and an indication of its value and popularity. It forms an excellent companion to Dr. Caswell's address. After quoting the best modern authorities on the subject, and giving due weight to what they have advanced for or against the use of alcohol, Dr. Caswell expresses his conviction that as a medicine it can lay claim to the highest rank, and that in various diluted conditions, some of which are enumerated, its use is indicated, and in others is of very great value. In youth and health men are, as a rule, better without it; but, with Sir James Paget, he is of the opinion that "the discipline of temperance is better than the discipline of total abstinence." If one does not feel the need of such aid as the judicious use of minimum doses of alcohol affords, and a cup of cold water supplies all that the system demands, then by all means let alcohol alone; but it seems to Dr. Caswell that in our climate and with our life the majority of men who approach or have passed middle life, and certainly those who are on the downward slope, find a positive benefit in this occasional minimum use of alcohol.

In these views Dr. Caswell coincides exactly with those of the wise Dr. James Jackson, as expressed in his Letters to a Young Physician just entering upon Practice, which are quoted by Governor Andrew. Dr. Jackson says, "I would never order spirits and wines to one whom I suspected to be deficient in prudence and self-control. But, keeping these things in mind, I have often directed the use even of brandy. I do not, then, call the risk very great of such prescriptions, when made with proper caution. In regard to the benefit, in some cases of dyspepsia, and in various other cases, I have not any doubt, and, that I may tell the whole, let me say that I have repeatedly seen very great benefit from giving wine to young children. I exhort all young people in health not to adopt the practice of drinking wine. I deprecate everything which shall tend to intemperance, and I believe that many men suffer from the use of wine and spirits, even in a moderate way. But I love to tell the truth, even when it is unfashionable. I believe that very many persons are benefited by the juice of the grape, and I choose to say so. Moreover, I believe that persons disposed to intemperance are not to be restrained from indulging in their vicious propensity by the abstinence of their more prudent neighbors."

Dr. Caswell joins Dr. Bowditch in his estimate of the good influence which the more general use of light wines and beer would have upon the suppression of intemperance, and closes his remarks as follows:—

I have thus, gentlemen, canvassed the views of alcohol in its relations to health and disease, and before

close I must give expression to the hope I indulge that not one word that I have uttered should inure in any way to the injury of the cause of total abstinence. A movement which at the present day is drawing to itself such pure and noble men, such eloquent and devoted adherents, as it does, both from the clergy and from the ranks of our own profession, deserves to be regarded with the most profound respect, and to be judged most conscientiously. I accord to these gentlemen the fullest measure of esteem, and withhold from them my most earnest coöperation only on the grounds which I have presented to you. And so I leave the subject with you, as one which each individual must decide for himself but in the full light of his own conscience, and with a just and overpowering sense of all the issues that are involved.

We have drawn attention to this address as in many ways a model of what the treatment of this important subject ought to be, and the concluding passage is quoted in full as not the least praiseworthy part of it. In discussing the use of alcohol, let us by all means respect ourselves, those who may differ with us whenever they will permit it, and let us not forget the amenities of life.

MEDICAL NOTES.

—The *Medical Press and Circular* recommends the tartrate of morphia, a new preparation. Being very soluble, it passes quickly out of the system, and does not cause the frequent unpleasant after-effects of the acetate and muriate. Its great solubility makes it especially useful for subcutaneous injection. It gives rise to but little smarting or irritation, and does not clog even the finest needles.

—Thomas Smith, of St. Bartholomew's, reports another successful case of lithotripsy by Bigelow's method. The stone removed was small in size, but the operation was a good test of the comparative value of the operation, because the patient, on previous occasions, when under lithotripsy, had shown extreme sensitiveness. The recent operation caused neither discomfort nor constitutional indisposition. Concerning the patient from whom this surgeon removed four ounces of calculi in two sittings, Dr. Smith says, he has no symptom of cystitis or catarrh, and is free from pain and irritation. From a condition of urinary incontinence he has completely recovered, and his general health and strength are good. See the *Lancet* for January 10th and March 6th.

—Dr. C. A. Bryce, of the *Southern Clinic*, Richmond, Va., states that he was called to see a little boy who complained of headache in the right side of his head and through the right eye. His sight was imperfect while suffering from the pain, and there was decided periodicity about the attacks, which were much worse every other day; his nose bled very often when he was troubled with the headache. From the history of the case it was regarded as a neuralgic hemicrania, of malarial origin. Accordingly, quinine, iron, and hyoseyamus were prescribed, with no im-

provement, but an increase of the head trouble with more hemorrhage from the nose. By the use of three-grain doses of dextro-quinine three times a day, however, after the second day the hemicrania was entirely relieved and did not return; the eyesight became perfect, and the bleeding from the nose ceased.

—In the Pennsylvania Training School for feeble-minded children is a child whose memory is so retentive that after listening to a sermon or other discourse he is able to repeat it *verbatim*, even to the intonations of the speaker. This instance is cited by the *Medical Press and Circular* as a proof that memory is not necessarily a high faculty of mind.

—Dr. Lewis A. Sayre has been made an honorary member of the Dutch Society of Natural and Medical Science.

—Two more deaths from chloroform are reported in the Canadian medical journals.

—Sir Dominic J. Corrigan, the distinguished Irish physician, is dead. His earliest and most important contributions to medical literature were his essays on permanent patency of the aortic valves (1832) and on cirrhosis of the liver, which placed him "among the ablest pathologists of the day." His career as a lecturer began very early, and he held the chair of physic in the Richmond Hospital School from 1845 to 1854. The Academy of Medicine in Paris elected him corresponding member. In 1866 he was created baronet, in recognition of his high professional position and his services to Ireland.

—M. Rémy has examined microscopically the marrow of amputated bones by means of chloride of gold, and claims to have discovered nerves. Some of them contain myeline, and are of small size; others are fibres of Remak. They are very numerous, follow the course of the vessels, and are, in all probability, vasa-motor.

NEW YORK.

—The coroner's inquest in the case of Maria Otter, who was killed in the lunatic asylum on Blackwell's Island by another patient, has been concluded. In their verdict the jury find that the assistant physicians in this institution are not experienced enough for the discharge of their duties, and that their pay, as well as that of the nurses, is insufficient to secure competent persons for either of these positions. They find also that there is "a lack of proper system and a general irresponsibility by the commissioners in charge of our asylums and hospitals, who should be men qualified by education and training for the position," and they recommend that a medical superintendent be speedily appointed to take charge of the asylum on Blackwell's Island, as in their opinion one expert is insufficient to exercise a proper supervision over the two institutions on Ward's and Blackwell's islands, which double duty is now performed by Dr. MacDonald.

At the inquest Mr. Townsend Cox, president of the Board of Commissioners of Charities and Correction, testified that the assistant physicians were appointed on recommendation of an examining committee of the medical board and of the medical superintendent, and

that the chief medical assistant received \$250 a year, and others \$200 a year (including board and washing), while some were entirely without pay. The nurses received from \$180 to \$200, and were required to be able to read and write, to be of good physique, well recommended, and, apparently, of good temper. On the recommendation of Dr. MacDonald, a training-school for nurses for the insane will be organized at the institution as soon as possible.

—The Improved Dwellings Association, which was organized some months ago as a stock company, is now about to put up in the northeastern part of the city some improved tenement houses, which will in many respects be the most important buildings of this class yet erected in New York or Brooklyn. The land, which measures two hundred feet square, was purchased a short time since at a cost of more than fifty thousand dollars, and the buildings, which will occupy all the available frontage and leave a large open court in the rear, will cost about two hundred thousand dollars. The tenements will be on First Avenue, extending from Seventy-First to Seventy-Second street, a distance of two hundred feet, and for the same distance on each of the cross-streets. They will be six stories high, with a French roof, and the external design will include a combination of red brick of different shades, black brick, and a little light stone for lintels. Each set of rooms will consist of one living-room and a large and small bed-room, and each one will be provided with sink, closet, and washing-stands, while there will be lifts from the cellar for wood and coal. Of course, the greatest attention will be paid throughout to ventilation, light, drainage, and other sanitary requisites. Two hundred families in all can be accommodated, and the rents will be from seven dollars upwards per month. None of them, however, will be much above ten dollars, the price being placed at such figures as will leave the association just five per centum profit on the investment.

—The widow of the late John C. Green has built a handsome new wing to the Bloomingdale Asylum for the Insane as a memorial to her husband, at a cost of \$130,000. Her design has been to secure for female patients whose insanity is of a comparatively mild type the comforts to which they may have been previously accustomed, and to exclude from the building all the appearances of a cheerless place of restraint, which are too often conspicuous in institutions for the insane. Hence it is fitted up with all that can gratify a refined taste, and as the situation and surroundings of the Bloomingdale Asylum are of the most beautiful character, a delightful home is thus provided for these unfortunates. In connection with her gift of this memorial wing, Mrs. Green has bestowed a fund of \$200,000, the income from which is to be applied to the care of women who were formerly accustomed to the comforts of life, but who, becoming insane, have had no means to pay for their support at the asylum. It is stipulated by Mrs. Green that this fund shall be devoted to the maintenance of those who have been engaged in teaching school or music, or other similar pursuits. Heretofore all such cases have been neces-

sarily sent to the asylum on Blackwell's Island, or to some of the state institutions, where they have been thrown in contact with a more violent and frequently degraded class of patients, and deprived of all their usual comforts.

—The bill for the establishment of a state board of health has passed the New York senate by a vote of twenty-three to one.

PHILADELPHIA.

—The election for a professor of physiology and institutes of medicine by the trustees of the Jefferson Medical College has been definitely appointed to take place on the 25th of April.

—The annual meeting of the Alumni Association of the Jefferson College was held on the day preceding the commencement. Dr. R. J. Levis presented a life-size bust, in bronze, of J. Marion Sims to the association, on behalf of the surgical staff of the hospital. This bronze will be placed in a prominent position in the amphitheatre of the hospital of the college. The annual address was delivered by Dr. John B. Brinton, of the hospital staff, on March 11th, in the evening, before a large audience assembled in the lecture room of the new hospital. His subject was *The Faculty of 1841*,¹ and in his address he gave reminiscences, personal and biographical, of the members of that most distinguished faculty of the Jefferson College.

WASHINGTON.

—In the discussion before Congress on the general deficiency bill, March 16th, Mr. Singleton, of Mississippi, spoke in a manner which would show his opposition to the printing of the subject catalogue of the Library of the Surgeon-General's Office, United States Army, by characterizing the resolution which authorized the printing of the first two volumes as having been *sprung* upon the house on the last day of the previous session, and inferring that the work in the main was for the cataloguing of subject matter in *antiquated books*. He needs to be thoroughly interviewed by some of the medical profession of his State.

—On March 18th the National Medical College, as the medical department of the Columbian University, held its fifty-eighth annual commencement, with eight graduates. These graduates had all of them taken three full courses of lectures, with an intermission of seven months between each course, and, with the exception of two, also the graded course as recommended by the college association. The class, from which they graduated comprised fifty-six members, a full quota for this section. The address on the part of the faculty was given by Dr. Elliott Coues, U. S. A., lecturer on anatomy, and his theme was the Goddess Hygeia of the Greeks and her influence at the present time.

ST. LOUIS.

—At the January meeting of the St. Louis Obstetrical and Gynecological Society, Dr. S. G. Moses read a paper upon post-partum hemorrhage. After

¹ Published in full in the March number of the College and Clinical Record.

mentioning the usual modes of treatment, the reader said that if these all fail we must resort to injections of the perchloride of iron, and as this acts by forming thrombi in the uterine vessels, when we use it we must abstain from the use of frictions, ergot, or any other agent likely to produce contractions of the uterus, as these would dislodge the clots and expose the patient to a recurrence of the hemorrhage. When much blood has been lost, Dr. Moses advises bandaging the legs to prevent syncope.

—At the meeting of the St. Louis Medical Society, held March 13th, a very interesting paper, illustrated by drawings, upon the treatment of sterility dependent upon endocervicitis and endometritis was read by Dr. A. C. Bernays. The treatment which he advocated he attributed to Dr. G. Simon. The reader held that sterility, and the dysmenorrhœa depending upon it, belonged as much to the domain of surgery as stricture of the urethra or fissure of the anus; that the swollen condition of the mucous membrane of the cervix caused a stricture of the neck, and this stricture was the cause of dysmenorrhœa and sterility.

The operation by which he proposed to cure this stricture is as follows: The patient is placed in the lithotomy position; the neck is split by incisions similar to those made in Sims's bilateral incisions. Now, it has been found that this procedure temporarily cures the leucorrhœa, but that the cut surfaces reunite, and the condition of the patient becomes worse than it was before. In order to prevent this, another step is necessary, namely, a wedge-shaped piece is cut from the anterior and posterior vaginal surfaces of the neck, the cuts running at right angles to the long axis of the uterus, and the base of the wedge being external; the surfaces of these wedge-like cuts are brought together by sutures thus prying open the split cervix and exposing to view the internal os.

Dr. Bernays has performed the operation seventeen times. Up to December, 1879, he had treated fourteen cases in this way, and in regard to these was ready to give results: Five of the patients became pregnant, and three of them have been delivered. Of these five, two had been barren between six and seven years, one five years, and the other two between three and four years. The nine others, though they remain barren, have been relieved of their leucorrhœa.

MEDICO-LEGAL.

—Supreme Court of California. Where a female is solicited presently to yield her person in consideration of a promise of subsequent marriage, and does so, the contract is not one upon which she is entitled to damages upon its breach. It is not a case of seduction after mutual promises of marriage have been given between the parties. Such a contract is one for illicit cohabitation, and, being tainted with immorality, is void.

—Iowa. Injuries. Plaintiff may recover damages for medical attendance, care, and nursing made necessary by injuries received, though said services may be rendered to him gratuitously.

—United States Circuit Court, Pa. The act of Pennsylvania of March, 1850, providing for a medical examination of each vessel arriving at Philadelphia from abroad, and the collection therefrom of a fee from each person on board, is unconstitutional as to the collection of the fee. Such fee cannot be sustained as a port charge for services rendered, as the service is rendered to the city for the preservation of the public health, and not to the vessel.

—Court of Appeals of Kentucky. At common law it is not a punishable offense to produce, with the consent of the mother, an abortion prior to the time when she becomes quick with child. Case reversed and remanded. In Pennsylvania the contrary view is expressed by the supreme court, which holds that the offense, whether committed before or after the woman has become quick, is punishable at common law.

—Small v. Howard. Massachusetts. Opinion of Judge Ames. Malpractice. Village Doctor. In an action to recover damages for malpractice, brought against a physician and surgeon practicing in a small country village. *Held*: (1.) That the contract of such physician and surgeon, as implied by law, was that he possesses that reasonable degree of learning, skill, and experience ordinarily possessed, regard being had to the advanced state of the profession at the time. (2.) That he was not required to furnish, and was not responsible for, that high degree of art and skill which is possessed by eminent surgeons practicing in large cities, and making a specialty of surgery.

—Supreme Court of Pennsylvania. A dying declaration is properly admitted where the deceased makes said declaration after having been told by his physicians that he was dying, and declares to the person taking the declaration that he made the same with the belief that he was dying, although a few hours before he had said he did not believe he was in a dying condition.

—Court of Chancery, New Jersey. The return to a writ of *habeas corpus inquiring* set out that the alleged lunatic "is a lunatic and of unsound mind, and does enjoy lucid intervals, so that he is not capable of the government of himself, his lands," etc. The phrase italicized, whether read parenthetically or not, is not objectionable either in form or in fact.

Disclaim.

THE NEW CODE.

MR. EDITOR,—The draught of the new and excellent code having been distributed by the councilors to the Fellows for their careful consideration and criticism, the following changes in its phraseology are suggested, to make it still more concise and add to its definiteness and force.

Line 4, omit "for their guidance and convenience," as unnecessary.

Line 5, strike out "lend his influence to," and the expression is stronger. A physician should do more than *incline* or *tend* to encourage sound medical education. Strike out "to" in line 6 and "the" in line 7.

For the first sentence in Section II. read, "The

success of a practitioner depends upon his moral character, scientific attainments, industry, and business talent."

For the caption of Section III. read, "The Relations of Physician and Patient," because the section treats of the duties of the one and the rights of the other.

Lines 30 and 31 omit as superfluous.

Lines 35 and 36, read, "after the latter has been notified." This will relieve the physician of the very ungracious duty of giving the notice himself.

Line 44, omit "and not simply verbal," as superfluous.

Line 55, insert "artificial" or "factitious" before "mineral waters," to distinguish between those the analysis of which is published and the others, the ingredients of which are a secret.

Lines 61 to 64, read, "A consultation is called to give the patient the advantage of collective skill. Discussions should be temperate and always confidential."

Line 65, "A consulting physician should neither say nor do anything" is somewhat more direct.

Line 69, omit "punctuality is important." Truism.

From line 75 to line 80 read, "The attending physician, having stated in general terms the nature of the case, may then call in turn upon each consultant to examine the patient, the usual order being that of seniority. On retiring the attending physician may invite, in the same order, the opinion of each consultant." No well-bred man needs the two reminders as to interruptions.

In the section on fees, line 86, read, "understands and agrees to it," and strike out the whole of the next sentence.

A few other verbal alterations may be suggested:

Line 96 the words "connected," "example," and "with" may be omitted.

Line 97, for "except" read "but not for."

Line 53, omit "thus."

The changes here suggested, though not very important to the code as such, are believed to be improvements in expression.

W.

CAMBRIDGE.

THE DEGREE OF DOCTOR IN MEDICINE ABROAD.

MR. EDITOR,—The recent notices of the spurious schools of medicine in Philadelphia makes interesting the discussion during the past year in the Royal Academy of Medicine of Belgium upon the admission of foreigners to practice as physicians in Belgium without requiring of them an examination as to their abilities. M. Warlomont took a prominent part in this discussion, and his review of the laws in various countries governing the practice of medicine is useful and interesting. He made a serious mistake in referring to the United States, but that mistake was promptly and gracefully corrected when his error was pointed out to him.

In his general argument he referred to the law of Belgium, which permitted foreigners to practice as physicians without a special examination when they were provided with the diploma of M. D. granted by a university, as favoring a doctor from the University of Tinbuctoo or of Bahia, and as refusing this favor to a Fellow of the Royal College of Physicians. "In Holland, Switzerland (Allemagne), and Germany diplomas are conferred which do not carry the right to practice unless accompanied with the certificate of the

state examination (*Staats-Prüfung*). Moreover, according to the law of July 21 and the ordinance of November 11, 1879,—applicable to the Confederation de l'Allemagne du Nord,—the title of doctor is not necessary for the certificate of the state examination; thus making two distinct diplomas of medicine,—the one a doctor without the right to practice, the other giving the right to practice without the doctorate. It is not long since that, in the universities of Gießen and Jena, foreigners, *honoris causâ* and *in absentia*, could obtain [purchase] the diploma of a doctor.

"In the United States the state [general government] exercises no authority on either the teaching or practice of medicine in civil life; it is absolutely free; any one can assume the title of doctor without committing an offense, for the usurpation of the title is no offense. This depreciation of the title is completed and justified by the facility with which the universities and schools confer their degrees. The University of Philadelphia, the oldest and most celebrated of America, founded in 1762, contains the following in its regulations:—

"The candidate is required to write and defend publicly a thesis before the college, unless he be beyond the seas, or at such a distance in the interior of America as to render a voyage too difficult. In such a case he shall transmit a thesis written by himself, and of sufficient value to be approved by the faculty; the candidate will then receive the title of doctor, and his thesis will be printed and published at his expense."

"This tears aside all veils; it explains among others that fact at first declared to be calumny, but later recognized as true, that, provided with a certain sum of money, an individual who cannot read or write can be acknowledged as a doctor by sending a thesis written by a third party. In the month of December, 1871, there came to the notice of Dr. Duviol, of Paris, a letter addressed to his concierge, who at the same time was a *maître*, as follows:—

"Sir,—If you desire to obtain the degree and diploma of doctor in medicine from a celebrated university of America, let me know, and I will state my conditions. In awaiting your reply, accept, etc.,

(Signed) Médecus, 46 King Street, Jersey.

"The letter was accompanied by the following cutting from a Jersey journal:—

"Promotion aux degrés universitaires sans déplacement. Occasion unique. Les personnes désireuses d'obtenir les titres de docteur, bachelier, et maître dans les différentes facultés peuvent s'adresser à Médecus, rue du Roi 46, à Jersey, Angleterre."

"I considered this a mystification, said M. Le Fort, from whom we take these details, but nothing was more serious. Dr. Dechambre directed his servant to communicate with Médecus, and he received in reply a letter from Dr. Van Yver, calling himself a delegate of the University of Philadelphia, and offering for six hundred francs the diploma of doctor of that university. After making several objections for the purpose of obtaining positive proof of this inconceivable traffic, the sum was reduced."

This report—for it was as the representative of a committee recommending certain resolutions that M. Warlomont spoke—went much further into other details than it would be of interest to reproduce here, and was adopted June 28, 1879. Subsequently, the attention

of members of the profession in this country being called to so unfortunate a mistake, an interesting correspondence with M. Warlomont ensued, with the following result:—

“Séance of October 25, 1879. M. Warlomont obtained the floor and spoke as follows: Messieurs, in the report on the admission of foreigners to the practice of medicine in Belgium, I repeated the recital as set forth in the work of M. L. Le Fort¹ of the scandalous negotiation of diplomas made by the University of Philadelphia. The thing seemed so monstrous to the world in general that I have received from various quarters indignant protestations and demands that I prove what I have asserted. Among others was a letter from M. James Lyton [Tyson], M. Daniel, secretary of the veritable University of Philadelphia (department of medicine, University of Pennsylvania, Philadelphia, U. S. A.), who has given me some positive information upon this subject.

“It appears from this information that there is in Philadelphia a highly discreditable institution which has taken the name of the American University of Philadelphia. This institution made a traffic of diplomas, which for the most part were sold in Europe. In America the commerce no longer exists, for the fraud has been exposed, but in Europe it continues successfully.” Here follows in a review the details of the report of the action of the State of Pennsylvania on this subject, so well known to the profession, setting forth clearly and properly the irreproachable character of the Jefferson Medical College and the University of Pennsylvania.

“It appears from this long citation that, aside from the adulterated institution in question, there lives and flourishes in Philadelphia the old faculty of medicine called The Medical Department of the University of Pennsylvania, created in 1765, which has lost nothing of its ancient and legitimate reputation. This institution has recently made great efforts to perfect the system of education in the United States, and with that object has considerably lengthened its course of study.”

In conclusion, and to substantiate his corrected statements, M. Warlomont presented to the Academy certain publications of the University of Pennsylvania.

L.

DISLOCATION OF THE STERNAL END OF THE CLAVICLE IN A CHILD TEN MONTHS OLD.

BY THOMAS R. WRIGHT, M. D.,

Demonstrator of Anatomy, Medical Department University of Georgia, at Augusta.

In June of last year I was called to a neighboring drug store to see a child brought from the country, said to have something the matter with its neck. An examination showed a small hard prominence just below the top of the sternum, and by questioning the mother the following history was obtained. The baby, ten months old a week before, had fallen out of bed, striking upon its right shoulder. As the mother took it up she saw the prominence, but thinking it amounted to but little applied some kerosene, and let it alone. The child continued to fret, however, and she noticed that it carried its head peculiarly and would not use the

right hand, and upon her lifting the baby by the right arm it screamed as if in great pain. This caused the mother to look at its neck again, and finding the lump still there she brought the child to the city to see a doctor. Such a history caused me to suspect something wrong with the sternal end of the clavicle, and a closer examination confirmed my suspicion, for, passing my fingers along those bones, the course of the right one was found to be downward and below the fellow of the opposite side, and its sternal end was distinctly felt, about half an inch below the top and in front of the sternum, having been dislocated diagonally downwards upon the anterior surface of that bone. By examining the sternum the vacant articular cavity was readily felt, and by grasping the right shoulder and moving it the bone was felt to move in its new position. Being pretty well assured of the correctness of my diagnosis, I told the mother to go home, and I would call and try to replace the bone. Going out to see my little patient, shortly after, with my friend Dr. Perrin, I attempted reduction without ether; but the baby's struggles and screams were too much for us, so we gave ether to complete anesthesia, and again carefully examined the case, with the same conclusion. I then proceeded to reduce the deformity. Counter-extension being made, I grasped the right shoulder with my right hand, the thumb and fingers of the left pressing against the dislocated end of the clavicle. I then made extension, at the same time carrying the shoulder backwards and a little downwards; my left hand also gently pushing the dislocated bone towards its normal cavity. After several attempts in this manner the bone slipped into place, and could then be felt in its normal position. Remembering the formation of the articulation and the easiness with which the deformity could be reproduced, a graduated circular compress was placed over the joint, and kept there by two crossed strips of strong plaster and a figure-of-eight bandage; the arm was then bound to the side with strips of plaster, and bandaged so as to be immovable. The child was kept in this way for two weeks, when the bandage was taken off and the bone found in position. A strong strip of plaster was then placed over the joint and kept there for some time as a precautionary measure.

It may appear from the repeated examinations of this case that the writer was a little uncertain as to his diagnosis. This at first sight I admit was the case, for I had never read nor heard of a similar dislocation in one so young.² Careful examination and study of the case, however, satisfied me of my correctness, as the result seems to have proved. I have examined the child several times, before and since preparing this paper, and there is no deformity whatever.

NASAL PROBES.

MR. EDITOR.—In the criticism of my paper upon the use of large probes in the treatment of strictures of the nasal duct (which by the courtesy of the American Ophthalmological Society appears in their recently issued volume of Transactions) in your journal of February 19th, your reviewer assumes that the diameter of the bony duct is only about 4 mm., and from this stand-point finds it an easy task to make it

¹ Etude sur l'Organisation de la Médecine en France et à l'Etranger, Paris, 1874.

² Malgaigne speaks of a case in a child four years of age. Fractures et Luxations, tome ii.

appear that the employment of lachrymal probes of 4 mm. diameter, which I recommend, is irrational, and calculated rather to do harm than good.

Now it so happens that I was led to the use of these probes by a careful investigation of this very point, — the calibre of the bony canal of the nasal duct. In the Transactions of the Medical and Chirurgical Faculty of Maryland for 1877 (a copy of which was doubtless sent to your journal), page 155 *et seq.*, may be found an account of this investigation. Having supplied myself with a number of probes made of iron and copper wire, differing by about $\frac{1}{2}$ mm. in diameter, the smallest having a diameter of 3 mm. (about $\frac{1}{8}$ mm. greater than the largest probe which I had at that time used in practice), and the largest a diameter of 7 mm., and having obtained permission to make use of the collection of skulls in the Anatomical Museum of the University of Maryland, I proceeded to ascertain by trial how large a probe could be passed through the nasal ducts of each one of the thirty-nine skulls composing the collection, all of which, except two, were those of adults. No force was used, and unless the probe went entirely through the duct to the floor of the nose it was not considered to have been passed. In a number of instances the thin plates of bone which assist in forming the lower portion of the canal had, in drying, become warped and bent in such a manner as to encroach upon its calibre, and this frequently prevented the floor of the nose from being reached with as large probes as could be passed without difficulty through the more rigid upper half of the duct. Nevertheless, I found in the thirty-seven adult skulls but six ducts through which I could not pass a probe larger than 3 mm., while I discovered seventeen which permitted the passage of one of $4\frac{3}{4}$ mm., four one of $5\frac{1}{4}$ mm., one one of $5\frac{3}{4}$ mm., and one other through which my largest probe, of 7 mm. diameter, was passed with ease.

As supplementary to this, I also examined twelve ducts, with membranous lining intact, upon the cadaver, the subjects in the dissecting room of the university being placed at my disposal for this purpose. Except in one instance, in which post-mortem changes prevented the punctum from being found, the probes were introduced through the lower canaliculus, slit up in the usual manner. Through both ducts of the first subject examined a probe of $3\frac{3}{4}$ mm. (the largest which I had with me at the time) was passed with ease, and found to be so loose that it was evident a much larger one could have been introduced. In one of the remaining ten (in which pathological contraction was suspected) a probe of only 3 mm. could be passed, and the fellow to this admitted one of but $2\frac{3}{4}$ mm. In all of the others, however, probes varying in size from $4\frac{1}{4}$ to $5\frac{1}{4}$ mm. (the latter in three instances) were passed to the floor of the nose without difficulty.

From these measurements it will be seen that in recommending a probe of 4 mm. diameter for the dilatation of nasal-duct strictures I have at least kept well within what may be termed anatomical bounds, and especially when it is remembered that I have not advised that this, the largest of the series of probes which I have proposed, should be used in every case, but have gone so far only as to express my conviction that the instances in which it might not be used with advantage were exceptional.¹ Indeed, so great

is the contrast between the size of this probe and the size of the largest which I passed upon the cadaver that I have felt myself open to the charge of inconsistency in not using in exceptional cases one still larger, since I have laid especial stress upon the importance of restoring the strictured canal to its normal calibre; and, unquestionably, even a probe of 4 mm. will not accomplish this in every instance.

One other point you will permit me to refer to: the statement of your reviewer that my paper "contains an account of the cure of five cases" of stricture "out of a total of twelve" can convey, as it seems to me, but one impression, — that in the seven cases not described as cured the treatment had failed. What I did say was that I had used a probe of 4 mm. diameter in twelve cases; that in one of these the treatment had been interrupted by the patient leaving the city, and the stricture had subsequently returned; that in three — two of these, however, being in the same subject, an old woman, sixty-six years of age, with ozena of long standing — the treatment, though fairly tried, had been productive of but temporary benefit; that in five a complete cure had been obtained; and that the remaining three cases were still under treatment, with a good prospect in each of a favorable result. In two of these the result which I anticipated has since been attained. In one the probe has not been passed since August last, and in the other since September, yet up to the present time the canal in each remains freely pervious, as is shown by the ease with which air can be blown through it. In the third case the probe is still being used, the treatment having been interrupted for several months by the patient being away from the city.

By a singular coincidence, while on my way, a few days since, to inquire after one of the patients I have just referred to, I encountered on the street one of the cases in which I had reported but temporary benefit from the large-probe treatment (Case VII. in my paper). To my surprise, I found upon inspection (though the day was windy) no stillicidium whatever, and the sac containing neither mucus nor tears. The duct was not pervious to air, but as she said the tears troubled her only occasionally, when exposed to the cold, it seems likely that it is not completely occluded, and that the benefit which she derived from the treatment was more permanent than I had supposed.

SAMUEL THEOBALD.

BALTIMORE, March 6, 1880.

DEATH FROM NARCOTISM.

MR. EDITOR, — I report the following case as having some points of interest: —

W. D. D., aged fifty-one, carpenter, had been insane for a year and a half, the form of insanity being melancholia. For a year or more he had been in the habit of taking, when necessary to produce sleep, one or two teaspoonfuls of the following mixture: —

R Chloral hydrat.	℥iii.
Potass. bromidi	℥iv.
Morphine sulphat.	gr. vi.
Belladon. ext.	gr. iii.
Aque	℥iv. M.

This made a mixture of about eight ounces.

On February 22d, at six p. m., he took four ounces

¹ Archives of Ophthalmology and Otology, vol. vi. p. 479.

of this compound at one draught. He began to show the effects of the dose in five minutes by a staggering gait, and in about fifteen minutes he was insensible. The whites of two eggs and a quantity of mustard and water were given to him in five minutes after the ingestion of the dose, and in the course of twenty minutes he vomited thoroughly, as reported by attendants. I saw him in an hour and a half after the draught was taken.

He was completely narcotized. His pulse was intermittent, fluttering, and sometimes could not be felt. The heart sounds could not be heard. Respiration 24 to the minute, skin cool, and pupils contracted.

Mustard and heat were applied to the extremities, and a hypodermic injection of one fortieth of a grain of atropia sulphate was given. Whisky and brandy were administered in same way every few minutes. In half an hour the atropia was repeated, and in a few minutes an improvement in the heart's action was perceptible.

At ten P. M. his pulse was 93, full and regular, the heart's sounds distinct; respirations 24, deep and regu-

lar; countenance more natural; skin warm; and thus he continued, with some variations in frequency of pulse, till a little before one A. M., when there was a slight loss of force in the heart's action. The atropia was again administered, as well as the brandy and whisky, but the heart continued to beat more and more feebly, its sounds being inaudible for half an hour previous to his death, which occurred at 2.15 A. M. Pupils remained contracted throughout. Respiration never very slow or irregular till ten minutes before death.

Yours respectfully, T. W. PARSONS, M. D.
PORTSMOUTH, N. H.

THE PROPOSED MEDICAL LAW.

MR. EDITOR,—Having been told that my name had appeared in a petition against the proposed law for regulating the practice of medicine, I would say that I am *in favor* of the law, and have signed no petition of any kind against it.

WALTER CHANNING.

Two thousand two hundred and fifty deaths were reported; 767 under five years of age; principal "zymotic" diseases (small-pox, measles, diphtheria and croup, diarrheal diseases, whooping-cough, erysipelas, and fevers) 370, consumption 389, lung diseases 335, diphtheria and croup 141, scarlet fever 58, measles 37, whooping-cough 36, diarrheal diseases 28, typhoid

fever 27, malarial fevers 14, erysipelas 12, cerebro-spinal meningitis 10, small-pox five, typhus fever one. From measles, New York 11, Philadelphia eight, Brooklyn six, Pittsburgh three, St. Louis and New Orleans two, Baltimore, Boston, New Haven, Lawrence, and Salem one. From whooping-cough, Boston five, New York, Philadelphia, Brooklyn, and New Haven four, Pitts-

burgh three, Baltimore, Cincinnati, and Cleveland two, St. Louis, New Orleans, District of Columbia, Charleston, Lawrence, and Salem one. From *malarial fevers*, New York and Brooklyn three, St. Louis and New Haven two, Baltimore, Boston, District of Columbia, and Cleveland one. From *erysipelas*, New York three, St. Louis two, Brooklyn, Cincinnati, District of Columbia, Milwaukee, Fall River, Chelsea, and Milford one. From *cerebro-spinal meningitis*, New York five, Fall River two, Philadelphia, Pittsburgh, Nashville, and Worcester one. From *small-pox*, Philadelphia four, District of Columbia one. From *typhus fever*, Philadelphia one. One hundred and sixty-two cases of measles, 34 of scarlet fever, 32 of diphtheria and croup, four of whooping-cough, and one of typhoid fever were reported in Brooklyn; diphtheria 21, scarlet fever nine, in Boston; diphtheria 19, scarlet fever five, in Milwaukee; scarlet fever 18, diphtheria eight, erysipelas two, croup one, typhoid fever one, in Providence; scarlet fever two, diphtheria two, in Cambridge; scarlet fever 11, in New Bedford. Diphtheria is quite prevalent in different parts of Marblehead. The death-rate of whites in District of Columbia was 15.05, of colored 51.07.

The total number of deaths, and of deaths under five, reported was considerably more than for the previous week. Lung diseases, scarlet fever, and small-pox were more fatal; typhoid fever, erysipelas, and measles caused fewer deaths than in the previous week. In 32 cities and towns of Massachusetts, with an estimated population of 954,260 (population of the State about 1,690,000), the total death-rate was 21.47 against 19.49 and 22.47 of the previous two weeks, lung diseases having been more fatal, typhoid fever and scarlet fever less so than in the previous week.

For the week ending February 28th, in 145 German cities,

with an estimated population of 7,680,836, the death-rate was 27.1 against 27.4 and 27.5 of the previous two weeks. Three thousand nine hundred and ninety-eight deaths were reported: 1843 under five: pulmonary consumption 607, acute diseases of the respiratory organs 573, diphtheria and croup 159, typhoid fever 81, whooping-cough 69, scarlet fever 57, measles and *rüheln* 31, puerperal fever 28, typhus fever two, small-pox (Kö-nigshütte) one. The death-rates ranged from 11.4 in Carlsruhe to 38.7 in Strassburg; Königsberg 35.5; Dantzic 30.4; Breslau 30.5; Munich 32.9; Dresden 21.2; Cassel 24.0; Berlin 26.2; Leipzig 23.1; Hamburg 30.2; Hanover 24.7; Cologne 26.4; Frankfurt 26.0. For the same week, Vienna 28.8; Paris 31.0, — small-pox, diphtheria, and typhoid fever continuing very prevalent.

For the week ending March 6th, in the 20 English cities, with an estimated population of 7,499,468, the death-rate was 22.1 against 23.1 and 25.0 of the previous two weeks. Three thousand one hundred and eighty-one deaths were reported: diseases of the respiratory organs, 390, whooping-cough 209, scarlet fever 99, measles 74, diarrhoea 19, diphtheria 13, small-pox (London eight, Bristol one) nine. The death-rates ranged from 17.5 in Bradford to 28.5 in Plymouth; London 22.9; Birmingham 19.0; Liverpool 24.6; Manchester 22.6; Leeds 20.6. In Edinburgh 23, Glasgow 23, Dublin 36 (small-pox four deaths). In the 20 chief Swiss towns, diphtheria and lung diseases were widely prevalent and fatal; scarlet fever and typhoid fever were prevalent; small-pox had declined, there being only one death reported (in Geneva).

The meteorological record for the week in Boston was as follows:—

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U. S. ARMY, FROM MARCH 20, 1880, TO MARCH 26, 1880.

PERIN, G., lieutenant-colonel and surgeon. Upon being relieved by Surgeon Magruder, to report in person to commanding general, Department of Dakota, for duty as medical director of that department. S. O. 63, A. G. O., March 22, 1880.

MAGRUDER, D. L., major and surgeon. Relieved from duty in St. Louis, Mo., and to report in person to commanding general, Department of the Missouri, for duty as medical director of that department, relieving Surgeon Glover Perin. S. O. 63, C. S., A. G. O.

BYRNE, C. C., major and surgeon. In addition to his duties as post surgeon, Fort Snelling, Minn., to take charge, temporarily, of the medical director's office at these headquarters. S. O. 30, Department of Dakota, March 20, 1880.

GIRARD, J. B., captain and assistant surgeon, Fort Davis, Texas. Granted leave of absence for twenty-five days, with permission to leave the department. S. O. 55, Department of Texas, March 16, 1880.

MCCREERY, GEORGE, first lieutenant and assistant surgeon (recently appointed), now at Fort Columbus, New York harbor. To report in person to commanding officer, Department of Arizona, for assignment to duty. S. O. 63, C. S., A. G. O.

SCHUE, E. D., first lieutenant and assistant surgeon (recently appointed), now at David's Island, New York harbor. To re-

port in person to commanding officer, Department of Arizona, for assignment to duty. S. O. 63, C. S., A. G. O.

NEWTON, R. C., first lieutenant and assistant surgeon (recently appointed), now at Fort Stanton, New Mexico. To report by letter to commanding general, Department of the Missouri, for assignment to duty. S. O. 63, C. S., A. G. O.

COCHRAN, J. J., first lieutenant and assistant surgeon (recently appointed), now at Fort Wingate, New Mexico. To report by letter to commanding general, Department of the Missouri, for assignment to duty. S. O. 63, C. S., A. G. O.

BOSTON SOCIETY FOR MEDICAL OBSERVATION.—The annual meeting will be held on Monday evening April 5th, at eight o'clock, at the hall of the Medical Library Association. Reader, Dr. F. H. Davenport. Subject, Relaxation of the Pelvic Ligaments. Annual Election of Officers.

FREDERICK C. SHATTUCK, M. D., Secretary.

CLINICAL LECTURE.¹

BY J. M. DA COSTA, M. D.,

Professor of the Principles and Practice of Medicine in the Jefferson Medical College, Philadelphia.

A CASE OF GRAVES'S DISEASE (EXOPHTHALMIC GOITRE), WITH REMARKS UPON ITS PATHOLOGY, ETIOLOGY, AND TREATMENT.

GENTLEMEN,—You will remember that at the conclusion of our last clinic we had this patient before us, suffering with what I pronounced to be exophthalmic goitre. He gave us the following history of his illness: His name is E. H. McC., twenty-six years of age, single, a native of Pennsylvania; of late years he has been engaged as a porter. He is ignorant of any inherited tendency to gout or rheumatism, and positively denies syphilis. He served in the late war as a drummer boy, and he tells us that during the battle of the Wilderness he was subjected to strong excitement, which brought on violent palpitation of the heart. After the war while engaged as a porter in a store, he was obliged to do heavy work. About Christmas, 1877, he strained himself in lifting a heavy box from a shelf, the strain falling upon his arms and chest. Shortly after this occurred, he noticed that palpitation of the heart was likely to follow any unusual exertion. During the next few months the palpitation became a prominent symptom, and the front of the neck perceptibly swelled; this was noticed by his friends, who afterwards called his attention to a prominence of the eye-balls. In April, 1878, these symptoms had become marked, the thyroid gland was decidedly enlarged, principally on the right side; and he suffered from dyspnoea.

In July, 1878, his boat was upset while out sailing, and he had to swim a long distance. When finally picked up, he was completely exhausted. The disease was evidently aggravated by this prolonged exertion, as he has not been nearly as well since, and the following October he had to give up his occupation on this account; he now was quite short of breath, his voice was altered, and his goitre was so large that he was forced to give up the use of a collar. His general nutrition, however, was good, and he had no pain in the enlarged gland.

He denies that he has been intemperate, but drinks occasionally; tobacco he has not used to excess, but tea and coffee he is very fond of, and has always been accustomed to their use several times a day.

Since stopping his work the heart does not palpitate so violently; the tumor is not so large, but the eyes are still prominent and staring.

He is naturally rather quick and irritable, but his movements are disturbed, he is easily agitated, and the limbs tremble after active exertion. When admitted, it was noted that the right lobe of the thyroid was quite large, the left being swollen to a less degree; the enlarged right lobe imparting a distinct sensation of thrill when pressed firmly between the forefinger and thumb. The circumference of the neck around the gland was fifteen and three fourths inches. You readily recall his condition when he was before you a week ago. His eyesight was good, notwithstanding

the marked prominence of the globes. The man was perfectly well nourished, certainly not anæmic looking; he had a good color of his lips, of his gums, and of his ears. His respirations we found to be 40 in the minute, but this we thought was partly because he was hurried when in your presence, for in the wards the rate was generally about 30; we may say, therefore, that the respirations were still above the normal. The precordial region was lifted with the forcible contractions of the heart; the apex beat was thumping; the pulse was then 120, although but 106 in the ward. Examining the cardiac region a little more closely, we found this state of things: the forcible impulse could be seen in two intercostal spaces. The apex was beating two inches outside of the left nipple in the sixth intercostal space. The area of impulse was therefore visibly displaced as well as extended. The percussion dullness began at the third rib, and extended beyond the right border of the sternum and downwards to the liver; dullness also existed beyond the left nipple, the apex being located as above stated. Having marked out this area with ink, you all recognized the increase in the size of the heart. The transverse diameter was six inches, perpendicular diameter six and one fourth inches, longest diameter (oblique) eight and one half inches. The characteristic appearance of the enlargement showed that the hypertrophy chiefly involved the left ventricle. Auscultation of the heart revealed the facts that the first sound at and towards the apex, where it was dull and heavy, was partially, not entirely, replaced by a systolic murmur, short and not very harsh. That murmur was also traced upwards, but towards the left base it nearly disappeared. At the right base, at the aortic cartilage, the second sound of the heart was comparatively distinct and valvular. Listening to the arteries of the neck, we found a systolic murmur, which was harsher and louder than that heard over the heart. It was most marked in the left carotid. The murmur was also feebly perceptible, in the bend of the arm, more particularly higher up in the brachial artery; it was also faintly heard in the radial artery. I may say that we had in this case a generally transmitted arterial murmur, since it was also heard in the femorals just below Poupart's ligament. To this I add, to complete the examination, that there was no disease of the lungs and no enlargement of the spleen. This last note I made because he had at one time suffered from intermittent fever. The liver was about the normal size; it was certainly not enlarged; and the urine was normal.

After this examination, made a week ago, I told you my diagnosis, and while we examined the case and prescribed for it, and discussed to some extent the clinical record, there were still several points remaining for consideration, which want of time prevented me from taking up, and I promised you that we would study more fully the pathology and aetiology of the case, this morning. The man presents as marked an illustration of the affection known as exophthalmic goitre, or Graves's disease, as it is possible to have. This malady, as the case before you shows, is one easily recognized by the prominent eyes, enlarged thyroid gland, and disturbed action of the heart. In addition to these salient symptoms there is often present a symptom which I do not know that I can claim as existing here, that is, considerable nervous disturbance; although, as you have heard, he is rather irritable in his disposition, and is sometimes agitated, he is

¹ Reported for the JOURNAL. Delivered January 17, 1880.

not decidedly emotional. I do not know, I say, that this exists here to any marked degree; but I am told that the patient is what people would generally call rather a nervous man, and, indeed, has given considerable trouble since admission by his quarrelsome disposition. These clearly recognizable symptoms, to which I have just alluded as characteristic of exophthalmic goitre, are most likely to occur in persons of a highly nervous organization, and, therefore, preëminently in the female sex. The vast majority of the cases that you will be called upon to treat will be women. I have met with practitioners who say that they have never seen an instance of Graves's disease in a man. My experience will not allow me to assert this, for scarcely a year passes in which I do not see such a case in the male; but the great number of cases will be women. Certain it is that the emotional nature which is a prominent feature in the disorder has some thing to do with its appearance in the female sex. And, gentlemen, in following out this train of thought, we must admit that, while the emotional nature of woman seems to render her more liable to the disease, and those men who are of a nervous type are also more apt to be affected by it, there must be some connection or dependence between the disorder and the temperament, or, in other words, that a form of local irritation has something to do with the emotional disturbance. Let me also add, as bearing upon this portion of the discussion regarding the connection of the now familiar signs with the emotional type, — let me add, that a fair proportion of cases have been reported where the disease seems to have been directly due to nervous disturbance and shock. If I am not mistaken, Fothergill gives the history of a lady in whom the disease was ascribed to the shock produced by the sudden announcement of the death of one of her relatives.

The reason that I am developing for you this portion of the subject, suggesting some clinical connection between the temperament of the individual and his nervous condition and the disorder, is because I wish now to make some remarks upon the pathology of the affection, and more particularly its aetiology. The symptoms are well known, but can we say why this heart is irritable, why the thyroid is enlarged, why the eyes are so prominent? The proximate cause and relation of these symptoms we understand, but the remote or original cause is unknown. It is supposed by some, on account of this clearly recognized connection with nervous disturbance, that the disease originally resides in the sympathetic nervous system, more especially in the sympathetic ganglia in the neck; the irritation of which disorders the innervation of the heart through the cardiac plexus and intra-cardiac ganglia, leading to disorderly action and palpitation, and finally hypertrophy; the enlargement of the thyroid and the projection of the eyes being produced by the constant fullness of the blood-vessels. This view has received a certain amount of support from the fact that in several post-mortem examinations of cases which have been afflicted by this disease the ganglia of the neck have been found to have undergone partly a fatty and partly a fibroid change. But this does not occur in all cases of exophthalmic goitre, and we therefore cannot look upon this affection of the ganglia as the sole cause of the disease. Another view is this: while adhering to the nervous irritation, others claim that the entire disturbance can be explained by alter-

ation in vaso-motor activity, so that the blood supply of the heart itself is affected and its nutrition impaired. Disturb this system and you will have disordered action of the heart, palpitation, and the other symptoms naturally follow. I may say of this, however, as I did of the preceding, that it is as yet a theoretical view, merely a hypothesis. Notwithstanding these plausible explanations of the presumed causation of exophthalmic goitre, that I have been trying to make clear to you, we must acknowledge that while the disease is seated primarily in the nervous system its exact site is unknown. As bearing upon this question of the involvement of the nervous system, and particularly of the sympathetic system, Trousseau called attention to a sign which is here present, and on which he laid particular stress. As I draw my thumb-nail on its flat surface across this man's forehead, pressing rather firmly, you notice the prominent red mark, the *tâche cérébrale*, following it. This red line is also seen in other diseases of the brain or its membranes accompanied by disordered blood supply, where the capillary circulation of the brain is permanently affected. But Trousseau laid this down also as one of the points confirming the view that the disease is due to vaso-motor disturbance. The facts in the case I do not deny, but the explanation I cannot wholly accept.

Having discussed the pathology of this interesting affection as far as it is known, let us return briefly to the consideration of the clinical phenomena; taking this case as the text for a more complete discussion of the course of the disease and its customary appearances.

In the first place, you ask, Will we usually find this condition of the heart in exophthalmic goitre? This heart is enlarged, very much enlarged, and in a state of greatly dilated hypertrophy, with obvious valvular disease. Will this happen as the rule? No, gentlemen. More generally you will have, at least at first, simple functional disturbance; then as the disease progresses, the palpitation becomes a prominent symptom; there is very constant cardiac over-action, with which you will have a moderate degree of hypertrophy. That is the connection. Such a marked degree of hypertrophy, with greatly increased impulse and extended area of percussion dullness, — which I marked out for you in this case at the last clinic, — is unusual, and indicates a great preponderance of cardiac disorder in this particular patient. I must impress upon you that, however remote the cause of the symptoms may be in the nervous system, the enlargement is the direct result of the over-action of the heart. The prolonged excitement of the organ finally ends in hypertrophy. Now in connection with this subject of heart difficulty in a case of this kind, let us inquire, What is the meaning of the marked murmurs that we have in the heart and that are usually not constant? These murmurs, as a rule, are due to hypertrophy and over-action; they do not necessarily represent valvular disease, at least valvular insufficiency of persistent form. It is true that in a certain proportion you will have an associated organic valvular disorder, though without any direct connection with the symptoms of exophthalmic goitre; but in the vast majority of cases you do not have such a complication; the murmurs are produced by excitement. Indeed, where such persistent murmurs occur I am inclined to believe that valvular imperfection has followed the dilated hypertrophy; the cavities of the heart are stretched and over-distended, so that the valve becomes incompetent.

These are some observations upon the state of the heart in this rare disease; let us now study the thyroid gland. This man has a very typical illustration of the exophthalmic goitre. Look at it. It is not symmetrically enlarged, the two sides are unequal; and this agrees with my former experience that one side is usually developed more than the other. Moreover, the gland varies in size at different times. When he is under strong excitement, and the heart acting with unwonted force, the gland will swell up even more. The facts that the gland is variable in size, and that one side is larger than the other, are of general occurrence in this disease. Let me add, I have never seen a very large goitre in this affliction. I have yet to meet a case where the thyroid gland is as much enlarged as it often becomes in ordinary goitre; the exophthalmic goitre never reaches such extreme proportions.

Now let us discuss the eye symptoms. What is the reason of the swollen, prominent, and staring eyes? The reason generally given is that the capillary vessels of the fatty tissue upon which the eyes rest are congested and full of blood, and push the globes forward. Further observation has shown that the cushions upon which the eyes are placed are also actually hypertrophied by increased deposit of fatty matter and areolar tissue. Therefore the projection is principally mechanical from congestion and deposit in the orbit. This protuberance of the eyes sometimes reaches the point that the patient is unable to close the eyes completely; the eyelids remain partly open even during sleep. In this case we have noticed the condition to a certain extent. Since the lids do not entirely close, part of the conjunctiva and cornea is continually exposed, and, as Von Graefe has pointed out, you will have as a result conjunctival inflammation, keratitis, or ulcers of the cornea in marked cases of Graves's disease. Does internal examination with the ophthalmoscope reveal any intraocular changes? Usually a little fullness of the vessels; nothing more. We are now making some observations upon this point, and will report the results on a future occasion.

I have already said something in regard to the mutual connection between the aetiology and the clinical symptoms. I repeat that they all come directly from the heart, the increased force and over-action of which produce the swelling of the thyroid, and cause the prominence of the eyes; but is this all? No; there must be something behind the heart which causes this train of symptoms, or else we would have the exophthalmos and enlarged thyroid in every case of cardiac hypertrophy, which we do not have. There is a "something beyond," which is the unknown quantity in Graves's disease.

What is the prognosis? I think that a very large proportion of these cases get well. I have seen patients with thyroid enlargement and prominent eye, entirely recover. I could tell you, if time would permit, of cases from my private practice, where the patient has been under observation for years, in which, in the course of time, the eyes receded into their sockets, the goitre disappeared, and the heart became normal in its action except under periods of unusual excitement. Undoubtedly these cases may recover almost entirely. Therefore, when you see a case early, you may generally give a favorable prognosis. But when you have marked cardiac enlargement, as in the present case, the prognosis is less promising. You may succeed in

making the eyes retreat and in reducing the thyroid, and even may partially control the heart, but you will never entirely relieve the case as long as the hypertrophy exists. So much for the prognosis: good if taken early, but impaired later by the varying amount of cardiac enlargement which has followed the disease.

In regard to the regimen, it must be modified according to the case. No one treatment is the right treatment for exophthalmic goitre. In the case of a woman with marked anæmic appearance, I give iron in connection with any form of tonic or other remedy that I think will be of service. But I am forced to say that I think that iron has been abused in the treatment of exophthalmic goitre. What would be the use, I may ask, of giving iron to this patient? Look at his florid face, red lips and ears. It would only act as an irritant, and hence injurious. Iron should be restricted to those cases where anæmia is underlying the malady, or at least is a marked feature of it. In nearly all cases digitalis and belladonna are useful, and I almost always keep my patients under their influence. Generally there is not marked cardiac enlargement. Some of you may ask, Why have you not used digitalis here? Why have you trusted to veratrum viride in preference to belladonna? On account of the cardiac hypertrophy. The heart needs control, and I concluded that aconite or veratrum viride would give better results, especially the latter. Therefore, although digitalis would be otherwise indicated to regulate the circulation by its action upon the nervous system, the hypertrophy of the heart forbids its use. This man has taken the following prescription:—

R Ext. veratri viride flid. gr. i.
Syr. zingiberis,
Aque aa m. xxx. M.

three times a day for the last week. During this time his heart has decreased in frequency and force, and the pulse is less bounding. Let me tell you, in addition to the above remedy, that absolute rest in bed has been insisted upon as part of his treatment, thus taking the strain off from the circulation; treating it, as you observe, almost like a case of aneurism. Remember that rest in bed of itself will reduce the frequency of the heart, and relieve it of the strain caused by general muscular action.

What shall be done for the enlargement in the neck? We prescribed the frequent application of ice in a bag, in order to act upon the capillaries there and diminish cell action. You will be interested to learn that the immediate effect was to diminish the gland one fourth of an inch in the first forty-eight hours. We therefore have continued it. This treatment, indicated with a light diet, consisting chiefly of milk, eggs, and a few oysters occasionally, and enforced recumbent position shall be the regimen we shall adhere to in this most striking illustration of exophthalmic goitre.

[During the progress of the treatment a very interesting fact was noticed, which has some bearing upon the opinion above expressed, concerning the nervous origin of the affection. After the ice treatment had been employed for a week, and the swelling had declined about an inch in circumference, he was found one morning in a state of great excitement, a death having occurred in the ward during the night. It was found that the goitre had suddenly again increased in size, in sympathy with the nervous agitation, and was now nearly as large as upon admission. The ice application was continued and rest in bed strictly enjoined,

with a restricted diet. After progressing to a certain stage the ice treatment lost its effect; the patient became impatient, and left the hospital satisfied with what he had gained, the annoying symptoms having largely if not entirely passed away. — *REF.*]

PAROTID SWELLING AFTER TYPHOID FEVER; TREATMENT BY ICE; A RARE COMPLICATION.

I will now show you a rare case of entirely different character. The man (a sailor, eighteen years of age,) about to be presented before you has had typhoid fever. I do not know that his case was marked by anything peculiar during the fever. It was, perhaps, a more severe case than usual. At times the temperature reached 105° F., and he had a great deal of muttering delirium. There was also running through the course of the disease a little more diarrhoea than is customarily met with. But, finally, the man began to convalesce, so that upon the 28th of December his temperature was down to 99° F.; it then still further decreased, so that on the first of this month it had reached 97.5° F. All fever disappeared, and we were commencing to give him a less strict diet. Constipation now began to be the rule instead of the diarrhoea, and we were obliged to interfere to produce an action of the bowels.

I state this in order to show you how completely this man had convalesced, when, on the 12th of this month, there was a slight increase of temperature, and he complained of stiffness in the neighborhood of the angle of the jaw near the right parotid gland; there was also decided swelling in this location. When we examined the face we found that this part was tense, swollen, slightly red, and painful to the touch. The pain, stiffness, and swelling went on for a day or two, notwithstanding the application of iodine by the resident physician; they were associated with increasing fever, though it did not again reach the decided elevation of typhoid fever. After the third day the temperature fell, until this morning it is not higher than it was during convalescence; being now 98° F. Ever since the 12th, this hard swelling which you see here has continued. For a few days it decidedly decreased, but during the last two days it has again enlarged.

This morning the hardness and tension of the parotid gland are very evident. The tension is so marked that the patient cannot open his mouth, and has great difficulty in eating. There is but little redness now, but considerable pain exists in this hard tumefaction. The glands of the neck lower down are not implicated; the submaxillary glands also are not swollen. The disease involved primarily the parotid gland, but the tissues around participate in the tumefaction.

What is the meaning of this gland involvement after typhoid fever, and what are the clinical features which claim our attention?

I have said that this complication is rare after typhoid: it is so rare that Trou-seau and Chomel each only saw one case; Murchison, in his enormous experience, only reports six. I have met with only two or three such cases prior to this, which I exhibit to you here as one of parotid swelling, a sequel of typhoid fever.

You will now ask how it comes on; what is its meaning; does it modify the prognosis; and, finally, what is its appropriate treatment?

Before discussing these questions, let me say to you

this: that although, as already indicated, I have rarely seen this complication in typhoid fever, I am very familiar with it in treating typhus fever; for this complication, so rare in the former of these diseases, is not infrequently seen in the latter. I remember an epidemic of typhus which I witnessed in this hospital in 1864 and 1865, when I had a number of these cases under my charge, which (together with some cases previously observed in the Philadelphia Hospital) I made the subject of a clinical paper published in *The American Journal of Medical Sciences*.¹ I now recall that during this term of service I had no less than five cases of parotid swelling after typhus, in a total of fifty cases. I have seen it also as a sequence in other acute fevers, such as erysipelas. Nor does it differ materially when it happens in typhoid from that observed in typhus, except in so far that in the former there is, I think, less tendency to suppuration than in the latter.

Now for a few remarks upon the characteristics of parotid swelling in this disease. At what stage does it appear? Generally, I believe, at the end of the affection and during approaching convalescence. I have personally never met with it in the height of the disease. How was it in this case? The man was distinctly convalescent when he complained of swelling, and marked tumefaction appeared and pain followed. Is it dangerous? How does it affect the prognosis? You will notice here a very curious diversity of opinion; some authorities have maintained that it is rather a favorable sign, but still the majority believe that it is an accident that makes the case a worse one.

I cling to the latter view. From my considerable experience with parotid fluxion in typhus, I have learned to dread it. I have found that these cases were dangerous; nay, I have seen death from it: partly from pressure upon the trachea and interference with respiration and deglutition, and partly as a result of the secondary blood infection from the suppurating gland. Therefore, this complication, whether in typhus or typhoid, makes the case a grave one. My own observation shows that, occurring before full convalescence is instituted, it indicates that the original specific poison is not yet eliminated from the system, and that this poison localizes itself in the parotid gland, usually on one side, sometimes on both.

What is the result of this hardening and inflammation? Very generally — and this is one of its dangers — it leads to profuse suppuration; and unless you give early exit to the pus you have the danger of purulent infection, superadded to the prostrated state of the system from the original disease. Suppuration, then, is one result of this hardening. Occasionally the enlargement subsides slowly; in other cases, again, it may indicate such a profound blood poisoning that the patient perishes from this condition, undoubtedly aided by the pressure upon the upper air-passages.

Before discussing the general plan of treatment, let us inquire what has been done here. The surface over the affected gland was first painted with iodine, but it did no good; the swelling continued, and became more hard and tender. I then gave up the iodine treatment, and resorted to the application of ice in a bladder. This was very grateful to the patient; it reduced the heat, the swelling, and the tension, and for a time the tumor diminished very materially. This ice-treatment was faithfully followed for a few days, until we found that the fluxion of the gland had largely

¹ For January, 1866, pages 1-34.

yielded to the cold applications. They were then discontinued for a day, and now we see the swelling has again increased. This morning we shall resume the ice-bag. Should I find fluctuation occurring, I would reverse the treatment, applying poultices and hot fomentations. As soon as suppurative action is evident the gland should be freely incised.

I have tried in these cases of parotid swelling, both of typhoid and typhus, all kinds of treatment, with a view of preventing abscess, applying nitrate of silver, tincture of iodine, even a blister, but in vain; I have not been able even to reduce the swelling. Perhaps, of all, the blister was the best. But previous failures have led me to try the ice applications, which were so efficient in the preceding case; and thus far I have every reason to be satisfied. In a day or two more of their use here, when the redness has gone, if the swelling does not completely subside, I will apply a blister. In addition to this local treatment, we are taking care of the general system by giving the tincture of the chloride of iron (twenty drops every third hour), and also twelve grains of quinine daily. Four ounces of whisky in milk punch have also been continued since his typhoid-fever attack; but his diet is more liberal than during the fever, although necessarily soft. The treatment is therefore mainly by iron. Should I have occasion to change this, I will resort to the internal administration of iodine, either in the form of Lugol's solution or that of the tincture; but I think that the tincture of the chloride of iron is on the whole the best treatment.

I do not believe that we will have any suppuration here; the application of ice seems to have effectually prevented it.

[The patient's recovery from this date was slow, but uninterrupted. No further involvement of the parotid occurred, and the swelling terminated by resolution.—*REP.*]

ONE THOUSAND DEATHS IN A LIFE INSURANCE COMPANY.

BY JOEL SEAVERN, M. D.

A MUTUAL benefit organization (the Knights of Honor), one of whose objects is cooperative life insurance, which has a membership of nearly sixty thousand adult males in thirty-three of the States of our Union has lately—December 1, 1879—announced its notice of the one thousand and twenty-first death in its ranks. I have given some time to an analysis of the results of its work.

Members are admitted to the order by ballot, after a medical examination, the unfavorable report of a medical examiner excluding an applicant. These medical examiners are chosen by ballot in the various lodges, and are more or less fit for their positions. Many of them have had other experience as examiners for life insurance companies, and are men of skill; some have had no previous experience, but are men of education; and still others have little experience or education. For these reasons much anxiety has been felt by thoughtful members of the order regarding its continued existence, and the perpetuity of an insurance association whose portals are guarded by sentinels so various in efficiency.

It has seemed to me, therefore, interesting to make an inquiry into these deaths, both as regards the section of country where they have occurred and the nature of the causes of death, together with a comparison of the results with other mortuary reports by government or by insurance companies.

With regard to the location where the deaths have occurred, I give a table, the first column of which shows the States in which the order exists; the second column the number of persons in each State belonging to the order December 31, 1878, according to the report of A. J. Cummings, Esq., its chief officer; the third column the whole number of deaths in each State since the order was founded, in 1873; and the last column the ratio of deaths to membership.¹

TABLE OF STATES, MEMBERSHIP, AND DEATHS.

States.	Members.	Deaths.	Ratio.
Michigan.....	2,529	12	1 to every 211
Minnesota.....	351	2	1 to every 176
Connecticut.....	513	3	1 to every 171
Nebraska.....	410	3	1 to every 137
Illinois.....	2,487	21	1 to every 119
South Carolina.....	592	5	1 to every 118
District of Columbia.....	110	1	1 to every 110
West Virginia.....	517	5	1 to every 103
Colorado.....	104	1	1 to every 102
Maine.....	613	6	1 to every 102
Maryland.....	586	6	1 to every 98
Wisconsin.....	1,066	12	1 to every 89
Massachusetts.....	7,149	81	1 to every 88
Iowa.....	598	7	1 to every 85
Kansas.....	849	11	1 to every 77
New York.....	3,412	44	1 to every 77
Pennsylvania.....	3,434	46	1 to every 75
New Hampshire.....	662	9	1 to every 74
Georgia.....	1,585	23	1 to every 69
Rhode Island.....	416	6	1 to every 69
New Jersey.....	586	10	1 to every 59
North Carolina.....	541	10	1 to every 54
Ohio.....	3,810	71	1 to every 53
Texas.....	1,760	34	1 to every 52
Virginia.....	1,311	25	1 to every 52
Alabama.....	740	16	1 to every 46
Missouri.....	1,626	41	1 to every 40
Indiana.....	2,168	55	1 to every 39
Arkansas.....	738	21	1 to every 36
Kentucky.....	4,295	121	1 to every 35
Tennessee.....	4,314	243	1 to every 18
Mississippi.....	792	60	1 to every 13
Vermont.....	Not stated.	2	Unknown.
Total.....	50,672	1,013	—

It should in fairness be stated here that 207 of these deaths were caused by yellow fever, 144 in Tennessee, 41 in Mississippi, 17 in Kentucky, 3 in Arkansas, and 1 each in Alabama and Massachusetts.

If these deaths be omitted it will change the ratio in these States to the following:—

Kentucky.....	1 death to every 41 members.
Mississippi.....	1 death to every 42 members.
Arkansas.....	1 death to every 42 members.
Tennessee.....	1 death to every 44 members.
Alabama.....	1 death to every 49 members.
Massachusetts.....	1 death to every 89 members.

The table shows such results in the extraordinary healthfulness of the order in some States, and its equally unhealthful condition in other similar States, that it would seem of itself to prove that greater care and discrimination had been exercised in admissions in

¹ I have not the full report of the first eight deaths, so that the table covers 1013 cases.

the former, and that the fatality is due to other than climatic influences. Michigan, Minnesota, and Connecticut might have been expected to hold a favorable rank, but one could hardly have believed that South Carolina should have stood better than Colorado, Maine, or Wisconsin, or that Maryland should surpass Massachusetts, New York, and Pennsylvania.

Passing by the matter of localities let us take up the causes of death and their classification, and make a comparison between the results of this thousand cases and other similar reports.

The fact previously alluded to, that some of the medical examiners (who were perhaps in many cases the ones who certified the causes of death) are imperfectly educated men, makes it at times difficult to classify the returns, and arrange the deaths under any system. For instance, we have a death certified to as caused by "congestion of the brain and falling from a building," it not being stated which took place first; one caused by "dysphagia on account of closing the glottis," and we are left to guess whether or no he closed his glottis voluntarily for the purpose of producing dysphagia; one by the following congeries and avalanche of maladies, "inflammation of neck of the bladder, acute bronchitis, pleuro-pneumonia, inflammation of left ear, nephritic trouble, and functional cerebral trouble" (he must originally have been a first-class risk who succumbed only to this torrent of disease); and still another had "organic duodenum of the heart," whatever form of cardiac disease that may be. I allude to these not as a mere matter of diversion, but to show what have been the difficulties of classification.

But arranging them so far as possible according to Dr. Farris's system, as adopted in the registration of Great Britain and that of Massachusetts, we find the results more complimentary to the medical examiners than might have been expected.

For the purposes of this comparison I have taken the deaths from all causes for twenty years in Great Britain, as given in official reports; those for thirty-seven years in Massachusetts, also taken from official reports; a table of 1000 deaths in a New York life insurance company, published by Dr. Buck (chief medical examiner of the company) in the New York *Medical Record* for 1874; and a table of 13,765 deaths made up from English and Scotch life insurance companies, as follows:—

In the Gresham	1,000 lives.
In the Scottish Amicable	773 lives.
In the Scottish Equitable	1,855 lives.
In the Clerks	1,008 lives.
In the Equitable	4,095 lives.
In the Gotha	2,471 lives.
In the Scottish Widows	1,398 lives.
In the Briton	1,165 lives.

13,765 in all.

These statistics are taken from a valuable work on Life Insurance by Dr. Sieveking, of London.

The Knights of Honor encountered in the fall of 1878 a very serious disaster from the prevalence of yellow fever, which disease alone, in 1878 and 1879, up to December 1st, caused two hundred and seven deaths. This of course makes the number of those dying from zymotic diseases very large, and thereby lessens the relative frequency of other causes of death. I have therefore in our comparative view drawn our percentages both with and without the yellow fever cases. The classification results as follows:—

Zymotic diseases	356
Tubercular	117
Nervous system	103
Circulatory system	39
Respiratory organs	116
Digestive organs	82
Urinary and generative	39
Casualties	93
Suicides	30
Cancer	25
Unknown or unclassified	13
Total	1,013

Taking, then, these figures and those previously referred to from other sources, we have prepared the following table. It is obvious, however, that the yellow-fever factor in the tables throws a certain amount of obscurity upon the matter, and to some extent vitiates the comparison; because, on the one hand, including these cases we find the deaths from zymotic diseases unduly large, whereas in excluding them the number of zymotic deaths is too small, and we leave out of sight those persons among them who might probably have died of other diseases.

COMPARISON OF DEATHS.

The first column is computed from 9,124,696 deaths in Great Britain; the second from 828,484 in Massachusetts; the third from 13,765 in English and Scotch companies; the fourth from 1000 in the New York company; the fifth from 1013 in the Knights of Honor, including yellow-fever cases; and the sixth of 806 in the Knights of Honor, omitting yellow-fever cases:—

	Great Brit- ain.	Massachu- setts.	English and Scotch Life Companies.	New York Life Compa- ny.	K. of H., in- clud- ing yellow fever.	K. of H., ex- clud- ing yellow fever.
	Percent.	Percent.	Percent.	Percent.	Percent.	Percent.
Zymotic disease.....	22	23	11	25	18	13
Tubercular disease.....	15	12	13	27	12	15
Nervous system.....	12	9	18	13	10	13
Circulatory system.....	4	3	7	6	4	5
Respiratory organs.....	15	7	12	9	12	14
Digestive organs.....	9	4	10	10	8	10
Urinary and gener- ative organs.....	1	1	3	4	4	5
Casualties.....	-	4	10	6	9	10
Suicides.....	0.5	0.4	-	2	3	4
Cancer.....	-	1.5	-	12	2	3
Unknown or un- classified.....	-	-	9	1	1	1

Time and space will not allow us to enter into a very careful analysis of the above table, but a few general facts are indicated by it. First, that as regards zymotic disease the order has been unfortunate, but that this misfortune has arisen from the fatal prevalence of one disease, yellow fever, that could hardly have been foreseen. Next, that as to tubercular diseases, the order has been fortunate, if we use that expression, or that the portals of its entrance have been guarded better than we feared. Diseases of the brain and nervous system have also been less frequent than in the other companies, as well as diseases of the heart and circulation. The two classes (like the tubercular) are the ones which are most preventable by a careful selection of lives, and the result shown is therefore complimentary to the medical men in the order.

Acute diseases of the respiratory organs show a rather large percentage, and the suspicion may arise that some deaths have been certified to as caused by acute disease which were really owing to tuberculosis; still, this deception would be just as likely to occur

in other life companies, since their medical examiners are probably as anxious to shield themselves from a suspicion of having admitted impaired risks into their ranks as those of the Knights of Honor. Furthermore, if we add in each column the percentage of tubercular and respiratory diseases it will still appear that the comparison is favorable to the Knights.

The results of diseases of the digestive organs are a little better than those of the other reports; those of the urinary and generative organs not quite as good; whilst the percentage from casualties and suicides is unusually large.

I have made special note of the cases of cancer, because in some similar organizations great importance has been attached to this as a cause of death, by refusing admission to persons who near relatives have had any form of it. It appears that even including one or two doubtful cases, such as stricture of the œsophagus, which may or may not have been cancerous, there are but twenty-five in all the thousand and thirteen cases, which would tend to show that this disease is not a very important factor in life insurance; and I find it reported in the *Medical Record* of 1874 that of the twenty-three cases occurring in twenty-four years' experience of a life insurance company only one seemed to have been of hereditary origin, and that in this case it had existed only in one other member of the family, a sister. The two and a half per cent. which cancer shows in the Knights of Honor columns is a trifle more than in the Massachusetts report, or that of the New York Company, these being the only ones where it can be traced out.

Let us scrutinize more strictly now the cases of tubercular disease, one hundred and seventeen in all, which number, it will be remembered, was *not* unduly large. It will be observed, too, that though there were some who died within a comparatively short time after joining the association (four died within six months) there were but twenty-six who died within a year. The shortest time was that of a member from Missouri, who lived but four months after admission, and one each from Kansas, New Jersey, and Wisconsin, who died in five months; the longest that of one who lived over five years from the date of his entrance. The average time was a little over a year and eleven months, which would indicate that a reasonable amount of skill was used in the preliminary examinations.

The following table shows the number of deaths in each State from tubercular disease; Maine, Vermont, Connecticut, Maryland, Texas, Colorado, Minnesota, and Nebraska having had none:—

TABLE OF DEATHS BY TUBERCULAR DISEASE BY STATES.

Kentucky.....	21	New York.....	2
Massachusetts.....	13	Georgia.....	2
Ohio.....	12	South Carolina.....	2
Tennessee.....	11	Rhode Island.....	2
Indiana.....	11	Michigan.....	2
Missouri.....	6	Kansas.....	1
Illinois.....	6	Alabama.....	1
Virginia.....	6	Arkansas.....	1
Pennsylvania.....	5	Iowa.....	1
New Hampshire.....	5	Mississippi.....	1
New Jersey.....	3	North Carolina.....	1
Wisconsin.....	3	West Virginia.....	1

As it will be remembered that the number of members in these different States varies greatly, our next table shows the proportion of these deaths to the membership.

TABLE SHOWING THE PROPORTION OF TUBERCULAR DEATHS TO MEMBERSHIP BY STATES.

New York.....	1 death to 1706 members.
Michigan.....	1 death to 1264 members.
Kansas.....	1 death to 849 members.
Georgia.....	1 death to 793 members.
Mississippi.....	1 death to 792 members.
Arkansas.....	1 death to 758 members.
Alabama.....	1 death to 740 members.
Pennsylvania.....	1 death to 691 members.
Iowa.....	1 death to 595 members.
Massachusetts.....	1 death to 549 members.
North Carolina.....	1 death to 541 members.
West Virginia.....	1 death to 517 members.
Illinois.....	1 death to 414 members.
Tennessee.....	1 death to 392 members.
Wisconsin.....	1 death to 355 members.
Ohio.....	1 death to 317 members.
South Carolina.....	1 death to 296 members.
Missouri.....	1 death to 271 members.
New Hampshire.....	1 death to 221 members.
Virginia.....	1 death to 218 members.
Rhode Island.....	1 death to 208 members.
Kentucky.....	1 death to 203 members.
Indiana.....	1 death to 197 members.
New Jersey.....	1 death to 195 members.

In all New England there were 9353 members and 18 tubercular deaths, or a ratio of 1 to 520.

Still another question is interesting, which is the ratio of consumptive deaths to all other deaths in the association in the several States:—

PERCENTAGE OF TUBERCULAR DEATHS TO ALL DEATHS IN THE SEVERAL STATES.

States.	Deaths.	Tubercular.	Per Cent.
South Carolina.....	5	2	40
Rhode Island.....	6	2	33
New Hampshire.....	9	3	33
New Jersey.....	10	3	30
Illinois.....	21	6	29
Wisconsin.....	12	3	25
Virginia.....	25	6	24
Indiana.....	55	11	20
West Virginia.....	5	1	20
Kentucky.....	121	21	17
Ohio.....	71	12	17
Massachusetts.....	81	13	16
Michigan.....	12	2	16
Missouri.....	41	6	15
Iowa.....	7	1	14
Pennsylvania.....	46	5	11
North Carolina.....	10	1	10
Kansas.....	11	1	9
Georgia.....	23	2	9
Alabama.....	16	1	6
Arkansas.....	21	1	5
New York.....	44	2	5
Tennessee.....	243	11	5
Mississippi.....	60	1	2

One fact is of course made obvious by both these tables, which is that the number of deaths is too small to draw important deductions from; yet we cannot but be struck by the favorable showing which the State of New York presents, having but two deaths from phthisis in a membership of over 3000 and a mortality list of 41.

Michigan, Kansas, Pennsylvania, Iowa, and Massachusetts, as Northern States, show records which need not fear reproach, whilst New Jersey, New Hampshire, Indiana, Ohio, and other Western States have been less fortunate, and the States of South Carolina, Virginia, and Kentucky excite our surprise at the large number of consumptives in their favored climates.

The apparently good results in Tennessee and Mis-

Mississippi are evidently owing more to the large number of deaths from yellow fever than the small number from phthisis.

Leaving here this subject of tubercular disease, of which much more might be said, let us conclude by a brief investigation of the deaths by casualties and suicides.

These two are thus associated because there is no doubt in fact a connection between them, some deaths being attributed to accident which may have been suicidal, whilst there is, of course, a possibility that some may have been purely accidental which were considered self-inflicted. Many of the former are reported in such a way as to lead one involuntarily to at least think of suicide: thus the one caused by "strangulation," those by "poison," those by "drowning," and by being "shot."

The following table gives a list of the casualties which are certified to as the causes of the deaths of ninety-three members of the order:—

Railroad accidents.....	20
Falls (from buildings, etc.).....	15
Drowned.....	12
Shot.....	7
Explosions (of boilers, etc.).....	7
Stroke.....	6
Poisoned (by overdose of medicine, etc.).....	6
Crushed (by falling objects, etc.).....	6
Murdered.....	4
Killed by horses (runaways, etc.).....	4
Circular saw.....	1
Lightning.....	1
Strangulation.....	1
Suffocated by gas.....	1
Accidents (kind not stated).....	2
Total.....	93

As regards suicides, the large number of them has led to the apprehension that some persons may have joined the order for the purpose of committing suicide, so as to leave the insurance to their families; and an interesting question of casuistry has been raised on this point, whether such an action should be applauded as a sacrifice of life and a heroic deed for the benefit of those dependent on them, or be denounced as a fraud upon the insuring company.

It is, however, evident in most of the thirty cases reported in our list that these persons did not join the order with that intention in view, as they continued their membership and paid their dues and assessments for a considerable length of time before the fatal act,—this time averaging over a year and a half,—only one killing himself in fourteen days after joining, one other in less than two months, and but six in less than a year. The total time of the thirty members sums up to forty-five years and two months.

This concludes our inquiry into the results of 1013 deaths in cooperative life insurance, in an association where the medical examinations have been conducted by average men, chosen by a popular vote, probably in some instances more for their social qualities than their scientific attainments. I think the result of the inquiry speaks well for the ordinary medical practitioner of our country.

—The Connecticut legislature has recently passed an act authorizing the State Board of Health to prepare rules and regulations for the examination of railroad employees in regard to color-blindness. Every company in the State is obliged to hold such examinations on or before the 1st of October.

CASES OF OVARIOTOMY.

BY HENRY CLARKE, M. D., WORCESTER.

THE operation of ovariotomy has become of late so safe in the hands of a few skillful surgeons that it behooves every one who undertakes it to study well his failures, and see if they have not resulted from some fault of his own.

It would almost seem that such must be the case if we take the recent results of Dr. Keith and Mr. Wells for our standard. Yet many speak lightly of the operation, as one to be undertaken by any surgeon. Sometimes, indeed, it is a simple operation, but at other times quite the reverse. Certain it is that no surgeon has as yet had any great success either in simple or in difficult cases, except through thorough preparation, painstaking care, and unwearied devotion.

I cannot boast of any large experience, but I have had enough to suggest these introductory remarks, and I believe they will command the approbation of all operators of greater experience than my own.

After having had six successive recoveries from ovariotomy, I have had one case which resulted fatally. I will note only a few facts of interest in connection with the successful ones before passing to a fuller report of the last one, which is the chief object of this paper.

Of these six cases three were treated without the use of antiseptics, one with partial antiseptic treatment, and in two the operation was done under the carbolic spray. All were operated upon in private houses, but two of them were in localities with poor sanitary surroundings.

In five of the cases the pedicle was tied with silk or linen ligatures and dropped into the abdomen, and the abdominal opening was closed by sutures throughout its whole extent. In one only was the pedicle brought out and fastened in the lower angle of the wound, but this caused so much discomfort by dragging upon the pelvic organs that it was allowed to drop into the pelvis at the beginning of the second day.

In the first case the woman was delivered of her first child within a twelvemonth from the date of the operation.

In the fourth case there was general peritonitis at the time of the operation, resulting from a rupture of one of the cysts. The sixth case was a girl of fourteen, who weighed only sixty-five pounds. The uterus was undeveloped, and there were no indications of approaching puberty. The tumor was a dermoid cyst, which contained fat pieces of bone, resembling fragments of the skull, teeth, and hair. The girl made a rapid recovery, and was taken to drive within three weeks from the time of the operation by Dr. Leonard Wheeler, who had had the principal care of her. In the other cases there was nothing worthy of special mention.

This brings me to my last case, which terminated fatally, and I shall report it at greater length. The two special points of interest in it which will be particularly considered are the size of the tumor and the sloughing of the stump.

Miss C., aged forty-two, came under my observation in the latter part of November, 1879. The tumor was judged to be a monocus, and was very large. She had been advised by a distinguished ovariologist, two years before, to submit to an operation, but for several reasons she had postponed it. According to her

statement, the tumor had enlarged more rapidly during the two preceding months than at any other corresponding period of time since its discovery, about seven years previous. A comfortable apartment was procured, the patient antiseptically prepared, and the operation was performed December 1, 1879. I was assisted by Drs. Wood, Marble, Wheeler, Rich, Hammond, and Bull. A Colman and Shurtliff spray producer and a smaller steam atomizer were intrusted to an experienced assistant. Ether was administered, an incision three inches long made through the linea alba, and the cyst tapped with a curved trocar. The large sac, together with a mass of small cysts attached to it, was drawn out through the opening, no fluid escaping into the abdominal cavity. The pedicle, which was unusually short and thick, was tied in halves with carbolized silk, and then one half of the ligature was made to encircle the whole, and firmly tied.

After cutting away the walls of the cyst there was some oozing of blood from the stump, in consequence of which it was lightly cauterized by Paquin's thermo-cautery. There was very little bleeding from any source, and there was but a small quantity of bloody serum to be sponged from the pelvis. In fact, I never saw so dry an operation. As the pedicle was drawn up for a final examination before tying the abdominal sutures a little bleeding occurred, and while I held it between my thumb and fingers an assistant passed another ligature around it and tied it as tightly as possible, and, as I now fear, too tightly.

The intestines and omentum did not descend to fill up the pelvic cavity as much as is usual, although they were pulled down for that purpose. This was shown by a quantity of air issuing with a gurgling sound from the lower part of the wound when pressure was made laterally upon the abdomen before tying the last suture. I have omitted to state that there was an interruption of the spray, which occurred before the sutures were applied. The interruption was complete for two or three minutes, the tube of the smaller atomizer becoming obstructed while the larger machine was being put in order. The wound was, however, immediately covered by flannel wrung out in hot carbolized water. The antiseptic dressing, after the method of Keith, was applied, and the patient put to bed at one o'clock in a satisfactory condition.

A careful record of the condition of the patient was made at each subsequent visit, but I will not give unnecessary details.

The first four days were passed very comfortably. The highest temperature was 101.5° F., and the pulse varied from 100 to 115. No vomiting. Flatus passed by rectum on the second day. No distention or tenderness of bowels. Took a little nourishment by the mouth, but more by the use of nutritive enemata.

Vomited for the first time on the fifth day, and temperature rose to 102° F., and pulse to 120. Vomiting ceased, and on the sixth day temperature fell to 100° F., and pulse to 110. Sutures removed on this day. Wound apparently united, except at one point between the two upper stitches, where some pus escaped. The bowels were moved by an enema of spearmint tea on the seventh day. Some nausea, but no vomiting, and temperature and pulse as on previous day. Took a little nourishment by the mouth. Nutritive and stimulating injections continued.

Eighth day. Moistenance good; temperature 99° F.; pulse 98; skin moist, as it has been from the first day;

no pain and little tenderness of bowels; wound discharged more pus.

Ninth day. Temperature rose to 102° F., pulse to 125; vomited frequently and distressingly; stomach distended by gas.

Tenth day. Vomiting continues; transverse and descending colon much swollen and hard; stomach less so; bowels flat; pulse feeble at 125.

Eleventh day. As upon previous day; a large injection of spearmint tea was followed by a copious defection, and accompanied by a disappearance of the distention of colon, which was so hard as to suggest an accumulation of hardened feces. But this was not the case.

The patient sank rapidly from this, time and died in the early part of the twelfth day. It will be observed that there was very little pain, no marked tenderness, and no tympanitis of abdomen at any time.

Autopsy twenty hours after death, in which I was assisted by Dr. Wheeler. Abdomen but little swollen. The wound was found united upon its peritoneal surface, except at one small point near the lower angle. The pelvis contained about half a pint of thin purulent matter with a slightly pinkish tinge. Pedicle had sloughed up to the point of the ligature.

The peritoneal membrane was granular and reddened, and adhesions were quite extensive. Some strong, firm bands crossed and tied down portions of the transverse and descending colon. It was evident that these strong bands across the colon were what caused the accumulation already noted. No other morbid changes were observed.

Here we have a case of peritonitis of an asthenic type following ovariectomy performed under the spray. What was the cause of this unfortunate result?

Had the size of the tumor any causal relation to it? The weight was fifty-five pounds, and the intestines were pushed upwards, as were also the thoracic organs.

Schroeder, in his report of his second series of fifty ovariectomies, speaks of the increased danger in cases of ovarian cysts of unusual size. Upon the removal of a very large tumor, there is a redundancy of tissues forming the abdominal walls. The greater displacement of the intestines causes a cavity to be left in the pelvis, in which air may become inclosed. To avoid this danger, he packs the pelvis by drawing down the intestines and the omentum over them, and then pressing the abdominal parietes well in, before closing the wound. In this way the air is expelled.

It will be observed that the very condition of things spoken of by Schroeder existed in this case. Might not some air containing septic germs have remained in the abdominal cavity, and have caused the inflammation and suppuration? It should be remembered in this connection that a slight interruption in the carbolic spray occurred while dressing the wound, and before the sutures were tied.

Another question which has suggested itself to me is whether the pedicle could have been so tightly tied as to cause it to slough. As previously stated, it was tied twice, and the last time the ligature, which was of carbolized silk, was drawn very firmly by the strong hands of one of my assistants. Could it have been drawn too tightly, and is this one of the dangers to be guarded against? No such warning is given in any of the systematic treatises on ovariectomy.

The reasons that the stump does not slough are said

to be the following: First, an exudation of lymph forms over and around the ligature, which organizes and carries blood to the distal end. Secondly, the peritoneal membrane on either side of the ligature may bulge over the deep, narrow gutter made by the constriction, and unite, and thus give life to the part from which the circulation of blood has been cut off. Now, if these are the only means by which nature preserves the life of the stump, there can be no danger of drawing a small ligature too tightly, because the deeper it sinks the more certainly will the little gutter be bridged over by the bulging of the parts on either side.

That these processes do occur cannot be disputed; but do they always occur soon enough to prevent sloughing when the constriction is so great as to cut off all circulation from the distal end? I find one authority who answers this inquiry in the negative. I refer to an article by Dr. Alban Doran, published in the twelfth volume of Saint Bartholomew's Hospital Reports. Dr. Doran describes the post-mortem appearances of ten cases which had been operated on by different surgeons in the Samaritan's Hospital. In only a small minority of these cases could death be attributed to the intra-peritoneal treatment of the pedicle. The presence of a firm coagulum upon the end of the pedicle he considers a good indication, as showing that it had not been tied so tightly as to cause sloughing, and yet tight enough to prevent hemorrhage. He says the pedicle sometimes partially sloughs in consequence of being too tightly tied, and warns surgeons against this danger, which he considers a greater one than the possibility of hemorrhage from being tied too loosely.

It seems to me that here is a source of danger which is not duly appreciated by most operators, and I cannot help feeling that in the case here reported the second ligature was the principal cause of the extensive sloughing of the stump.

It is of course impossible to know certainly whether one of the above-mentioned conditions, or all of them combined, produced the peritonitis which was found to exist, but the points which I have raised in this case will not, I hope, be considered unworthy of the prominence I have given to them.

Reports of Societies.

PROCEEDINGS OF THE BOSTON SOCIETY FOR MEDICAL OBSERVATION.

FREDERICK C. SHATTUCK, M. D., SECRETARY.

JANUARY 5, 1880. DR. BUSH read a paper on

A CASE OF ABORTION, WITH INSTRUMENTAL DELIVERY, AND DEATH ON THE FOURTH DAY FOLLOWING.

A woman thirty years of age miscarried during the fourth month, after prolonged use of the sewing-machine and accidental violence. The fetus was delivered with instruments, on account of the exhausted condition of the woman, who had a feeble pulse and irregular pains, causing great agony. The vagina was hot and tender, abdominal tenderness was marked, and as her condition was growing more alarming it was thought best to empty the uterus. The placenta was adherent and only partially removed, the reporter thinking there would be less risk in leaving the small

portion than in further manipulation. Four days later she died from septicæmia. In another case he should remove the fetus if possible, using the finger as a curette, and, if not successful in this, plug.

DR. INGALLS spoke of his great good fortune in never having had a case of puerperal septicæmia in a long obstetric practice. In cases of abortion he has sometimes left the placenta to nature, but has often removed the ovum with the finger, which he considers the very best instrument for the purpose. Within a few years he has in several instances introduced the whole hand into the vagina, thus having the thumb and forefinger with which to work. In one case, even after the introduction of the hand, he could not remove the placenta, and the woman had a foul, fluid, slate-colored discharge for six or seven weeks after this; but it then ceased, and she has been in perfect health ever since. This is the longest period which has come under his observation, the time generally varying between a day or so and two or three weeks. The treatment of these cases is certainly a very important and embarrassing point in obstetric practice, and it is often difficult to make the patient realize the importance of rest and quiet, she being very apt to think herself better than she is.

DR. C. E. INCHES said that in his experience plugging is the best treatment, and that he has become convinced of the truth of Dr. Meigs's statement that the blood dissects away the membranes. He always plugs with ordinary cotton, and after eighteen hours or so finds the membranes behind the plug.

SUBNORMAL TEMPERATURE.

DR. BRADFORD reported the case of a child who, after excision of the elbow by Dr. Ingalls some time before, was eating and sleeping well, and had no unfavorable symptom, but whose temperature was found to be 95° F. It being thought that there must be some mistake, other thermometers were used, one of them tested and vouched for at Kew not long ago, but all registered alike 95° F. The next day the temperature was 96° F., the next 97° F., and since then it has been normal, there being no other indication of change in the condition of the child.

DR. INGALLS remarked that it is very possible subnormal temperatures would be oftener met with if it were made an invariable rule to shake the index well below the lowest markings before using the instrument.

DR. STONE related the case of a child recovering from bronchitis whose father had bought a clinical thermometer, and, finding the temperature 96° F., went to Dr. Stone in alarm. He found the child asleep, bathed in perspiration, and verified the thermometric observation; the next morning the temperature was normal.

DIPHTHERIA, WITH LONG PERIOD OF INCUBATION.

JANUARY 19, 1880. DR. WELLS reported the case. A governess living in the family of a late New York surgeon had nursed, several weeks previously, two of her young charges through attacks of diphtheria. Two weeks after they were well enough to go out-of-doors they were taken to a summer resort on the coast of Maine. A few days after their arrival, and two and a half weeks after they had begun to go out, the governess, who had not been well in the mean time, was attacked with what the family supposed to be an ordinary sore throat. It proved, however, to be a well-marked case of diphtheria, from which she event-

ually recovered. Dr. Wells was led to connect her attack with her exposure, because it could not be accounted for in any other way. There had never been a case of the disease in town: the sanitary arrangements of the house were excellent; the drinking water, ice, milk, etc., pure; and so long a period of incubation, though unusual, is not beyond the bounds of possibility.

A paper entitled

CASES OF EMPYEMA

was read by DR. A. T. CABOT. He reported three cases, one of which was treated antiseptically, with rapid recovery, and invited discussion, particularly on the following points:—

(1.) How useful is aspiration in empyema, when should it be done, and how often should it be repeated before resorting to the more radical operation?

(2.) How important is the strict observance of antiseptic precautions in making a free opening?

(3.) What are the relative advantages of the different methods of treating the opening?

DR. MINOT strongly advocated a free opening whenever the consent of the friends can be obtained. Its necessity is unquestioned in adults, and in children, though aspiration alone is not infrequently successful, recovery is more sure and rapid after incision. He has often tied a condom to the end of the drainage tube in children to receive the discharge.

DR. PORTER said that empyema should be treated like any other abscess, and opened. As yet he has never used the antiseptic method in this operation, but means to do so in future. Lister says that when his method is rigidly carried out there never is any secretion of pus, but only an abundant serous discharge, requiring thorough drainage and a change of the dressing once during the first twenty-four hours, and then daily in an adult. In antiseptic surgery in general it is important to make sure that the spray does not give out before the operation and dressing are completed.

DR. TARBELL also expressed his intention to employ Lister's method in future in these cases. In some of his cases, in which objection was made by the patient or the friends to the knife, he had used a very large trocar, and introduced the drainage tube through the canula, then withdrawing the latter.

The reader inquired whether Dr. Tarbell had ever seen any trouble arise in these cases from the fibrinous clots which were retained in the chest.

DR. TARBELL answered in the negative, and then alluded to the unwillingness of some physicians to etherize a patient in operating for empyema. He always uses the anæsthetic, seeing no reason why he should not seek to avoid the pain of that as well as of any other operation. The treatment by frequent aspiration cannot be regarded as justifiable nowadays.

DR. ROTCH inquired as to the danger of carbolic-acid poisoning from washing out the pleural cavity with a solution of that substance. Several gentlemen stated that they had neither seen nor read of such an occurrence, and the reader said that his idea in washing out the cavity was simply to remove the coagulated fibrin,—not to render the cavity aseptic, which it is already if the proper precautions have been observed.

DR. BOWDITCH expressed himself as deeply interested in the discussion, and said that it is now almost exactly thirty years since Dr. Wyman first drew off

fluid from the chest. The patient was a woman, sick three weeks with a large effusion and terrible orthopnea. Dr. Wyman called the late Dr. Homans in consultation, and proposed tapping with an exploring trocar and canula and a suction pump. Dr. Homans thought it better not to interfere, but Dr. Wyman advocated the experiment so strongly that Dr. Homans said he would talk with his professional friends in Boston and return in the morning. When they met again he said, "Wyman, everybody is opposed to the operation, but, as the woman will die unless relieved of her dyspnoea, perhaps it is allowable to operate." Dr. Wyman immediately tapped, with prompt and entire relief, and in three weeks the woman was well. Gerhard, of Philadelphia, after the operation had been done in Boston, said, in reply to a question from Dr. Bowditch, that he would as soon put a bullet through the chest. Dr. Bowditch first operated in Boston because no one else would do so, but, owing to his want of surgical skill and experience, was in great fear and trembling before his first operation, and enjoined upon his friend, a young surgeon who accompanied him by special request, to take the instruments from his hand and complete the operation should he (Dr. Bowditch) be unable to do so. A wonderful advance has been made in the treatment of these cases during the last twenty years, but the tendency now is to make an opening under almost any circumstances, without regard to the age of the patient or the duration of the disease,—factors which should not be left out of account. It is often very difficult to decide whether to aspirate or to make a free opening, and he has seen cases run down under either method when the disease was of long standing.

DR. ELLIS expressed the opinion that aspiration, if resorted to, should be repeated as often as pus could be found, so as to leave as small a cavity and keep the lung as much expanded as possible.

DR. T. B. CURTIS said that with Lister success is apparently the rule, and neither in spinal abscess nor empyema is any pus secreted after the opening is made. He applies gauze from the axilla to the pelvis to insure against the entrance of air, and he never gets carbolic-acid poisoning, because he never washes out the pleural cavity; indeed, he seems to disapprove strongly of such a procedure.

DR. KNIGHT remarked that it is evident that little pus can be absorbed; if it were possible to get our trocar into the lowest part of the chest and remove the whole accumulation, we should probably succeed oftener in curing by aspiration. The annals of the Charité Hospital in Berlin during the last eight years illustrate well the change which has come about in the treatment of pleuritic effusions. In 1871 Traube and Fraentzel were beginning to take an interest in aspiration. The former inquired of the speaker, who was at that time at Berlin, as to Dr. Bowditch's results, got a pump, and convinced himself that there is no danger in the procedure. Their apparatus is now first-rate, and they have of late opened empyemata successfully, according to Lister's method. The point selected by most Americans for puncture is low in the back, but the speaker thinks it better to tap in the fifth inter-space between the axillary and the mammillary lines, as is done in Germany, for the reason that the fibrin naturally gravitates to the lower and posterior portion of the chest, and a "dry tap" is thus more likely to occur if the needle is plunged into that part.

DR. ELLIS said that he has now for a number of

years been in the habit of puncturing just in front of the edge of the latissimus dorsi muscle on either side of the chest.

DR. MIXOT alluded to the remarkable fact that spontaneous openings always take place high up, — in the second or third interspace.

DR. CHADWICK related a very early mention of the evacuation of empyema by incision in New England, which he had lately run across in the account of a voyage in 1662, by Felix Christian Spöri, of Zürich, surgeon. The author speaks of the fog rising, February 12, 1662, and revealing Cape Cod; the vessel's course was turned north, toward Cape St. Anne, which soon came in sight. They then steered into the harbor, and cast anchor near Read Island, within view of the governor's house. A small boat immediately came along-side, with a servant of the governor, who inquired whether there was a surgeon on board. On learning that there was, he requested Dr. Spöri to accompany him ashore, where the son of the governor lay in a very low condition. He found the boy extremely ill, with an elevated point between the third and fourth ribs, and other signs which convinced him that the disease had started as a pleurisy, but, from lack of proper remedies, had turned into empyema. On advising the parents that death must speedily supervene unless the pus was evacuated, the doctor was requested to operate, and did so the next day in the presence of a large number of astonished spectators. Two pounds of offensive pus escaped from the incision, which the doctor then plugged with lint to prevent too great drainage, whereby the patient might lose his life. So immediate was the relief that the patient said he felt better than he had from the twenty purges and thirty clysters which had previously been administered. The same evening and the following days the pus was drawn off, the opening enlarged, and the cavity cleansed by injections. In three weeks the patient was able to return to his business. The doctor's fame spread throughout the neighboring country, so that many persons came to consult him. For this reason he wished to establish himself permanently in practice, but was not allowed to do so by the captain of the Black Horse.

CHRONIC RHEUMATIC ARTHRITIS AND FIBRINOUS RENAL CALCULI.

DR. ARNOLD reported the case and showed the right hip and ankle joints and the kidneys. A single man of forty-five never had had acute rheumatism, but began as a school-boy to suffer from pain and stiffness in his joints, which increased gradually, and disabled him completely by the time he was twenty-five. Three or four months ago nausea and vomiting appeared, and his strength failed more rapidly. One month ago large quantities of pus began to pass with his urine, and continued to do so till his death; about ten days ago a number of small black bodies were voided in the urine, according to the description of his attendant precisely similar in character to those found in the kidneys at the autopsy. Death was rather sudden and unexpected. At the autopsy nothing remarkable was found about the internal organs except the kidneys, which were much atrophied, especially in the cortical portions, and contained numerous cysts of varying size. The contents of some of these cysts was clear fluid, of others blood, and of others again pus, mixed with which, especially in the right kidney, many of the cavities contained also large numbers of dark-colored bodies,

about the size of a millet seed. The pelvis, the lining membrane of which was dark and injected, contained masses of these bodies as large as a robin's egg, easily broken down, and with a slightly gritty feel. The ureters were generally dilated to at least twice the normal size, and the mucous membrane showed marked evidence of chronic inflammation. One of the dark masses from the pelvis of the kidney was sent to Professor Wood, who reported that it was an example of the so-called fibrinous calculus or blood concretion.

TUMOR OF THE CEREBELLUM.

DR. WEBBER reported the case and showed the specimen.

T. S., aged fourteen years, entered the City Hospital December 13th, and stated that three years ago he received a severe flogging at school, and the back of his head was forcibly bumped several times against the floor; the teacher also struck him several blows in the pit of the stomach, which caused him to vomit. He was laid up in bed, unable to go to school for two months, having severe headache and some vomiting.

Soon after getting about he noticed that while going down-stairs he was troubled with dizziness, and has been thus troubled ever since. He has had more or less headache every day since, the pain being located in the back part of his head, below the occipital protuberance. He has felt sleepy much of the time. There has been no trouble with speech or hearing. Vision began to fail nine months ago.

Since last winter he has had six attacks of convulsions; four of these occurred in the night while in bed, two immediately after breakfast. During these attacks, which last ten or fifteen minutes, he is paralyzed and cannot move, vomits, cannot speak intelligibly, does not bite his tongue, is unconscious. When the attack has occurred during the day he has had warning of its approach by a numb feeling beginning in the left side of his head, gradually extending over the whole of his body. Has slept after each attack, and has trouble in walking, from weakness, for half a day. He has had numbness of left half of his head and tongue, and occasionally prickling sensation in left side of his tongue, without the severer convulsion.

On examination a peculiar impairment of speech was noticed; some words were uttered slowly, with an evident effort, not stuttering. His gait was unsteady; he walked with legs far apart, bringing the left foot down more heavily than the right. With the eyes shut he stood steadily, but the unsteadiness in walking was still more marked. Sensation was impaired in the left leg and right hand; in the face it was about the same on both sides. There was trouble with vision, and he could not read well. Dr. Williams examined the eyes and found marked atrophy of both discs.

While in the hospital he had two severe attacks, similar to those described above, and several of the *petit mal*.

On December 18th he was as well as usual, or even brighter; there was no complaint in the evening of any increased discomfort. On the following morning he was found dead in bed, the clothes not disturbed, as if he had died quietly without any struggle.

Autopsy, 3.30 p. m. Brain only was examined. There were a few spots of increased opacity of the pia mater over vertex. Convolutions universally flattened. The ventricles contained a large amount of serum, twelve to fifteen ounces, much of which was lost and not

measured. On the under surface of the cerebellum in the median line, between that organ and the medulla oblongata, extending a little farther to the left than to the right, was a tumor; this involved both lobes of the cerebellum, and measured about three inches transversely. The medulla oblongata was much compressed and flattened. The tumor contained five cysts: two of which were very large, and two others very small; a large cyst projected anteriorly from above the cerebellum below the corpora quadrigemina. Several of the nerves arising from the medulla were thinned, and less white than usual.

The peculiarities of this case are the great freedom from headache during the stay in the hospital, — it was learned after death that headache had previously been severe, — and the small amount of motor and sensory disturbance, notwithstanding the long duration of the case and the size of the tumor: the incoördination was very much less than I have seen in cases where there was a smaller tumor; the general muscular weakness was comparatively slight; there was also little or no mental disturbance. The slow growth of the tumor will explain these peculiarities, the brain adapting itself to the changing relations; indeed, it is quite possible that the tumor had ceased to grow, and the cessation of headache would favor such a supposition. Death was probably caused by a sudden effusion into the ventricles, increasing the pressure beyond the limits at which the nerve centres could act. Perhaps the medulla oblongata was suddenly subjected to a pressure which paralyzed the vital centres contained therein.

Owing to the slight amount of headache, as it was understood, and the slight motor, sensory, and intellectual disturbance in comparison with the length of time since the commencement of the symptoms, a tumor was thought to be less probable than an abscess or chronic thickening of the membranes.

LOCALIZED SUPPURATIVE MENINGITIS AND SOFTENING WITHOUT LOCALIZED PARALYSIS.

DR. J. J. PUTNAM showed a hemisphere of the brain of a child who had died at the Massachusetts Infant Asylum, sent him by Dr. Call, who had charge of the case. The clinical history as reported to him was in brief as follows: Flora —, five months old, was a delicate child, but not distinctly sick till Christmas, 1879. She then lost her appetite, was restless, feverish at times, and the anterior fontanelle grew more tense. January 4th she became unconscious, with strongly contracted pupils, muscular twitching of the right leg, and tonic spasm of the right side of the face and the right arm. January 6th she died. On autopsy marked suppurative meningitis of the whole parietal and posterior part of the frontal region on the left side was found; the vessels of the pia were ensheathed in a thick layer of pus, and the membrane itself was greatly thickened, both at the lower extremity of the fissure of Sylvius and at the upper extremity of both transverse convolutions. At the upper extremity of the right transverse convolution the thickening had obstructed the circulation, and given rise to red softening of the cortex and white substance immediately beneath it.

Dr. Putnam remarked that if the patient had been an adult the localized softening would probably have given rise to localized paralysis, and that the specimen was also of interest in that it showed so well the distribution of the meningeal vessels.

FEBRUARY 2, 1880. A paper was read by DR. CHADWICK on the

HOT RECTAL DOUCHE,

and reserved for publication. The reader was led to employ this method of treatment in gynaecological practice as a substitute for the vaginal douche, which entails so much trouble that in many cases it cannot be, or is not, efficiently employed. The rectal douche is far more easily used, and cases were cited showing its efficacy in peri-uterine inflammation after the more active symptoms have subsided. He had also found it of great service in several cases of chronic diarrhoea and dysentery.

DR. ELLIS inquired how far the water penetrates. The reader replied that he has often heard and felt it gurgling in the right iliac region, the patient lying on the left side. — DR. ELLIS said that he found it difficult to understand how a quart of water — the maximum amount used by the reader — can find its way so far. The quantity is not sufficient to distend the whole large intestine, and under these circumstances it is only by reversed peristaltic action that the force of gravity can be overcome. The reader observed that perhaps we do not estimate retrostalsis at its proper value. In a case of ovariotomy operated on by him, during a period of five days absolutely no food was given by the mouth; enemas of beef tea were, however, administered, and at the end of the above-named period the patient vomited stercoraceous matter. This was examined microscopically by Dr. Cutler, and beef fibre was found. After the injection of a certain amount of water the patient has a desire to void it; but this soon passes off if the current be stopped for a short time, and the injection can then be continued. The fluid usually passes upwards out of the rectum, as he had convinced himself by keeping a finger in the vagina in several cases while giving the douche.

DR. DWIGHT thought the discussion as to how far the fluid penetrates of scientific rather than practical interest, and doubted whether it often goes beyond the sigmoid flexure.

DR. N. FOLSON spoke in favor of the practical bearing of the question, and mentioned a patient with fibroid tumor of the uterus under his charge who gets an evacuation only by means of large injections. She has learnt by experience that the bowels will not move until she has felt the water in her right side. If an enema, not too hot, be given standing and the desire to void it resisted, it certainly disappears from the rectum, as is shown by the way in which subsequent defecation takes place.

DR. F. H. DAVENPORT said that one does not really appreciate the capacity of the rectum until one introduces the whole hand, as was practiced by Simon, of Heidelberg, and finds how easily the hand can be moved about.

DR. CUTLER spoke of a patient at the Carney Hospital, with peritonitis, on whom colotomy was finally done, and whose pain was much relieved by the hot rectal douche.

DR. A. T. CABOT said that Monti, of Vienna, in 1876, used the rectal douche very freely in children for catarrh of the lower bowel. The water was not as hot as that employed by Dr. Chadwick, and it was used for its mechanical action in removing fecal matter and cleansing the parts rather than to allay hyperæmia.

In reply to a question from Dr. Buckingham the reader said that he was inclined to think it safer not to use the douche during the active stage of pelvic inflammation; in two cases in which he had employed it early he rather regretted having done so.

DR. BUCKINGHAM said that he had used the hot vaginal douche in one case of pretty acute pelvic cellulitis with comfort to the patient.

EXTENSIVE VENOUS THROMBOSIS.

DR. H. E. MARION reported the case and showed the specimens. A delicate woman of twenty-nine aborted at the end of the fifth month of pregnancy, December 4, 1879, having suffered for four weeks previously with occasional "cramps" in the stomach, and for two weeks with frequent desire to go to stool, straining, and small bloody discharges. She denied having taken steps to procure abortion. Soon after the abortion it was noticed that a cluster of veins just above the pubes were swollen and tender, that the legs were edematous, and the pressure along the course of the femoral veins caused pain. The patient said that she had suffered from a similar condition of things after each of three previous abortions, — at eight, seven and a half, and two months respectively. The urine was free from albumen.

December 8th. General anasarca; the distribution of the veins over the abdomen was very marked, even to the smaller divisions.

January 1st. On examination of the chest a soft murmur was heard over the apex of the heart and a friction sound at the base, possibly pleuritic. In the left scapular region there was dullness with bronchial breath and voice sounds, and below the scapula flatness and absence of respiration. Crepitant râles were heard at the right base in the back, and sonorous râles in front. The urine was still free from albumen.

January 10th. Thrombosis of the right external jugular, hypogastric, and branches of the mammary veins, with marked swelling of the neck and right arm, were noted. The arm was punctured, with marked relief to the pain.

January 20th. No great change in the last ten days, except gradually increasing weakness. Cellular inflammation of the right arm set in, and free openings were made as soon as fluctuation was detected. January 30th she died.

Autopsy sixteen hours after death. The abdominal cavity contained about a pint of clear serum, and the peritoneal surfaces were extensively adherent. The left lung was compressed by about five pints of clear serum, and pleuritic adhesions were found on the right side. The heart was normal, the spleen enlarged to more than twice the normal size, and the kidneys were hyperemic. Portions of the small intestine were covered with blebs filled with clear serum, and about four inches of the ileum were sphacelous; the mesentery belonging to this portion was thickened and thrombi filled the veins. The uterus was subinvolted and bound down by adhesions, and there was very extensive thrombosis of the ovarian, peri-uterine, iliac, and femoral veins and their branches, as well as of a portion of the ascending vena cava.

— Dr. Auerbach has treated pruritus very successfully with the balsam of Pern, by thoroughly rubbing it into the parts affected.

Recent Literature.

The Pathology of Mind. Being the third edition of the second part of the *Physiology and Pathology of Mind*, recast, enlarged, and rewritten. By HENRY MAUDSLEY, M. D. New York: D. Appleton & Co. 1880. Pp. 580, 12mo.

Two years ago we had occasion to notice the *Physiology of Mind*, it being the first part of the work referred to above (*JOURNAL*, March 28, 1878). The present volume completes the author's task, and supercedes all earlier editions by reason of having been so largely rewritten as to be in effect a new work. A new book from the pen of so well-known an author as Dr. Maudsley needs merely a brief notice in order to be generally read. In his preface he says, when commencing the study of mental diseases, twenty years ago, he found an almost complete divorce between psychology and the physiology and pathology of mind. It was his original endeavor, and is still his purpose, to unite these separate methods of treating the same subject, so as to benefit by their mutual relations.

For similar reasons, no doubt, he has included in the present volume chapters on Dreaming and on Somnambulism and its allied states, a scientific knowledge of which is essential to the proper study of insanity. They are also properly placed first, as these conditions lead up to the more permanent pathological mental states. The phenomena of insanity would excite less surprise and be better understood if always viewed in the light of more transient and familiar mental disturbances. We are all insane at times, during sleep, and the incoherence of dreaming, if prolonged into a state of muscular activity and carried out in action, would soon bring one to the asylum. The social importance of a knowledge of the frequency of varying states of consciousness with more or less automatic mental and muscular activity is great. Forms of religion, methods of healing, and questions of legal responsibility depend on it. The growth of intelligence in this direction would tend to destroy superstition by explaining many of our modern miracles, and would throw light on certain mysterious acts of violence and crime. The theory of separate cerebral centres of mental function is essential to the explanation of such conditions as hysterical catalepsy, mesmeric trance, mental epilepsy, hypnotism, somnambulism, and dreaming. The now generally admitted divisions of insanity into moral, intellectual, and instinctive mania, monomania, and other partial forms, with hallucinations of a single sense, also point to the same explanation; and the discovery of probable cerebral centres explains and supports these now well-recognized divisions of function.

Dr. Maudsley treats the causation of insanity from an evolutionary as well as a pathological stand-point. He regards mental degeneracy as a correlative of mental progress, and does not regret the humanization of the race at the cost of the individual. The advantage of studying insanity in its relation to social development is considerable, though we think the positivists sometimes overstrain their system in applying it to similarly complex subjects. Still there is no doubt great gain in the rearrangement of old facts on a new plan. By new associations, fresh and unsuspected relations are discovered. We hope the time is at hand when society will be compelled by the development of

a scientific conscience to act on the more recent result of sociology; when the social causes of insanity shall be as surely sought out and removed as bad drainage is soon likely to be. Vice, crime, pauperism, and insanity should be dealt with in the making, and our author's treatise goes far in pointing out the way. It should be thoroughly understood that when developed in the individual it is usually too late to eradicate these forms of mental degeneracy. But their propagation might be prevented, and their reproduction so interfered with as to reduce them to trifling proportions in two or three generations.

Dr. Maudsley devotes a chapter to the insanity of early life, which is instructive by showing different kinds of derangement corresponding to the stages of mental development. In infancy the reflex centres alone are affected, and convulsions instead of delirium occur from internal sensory irritation. A little later hallucinations with sensori-motor phenomena are observed. As soon as ideas have been organized in the child's mind insanity is possible, but as they are few and disconnected the disorder takes the form of very incoherent delirium, often with hallucinations and violent action. Choreic, cataleptic, epileptic, affective or moral, and instinctive insanity are the forms incident to the insanity of early life. Children have been the victims of misunderstanding for ages, and are still weighted with the odium of innate natural depravity, and this doctrine has derived support from the apparent precocity in vice of many undeveloped or mentally unsound specimens. There is no skill at concealment in children, and instinctive acts common to all animals often shock the observer, who attributes to the child a too mature and responsible mental development. The insane conduct of children and youth is specially horrible to contemplate. This dehumanization is the result of a pathological process, and exhibits a disorder of race acquisitions and not of the conscious traits of its individual being.

In describing the symptoms of insanity, our author treats it first generally as one disease, setting forth the symptoms as they occur at different times and stages of its course, and then delineates the different clinical groups of mental disorder which are met with in practice. We are unable, for want of space, to follow his accurate descriptions, careful analyses, and instructive theorizing. In regard to treatment, however, we desire to call the attention of those who have been in the habit of quoting Maudsley in support of their hostility to hospital treatment to his change of opinion on this subject. Many pages which our author formerly devoted to depreciation of hospital treatment have disappeared from the present edition. His former position was that none but dangerous lunatics should be sent to hospitals. He advised treatment in the families of physicians whenever possible, and indulged in some fine writing in favor of the personal liberty of the insane,—more creditable to his heart than his understanding, as it seemed to some conservative members of the specialty. He now admits that hospitals have greatly improved, as they evidently have in his estimation. He says, the difficulties, social, pecuniary, and legal, in the way of home treatment make few physicians, even if competent, willing to take the responsibility of it, though its possibility should be carefully considered in each case. He believes anti-social beings like the insane may be placed in confinement by society not only for the public safety, but for

medical treatment. He states very fairly the objections to private hospitals, and decides on the whole in favor of public asylums. The former, he thinks, will decrease and the latter increase with the growth of a more healthy public sentiment. He considers it hopeless to expect such a perfection of arrangements in either as will get rid of all complaints, since these grow out of the essential nature of insanity. The practice of placing patients in cottages under attendants, and at some distance from the hospital, he denounces in the strongest terms.

This change of tone and opinion seems to be the result of increasing experience, and is as creditable to Dr. Maudsley's sincerity as his former advocacy of personal liberty. I think but little exception can be taken to his present opinions, but they do not afford much satisfaction to lunacy reformers, who, like Dr. Hammond in this country, are using second-hand English ideas, never sound, and now becoming less prevalent where they originated.

Dr. Maudsley's style is so brilliant and forcible that his book will prove easy if not cheerful reading to all interested in its subject matter. If its stores of information could be wrought at once into shape and use, it would greatly benefit both individuals and society. We must confess to a feeling of discouragement, however, in view of the vast and overwhelming nature of inherited mental degeneracy, especially if a partially successful struggle against it is only to benefit the race. Is life worth living, in view of the numerous snares and pitfalls which preceding generations have prepared for us? Progress in humanization may prove to some an adequate motive for bearing up in the too often unequal struggle, but it does not support the instinct for life, as the hope of personal immortality would do. If none are in the long run fit to survive forever, what matters a few years more or less, or a little higher place in the social scale? If optimism and pessimism are matters of temperament only, why should we be cheered by hope or discouraged by adversity? "Let us eat and drink, for to-morrow we die!" and if sick and discouraged let us die to-day! T. W. F.

The Crayfish: An Introduction to the Study of Zoology. By T. H. HUXLEY, F. R. S. New York: D. Appleton & Co. 1880.

This volume is a very attractive addition to the International Scientific Series. Handsomely printed, and profusely illustrated with excellent wood-cuts, it at once prepossesses the reader; and the satisfaction is increased as he follows Professor Huxley's clear and most interesting descriptions of the marvels of the structure of the crayfish and of its relations to the lobsters and crabs. The work seems to us an example of the author's best style, and this is no small praise. Had Professor Huxley stopped with an account of the anatomy, physiology, and embryology of the crayfish, our notice might have ended with the last sentence, but unfortunately, as we think, he takes occasion to bring in a good deal of ultra-materialistic teaching. He presents this so skillfully and with such self-satisfied dogmatism that it is well fitted to mislead those who follow in the light of a great name without thinking for themselves. We cannot, of course, go into a discussion of biology, philosophy, and evolution, so we will take but a single instance. In speaking of the origin

of the crayfish Mr. Huxley says that it must be due either to creation, spontaneous development, or evolution. The first he dismisses at once as unscientific, the second he puts aside for want of evidence, and so we have only the third. Now we are perfectly ready to admit that it is most probable that crayfish, and indeed most animals, have been evolved from lower forms; but if we turn to the last lines of the book we find how unauthorized, not to say how silly a generalization Mr. Huxley indulges in. Returning to this same subject he concludes as follows: "By whatever verbal fog the question at issue may be hidden, this is the real nature of the dilemma presented to us, not only by the crayfish, but by every animal and every plant; from man to the humblest animalcule; from the spreading beech and towering pine to the *micrococci* which lie at the limit of microscopic visibility." That the dilemma is the same may be true without in any way implying that the answer is in all cases the same. Following out the author's idea, we of course must suppose an ancestor for the micrococcus, and another for him, and so on, as in the well-known case of the fleas:—

"All fleas have lesser fleas,
And these have fleas to bite them,
And these fleas lesser fleas,
And so *ad infinitum*."

So that unless we admit that some higher power created the first germ, which appears to be repugnant to Mr. Huxley, we must believe that it created itself, which is repugnant to common sense.

It is to be regretted that Mr. Huxley did not confine himself to the strictly anatomical side of the question, which he handles so admirably. T. D.

Experimental Researches on the Regional Temperature of the Head. By J. S. LOMBARD, M. D. London: H. K. Lewis, 136 Gower Street. 1879.

Dr. J. S. Lombard, formerly assistant professor of physiology in Harvard University, publishes in this book the results of extensive researches upon the temperature of different parts of the face and scalp, as obtained by surface thermometers or by a thermoelectric apparatus especially adapted for that purpose. His object was, first, to determine as far as possible the normal temperatures of those parts when the brain is comparatively quiescent, and then to study the changes produced in those temperatures by cerebral activity. He hoped that such observations might furnish reliable data for comparison with the temperatures of the head in morbid cerebral conditions, and that they might also throw some light upon the comparative importance of the parts played by different portions of the surface of the brain in intellectual work and in the various emotions. The formidableness of the task undertaken by the author may be surmised when we read the precautions which he finds it necessary to take in order to insure accuracy. "It is necessary," he says, "to know as much as possible concerning the various circumstances, both internal and external, affecting the subjects of examination: the general temperament, mental condition, occupation, — more especially what it has been just before the examination; the state of the circulation; the temperature of the atmosphere to which the individuals have been exposed before the experiment; whether they have been near a

fire, exposed to the rays of the sun or to draughts of air, etc., and if exposed to any of the above influences whether one part of the head was acted upon more than another; also the previous position of the head and body should be known, — whether one side of the head has been resting on a pillow, back of a chair, etc." In another place he adds that these numerous and unavoidable causes of interference may produce disturbances entirely beyond the control or even estimation of the observer. Indeed, when two parts of the head are exposed to the same external influences, one part may, for some unknown cause, be more affected than the other.

Then, again, the study of the effects of emotions on temperature would seem rather a difficult task to accomplish. One does not ordinarily keep his emotions on draught, as it were, to be dealt out in specified quantities on demand, nor can I conceive it an easy thing for a man to muster up pathetic or amorous emotions when his face is mapped out with chalk lines. On the other hand, a man in rage is hardly so docile as to submit to the gentle placings of a thermometer. Dr. Lombard does not consider that the temperature of any given point at the surface of the head is under the immediate control of the temperature of the portion of cerebral tissue lying directly beneath it, and that therefore a difference in the temperature of two points necessarily implies a similar difference in the corresponding portions of the brain; but he does think that the temperature of any given point on the scalp is "the resultant of its own temperature and of the different temperatures of all the parts lying beneath it." Imagine a cylinder cut out of the head; then the different layers of skin, muscle, bone, membranes, and brain will act as so many furnaces of different powers, and changes of heat production in one will affect the temperature of the others by conduction.

Dr. Lombard prepared cylinders of different substances, of poor heat conductivity such as paraffin, spermaceti, bees-wax, lard, and butter, and tested the rapidity with which a change of temperature at one end of the cylinder would affect a galvanometer pile applied to the other end. He found that a difference of temperature of 0.125° C. made itself manifest by conduction in three quarters of a minute, through 20 mm. of paraffin. He concludes that this experiment indicates that a slight change of the temperature of the brain may be quickly detected at the exterior of the head by a sufficiently delicate apparatus. With the possibilities of error so infinite and the probabilities of accuracy so minute, it would require a faith equal to a very large mustard seed to induce one to base very broad deductions upon data thus accumulated. However, Dr. Lombard has collected a large number of observations, — some sixty thousand, — and it may be that he has steered his way successfully through the forbidding obstacles which beset his path. The book is certainly a monument of great patience and painstaking. G.

— Hydrofluoric acid evaporated in the proportion of one gramme to each cubic metre of the sick-room, and thus inhaled by the patient, is said by Henri Bergeron to be a certain remedy for diphtheria. The evaporation should require three hours. "All who have been submitted to this treatment for forty-eight hours recovered."

Medical and Surgical Journal.

THURSDAY, APRIL 8. 1880.

A Journal of Medicine, Surgery, and Allied Sciences, published weekly by HOUGHTON, OSGOOD AND COMPANY, Boston. Price, 15 cents a number; \$5 00 a year, including postage.

All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.

Remittances by mail should be sent by money-order, draft, or registered letter to HOUGHTON, OSGOOD AND COMPANY, Boston, Mass.

THE ADMINISTRATION OF CHARITIES IN NEW YORK.

ON the 29th of March a meeting of representatives of the principal charitable institutions of New York was held at the rooms of the State Charities Aid Association, for the purpose of discussing the system of public aid for charities now in operation, and taking action in regard to the proposed reduction by the legislature of the *per capita* allowance granted by various special acts to these institutions. Fourteen societies were represented, and on taking the chair Mr. Theodore Bronson, of the State Board of Charities, by whom the conference was called, stated that within a few days several bills affecting their interests had been introduced in both houses of the legislature. The greatly increased cost of maintaining the poor of the city, he said, had long attracted attention, and the introduction of the bills mentioned, whose design was to cut down the *per capita* allowance, showed that unless some measures of economy were suggested by the societies themselves it would be forced upon them from without. The following facts showed that the time had come at least for some movement of inquiry as to the cause of this increased expenditure: "In 1865 the amount paid by the city to various asylums, reformatories, and other charitable institutions for the support and maintenance of inmates chargeable to the county was \$136,650, and the amount appropriated for the year 1880 is \$996,257. To arrive, however, at the whole amount to be paid during the present year to private institutions for the support of the poor, the excise fund must be added; and in 1879 this was \$342,513. In 1865 the amount appropriated for the Department of Public Charities and Correction was \$988,450; in 1880 it is \$1,318,383. That is, the city of New York paid \$1,125,000 for the support of its defective, dependent, and criminal classes in 1865, when the city had a population of 726,386 (or about \$1.50 per head); while in 1880, only fifteen years later, with an estimated population of 1,115,000, the city will spend about \$2,600,000, or more than \$2.50 per head."

After statements from representatives of various societies and hospitals (most of whom strenuously opposed any reduction in the *per capita* rates allowed them), Mr. Elbridge T. Gerry, of the Society for the Prevention of Cruelty to Children, remarked that within the last three months many cases of attempts to foist unnecessary burdens upon the city had been discovered, and read the first section of a bill introduced by Assemblyman Mitchell, which he said he

hoped soon to see a law, and which is as follows: "No child under the age of twenty-one years shall be committed to any prison, corporation, institution, or association whatever in the city of New York; nor shall any such child be received thereby or therein, except upon a warrant duly made by a justice of the supreme court, or by a court or magistrate having criminal jurisdiction." He thought the best remedy for many of the abuses now existing would be the establishment of a special central body or board to go behind the commitments of the police magistrates, and find out the circumstances of each case. This would prevent the bringing of children from other counties, or even other States, to be placed in the city institutions; and it has sometimes been found that a number of irresponsible persons hire a house, crowd it with children, and get the *per capita* allowance for the payment of salaries and the starvation of the children.

Mrs. Josephine Shaw Lowell, of the State Board of Charities, then made a forcible and practical address, in the course of which she said: "In regard to these charitable societies which you represent and which receive this *per capita* allowance, you may say that you have a moral responsibility, that the system which you have introduced is a good system to a certain point, and that it is certainly fair that if you give all your thought and time to this work you should have help from the public. But this system is open to the very grave abuse which Mr. Gerry has pointed out. Our board feel this, and on account of the relation which we bear to the charities of New York our attention has been called to these charities as a whole, and to the fact that this great increase in expenditure mentioned has occurred. And we say that as other and stranger and bogus societies are seeking to put themselves on a footing with those which you represent, you are the persons to whom we come, naturally, to get suggestions: in the first place, how the increase should be stopped in your own societies; and, again, how this increase in disreputable outside societies should be stopped. And I should like to say, what may seem very strange to some of you, who look upon this in a different light from what I do, that I do not consider these charities as a matter of pride to the city of New York. It seems to me that in this country, with the great facilities for earning a living, to have so many deserted children, so many paupers, so many criminals, so many persons sick in the hospitals, simply because they are drunken and bring on diseases by their vices; that to have their children left to the public to care for, to have such a mass of this deserted and criminal class, which it costs us two and a half millions of dollars, and over, to support,—I think that all this is a shame and a disgrace to the city of New York, instead of a matter of pride! It is not a matter of humanity. We are taking children that we ought not to take. If these went to private institutions only, if this fund were provided only by private benevolence, why, we might say the State is willing to give the \$2,000,000 to support the poor. But it is not so; every dollar of these two or three millions is taken from people who do not want to give

it. This is not charity. So long as the money comes from the taxpayers, they are not administering charities. Of course, your work is charity, but the money is not charity. And now it seems to me that, practically, the question is, How are we going to diminish this immense mass of dependent criminal population? Is not the trouble that it is too easy to gain admission to your institutions? We all know that, unfortunately, we cannot depend upon our magistrates, and there should be some means devised for going behind the commitments by them. There should be a central board, I think, which should undertake that piece of work, in some such manner as is done by the Hebrew Benevolent Society; for in this way you might cut off all the unworthy applicants. Then, another point is, whether the inmates — the children — are not kept too long in these institutions.

"My idea is that there might be some central board formed by representatives from the different institutions that are receiving the *per capita* allowance; that this board should attend to the investigation of cases of application, and have the power of granting permits; that each separate board of managers should not have this power; that the central board should be more or less a distributing centre; and that the most important part of the work, both of the central board and of the various institutions, should be the disposition of the children, because we all know that after all, no matter how good your care is in the institution, the main question is, What is to become of the inmates afterwards?"

After some further discussion a motion was passed to the effect that members of each of the societies represented should be selected to form a committee for consultation as to the best mode of remedying the evils which had been developed in the course of the conference, with Mr. Gerry as its chairman, and the meeting then adjourned.

MEDICAL NOTES.

— Von Schmidt, the notorious cancer curer, whose doings in London were exposed by the *Medical Press and Circular*, migrated to Paris, and is now in the hands of the police of that city for illegal practice.

— Dr. James Nevins Hyde has succeeded Dr. Byford in the senior editorship of the *Chicago Medical Journal and Examiner*.

— The ninth congress of the German Surgical Society will meet in Berlin in April.

— Rudolph Buchheim, professor of materia medica at Giessen, is dead.

— Dr. Notschawa, of Moscow, reports a case of double uterus with double conception. In consequence of hæmorrhage from both uteri, an embryo of one month was extracted from the left uterus, and from the right a fetus of three months.

— Dr. Alfred Carpenter has been urged to become a candidate for the representation of East Surrey in Parliament. Much to the regret of the English medical journals he has declined.

— The medical staff of Guy's Hospital have at last firmly asserted that they cannot perform their duties with a matron in authority over them. The governors, who heretofore have never interfered with the administration of the hospital, but have supported the lay treasurer and his scheme of nursing, have been forced to take up the question. What they propose to do remains to be seen, but the existing condition of things seems very curious.

— The coming meeting of the American Medical Association will be held in June, in the city of New York. Unusual efforts for an interesting meeting are being made by the committee of arrangements.

— Diphtheria is reported as prevailing to an alarming extent in Austria. It is said that not less than forty thousand persons have been its victims within a few months.

— A German railway physician asserts that railroad employees are more liable to affections of the spinal cord than any other class of men.

— Dr. Wilks, of Guy's Hospital, has been appointed physician to the Duke and Duchess of Connaught, in succession to Dr. Murchison. — Mr. Alfred Willett has been elected Surgeon to St. Bartholomew's Hospital, *vice* Callender, deceased.

— Alluding to the *Practitioner* of London, *Le Practicien* of Paris, the *American Practitioner*, of Louisville, the *Country Practitioner* of New Jersey, and, recently born, *The Practitioner* of Baltimore, the *Medical Press and Circular* says, "The new candidate for professional favor is bright, as most new things are, and we wish it the success its editors so confidently predict; but if gentlemen with literary aspirations cannot coin something fresh in the way of titles for their mushrooms, the *Index Medicus* will become muddled."

— At the thirty-third annual session of the Wisconsin State Medical Society, held at Milwaukee, June 4, 1879, the following resolution was offered by the secretary, Dr. J. T. Reeve: *Resolved*, that the State Medical Society of Wisconsin recommends the adoption of the metric system of weights and measures, and that in future that system be used in its printed transactions. Dr. Reeve stated that the metric system had been adopted by the American Association at Atlanta, that it was largely in use throughout the civilized world, and that he believed it right for the society to encourage its introduction in this way. Dr. Wilber seconded the motion, and after some discussion the resolution was adopted. On motion of Dr. Whiting the secretary was directed to insert in the next volume of the Transactions tables showing the relative values of the weights and measures in common use and those of the metric system. This has been done in the volume of Transactions just published.

— Professor Rouget has been appointed to the chair of general physiology in the Museum of Natural History, Paris, in the place of Claude Bernard. — Pettenkofer has received the Bavarian order of the Royal Crown.

— The scheme to bring sea-water to London has

been nipped in the bud by the Parliamentary Committee. The subsoil of the streets is already so crowded with pipes that it was deemed impracticable to introduce more.

—On the 7th of March Sir Thomas Watson, Bart., M. D., celebrated the eighty-eighth anniversary of his birth.

—San Francisco pharmacists are making the attempt to put an end, by legislative enactment, to the custom of paying physicians a percentage on prescriptions. According to *New Remedies*, physicians of San Francisco who thus share the profits of the apothecary write their prescriptions in cipher, and this journal calls the attention of the American Medical Association to this nefarious practice.

—The present inefficient and unscientific method of conducting executions was forcibly illustrated on Friday last. In one State a criminal of light weight was allowed to die slowly by suffocation, while at another execution, performed in a different State, the prisoner's head was completely severed from his body by the force of the fall. Sheriffs, generally unaccustomed to the task, are ignorant of the fact that this problem has been worked out scientifically, and that the elasticity or non-elasticity of the rope employed and the weight of the man must be carefully considered in estimating the number of feet "drop" required. As at present conducted, with its tedious preliminaries and clumsy make-shifts, the method may be considered little less than barbarous. If the poor wretches had happened to be dogs, we should doubtless hear of an earnest protest against the system.

PROVIDENCE.

—During the past two years the Providence Medical Association has been making efforts to establish a medical library on a plan similar to that of the Boston Medical Library. Mainly through the energy and perseverance of Dr. George D. Hersey, a large number of medical journals have been obtained, comprising files of nearly all the medical periodicals published in this country. In addition to this a reading-room has been maintained, open at all hours to members of the association, and furnished with the principal English and American journals. At the annual meeting of the association, held March 1, 1880, it was voted to transfer all the material thus accumulated to the Rhode Island Medical Society as a nucleus for the establishment of a state medical library. A subscription in aid of the same project has been set on foot among the profession of the State, and sufficient money has already been promised to warrant the belief that the enterprise will soon be placed upon a satisfactory basis. The need of such a library has long been felt.

—A case which recently occurred at the Rhode Island Hospital is of interest from the extent of injury produced by a comparatively slight cause. The patient, a man aged forty, in good general health, was raising an ordinary wardrobe to an upright position, when it slipped, and fell upon his left leg. He was taken to the hospital, where examination showed com-

minuted fracture of the tibia and fibula at the middle third, fracture of the external malleolus, and dislocation of the ankle. There was a pin-hole opening on the outer side of the ankle, and another just below the point of fracture of the tibia. The dislocation was reduced, and the leg put into a fracture-box. On the third day the whole leg became oedematous, and bullae appeared filled with bloody serum. On the fourth day amputation was performed just below the knee-joint. The flaps sloughed, and the patient sank rapidly, and died from exhaustion on the fourteenth day after the receipt of the injury. The tibia was found to be broken into ten pieces, the fibula into eight, the os calcis into nine, and the astragalus into seven, besides numerous splinters and fragments too small to be counted. The soft tissues of the leg were completely disorganized.

NEW YORK.

—The Society for the Prevention of Cruelty to Children has purchased the property at the corner of Fourth Avenue and Twenty-Third Street, opposite the College of Physicians and Surgeons, for \$43,000. The other corners are occupied by the National Academy of Design and the Young Men's Christian Association.

—Governor Cornell has appointed Dr. William H. Smith, of Angelica, Allegany County, health officer of the port of New York, in the place of Dr. Vanderpoel. Dr. Smith is much better known in the State as a politician than as a physician, although of good standing in the profession. He was a member of the legislature in 1856, and at present is one of the republican state committee. During the war he was surgeon for three years in the volunteer service, in which he attained the rank of brigade-surgeon; and later he was surgeon-general on Governor Dix's staff.

—The abortionist known as "Madame Berger" has been sentenced to the penitentiary for five years. In March, 1879, she was found guilty of malpractice, resulting in the death of Cora Sammis, of Long Island, and sentenced to the penitentiary for twelve years; after which her counsel carried her case to the supreme court on appeal, and obtained a reversal of the conviction and an order for a new trial. At this second trial, which has just taken place in the court of general sessions, the prisoner pleaded guilty, and the judge, in giving the above sentence, stated that he would take into consideration the facts that she had already been for a considerable time in prison, and that in thus pleading guilty she had saved the State the expenses of a week's trial. The man who brought the patient to Mrs. Berger to have the abortion performed is now serving a four years' sentence in state-prison, having pleaded guilty, on the 8th of July last, of being an accessory to the crime.

—The last lecture in the Saturday night free course at the Cooper Institute was given on the 27th of March, by Professor Charles F. Chandler, president of the board of health; his subject being, *The Earth's Atmosphere: Its Ingredients and its Influence on the Human Organism.*

— At the March meeting of the County Medical Society the paper of the evening was by Dr. A. D. Rockwell, on *The Sequelæ of Acute Diseases, and their Treatment: Diphtheria, Cerebro-Spinal Meningitis, Typho-Malarial Fever.*

— Sister M. Philippine Beaver, of the Roman Catholic Church, who came to New York from Baltimore in 1834, and for forty-six years has devoted herself to the work of ministering to the sick poor, principally in the hospitals, has just died at the advanced age of ninety-one years.

— The seventy-third annual commencement of the College of Physicians and Surgeons was held on the evening of March 12th, at Steinway Hall, and one hundred and seventeen more doctors of medicine were then graduated into an over-crowded profession. The address to the class was by Mr. Richard O'Gorman, and the valedictory by Frederick T. Hume. Dr. Robert F. Weir, president of the Alumni Association, in awarding the annual Alumni prize for the best medical essay (which was won this year by Dr. R. W. Amidon, of New York), said that none was awarded in 1879, because no essay of sufficiently distinguished merit had been presented. The present year, therefore, the prize was increased to \$500, and this increase would be made permanent through the liberality of Mr. Benjamin Cartwright, of Newark, N. J., who had given \$10,000 to the college, the interest on one half of which was to be devoted to the prize fund while the interest on the other half was to go towards founding a lectureship. Hence, in 1881, the Cartwright prize of \$500 would be awarded, and in 1882 the Alumni prize of the same amount.

The annual dinner of the Alumni Association came off at Delmonico's on the following evening, and about a hundred and fifty gentlemen were present. In the course of his remarks in response to the toast "Our Alma Mater," Prof. T. Gaillard Thomas reviewed the recent progress which the college had made in improving its methods of instruction. The regular winter session, which had formerly been but four months, had been extended to five months, and in the coming season would be still further extended to seven months. Graded courses had been introduced, a most efficient physiological laboratory established, and so many clinics had been added from time to time that now every department of didactic instruction was practically illustrated by this means within the walls of the college. The system of written examinations had also replaced the old superficial plan of oral ones by the professors. In conclusion, Dr. Thomas advocated, in order further to increase the efficiency of the institution, the starting of a subscription for a new building, where it might be entirely independent of any relations, possible or probable, with Columbia College, of which it is now the nominal medical department.

— At the last meeting of the New York Public Health Association, March 10th, Professor Chandler was reelected president, and Col. W. P. Prentiss vice-president. On this occasion a paper on the problem of tenement-house building was read by Mr. James Gallatin, who has devoted much time and attention to

the subject, and in his remarks at its conclusion Dr. Chandler said that in regard to tenement-house requirements the Board of Health had during the past year endeavored to enforce the new law in every case; but there were few precedents for guidance under the law, and each case had its peculiar phase. After the discussion that followed, Dr. Janeway reported upon the sanitary condition of the city. During 1878, he said, there were 28,342 deaths, which was an increase of 1300 over the number occurring in the preceding year; but this was less than the average. The increase was due to the greater mortality among children, which was principally owing to the epidemic of scarlet fever last winter; so that there were 378 more deaths from it in 1879 than in 1878. There was, however, less of diphtheria, pneumonia, bronchitis, and phthisis. There were 404 fewer deaths in the city during January, 1880, than in January, 1879, and 92 less in February than in the corresponding month of last year. In conclusion Dr. Janeway urged the necessity of systematic and thorough vaccination. Small-pox was at present prevailing to a considerable extent in Philadelphia and Washington, and it might appear in New York at any moment.

PHILADELPHIA.

— Dr. Marion Sims was present at Dr. Levis's clinic on March 24th, having come from New York by invitation of the lecturer for the especial object of witnessing the use of hydrobromic ether. Wyeth's bromide of ethyl was used, which Dr. Levis prefers to ether or chloroform, on account of its transitory influence, speedy effects, and more agreeable odor. Several minor operations were performed; the smallest amount given (for a child about nine years of age, in order to open an abscess) was less than a drachm, the time required to get her under the influence being forty-five seconds. Dr. Levis recently "ethylyzed" five cases with less than ten drachms of the new anæsthetic. The results have been very satisfactory thus far in this city, but no operation extending beyond three quarters of an hour has been performed with its aid.

— At a recent meeting of the County Medical Society, the president, Dr. Albert H. Smith, presented the subject of intra-uterine stem pessaries, which, in properly selected cases, had succeeded in his hands after every other means of treatment had failed. He preferred the modification of Dr. Chadwick, made of hard rubber, and a slender, flexible stem, carefully gauged to a quarter of an inch less than the length of the uterine canal, which in all cases is required to be previously measured by the sound. The paper was decidedly a valuable contribution to the subject of the treatment of obstinate flexions of the uterus. Great care was urged in the use of these instruments, but high praise was accorded them in appropriate cases. It was asserted that it did not necessarily prevent impregnation, but if not speedily removed would necessarily cause abortion. No deaths nor bad results directly attributed to the intra-uterine stem had occurred in Dr. Smith's hands, but in the general dis-

cussion many of the members of the society expressed a fear of its effects, and Dr. H. Lenox Hodge believed that equally good results could be obtained by the lever pessary and general and local treatment.

— Dr. S. Weir Mitchell, at the following meeting of the society, read some clinical observations upon locomotor ataxia, and presented crutches of novel form to aid the walking. He repeated mainly the views expressed in his clinical lecture published in the JOURNAL a year ago, and expressed a preference in treatment for large doses of potassium iodide, with efforts directed to the improvement of general nutrition.

— The abuse of medical charities, which for more than a year past has been made the subject of investigation by a special committee of the County Medical Society, was reported upon at the last meeting, and the resolutions adopted as recommended by the committee of conference already referred to editorially in these pages (see issue for March 4th). These resolutions were ordered to be transmitted to the next meeting of the Pennsylvania State Medical Society, to be held in Altoona, May 19, 1880, with the approval of the society, and the request that copies be sent to other state associations.

CHICAGO.

— The past six or eight weeks have witnessed an epidemic of measles in Chicago such as we have not had for a dozen years. It seems as though hardly a child was to be spared the annoyance and danger of this disease. The cases are generally mild. Very few deaths, comparatively, occur.

— Dr. Thomas Bevan, one of the best known and most highly respected members of the profession, died suddenly on the 15th ult. He had practiced in Chicago a quarter of a century; had been for many years one of the physicians to the County Hospital; had occupied for several years the chair of hygiene in the Chicago Medical College; was a member of the Chicago Medical Society, of the Medical Press Association, and of the Medico-Historical Society. Perhaps no medical man has been held in higher estimation by all classes and people who knew him than Dr. Bevan. He had the early advantage of a classical education, studied several years abroad, and was in every way fitted to be an ornament and an honor to the profession, as he was.

— The annual Commencement exercises of the Chicago Medical College took place on the 30th ult., with a graduating class of thirty-seven. The Alumni Association held their reunion and banquet in the evening at the Tremont House. This college has instituted a course of instruction for practitioners, which began April 1st, to continue five weeks. Thirty physicians so far have paid the fee of thirty dollars for the course.

— Dr. Joseph P. Ross, for many years one of the physicians to the Cook County Hospital, has resigned this position. Dr. Norman Bridge has been appointed his successor.

— Chicago is having its share in the discussion of the abuse of medical charities. The oldest medical

society, at a recent meeting, had a report on the subject from a committee appointed for the purpose. The report will probably fail of any particular good, for the reason that it was chiefly devoted to the arraignment of the *rings* of old doctors, who, it was alleged, were managing the dispensaries in their own way, and denying the young men any voice in the same. The document apparently bears the finger marks of young men who feel hurt at something. Nevertheless, the little that is said against the real abuse of the charities meets the hearty approval of the profession. The secretary of the largest free dispensary (the Central) is busy trying practically to devise means for preventing people who own property and are receivers of rents from receiving free treatment at the dispensary.

Disclaim.

A NEW VERMICULAR SOUND AND CATHETER.¹

BY J. H. WARREN, M. D.

I TAKE pleasure in presenting to you a new urethral sound and dilator, which combines in its action the screw and the wedge. By its peculiar spiral motion it avoids to a very great extent the friction met with in using the sound and dilator of Otis and others in common use, since but a small portion of the urethral canal is in contact with the instrument at any one time. It will be seen that it partakes of the spiral twist in common with my new aspirator and syringe for injecting hernia. This new idea in surgical instruments was suggested to me while treating an old and difficult stricture last spring. I found that I could introduce the ordinary dilator with much greater ease and with far less pain by giving it a twisting motion. I think you will find, if any of you have under treatment long and tortuous strictures, that this dilator will glide through with great ease, and will fully accomplish its purpose with much less pain than the sounds in general use, and here rapid dilation is well borne, and it can be accomplished in half the usual time, with but little pain to the patient.

I hope it will be my pleasure to exhibit at each meeting for several months to come new instruments for the treatment of the male and female urinary organs, and for other surgical operations. Should they worm through contracted and strictured parts in your hands as perfectly as they have in mine, I shall think I have aided to revolve the wheels of advancing surgical science.

These instruments can be obtained of the varied sizes which are in general use, American or French scale.

CASE I. On January 12th Mr. — applied to me with a very severe stricture of several years' standing. He was unable to pass a stream of water larger than

¹ Read before the Suffolk District Medical Society.

a small knitting-needle. It was impossible to introduce the smallest sound through the stricture without the greatest pain, and it had been said by several physicians who had attempted it that, owing to the extent of the contracted and strictured canal, it would be impossible to pass again a catheter or sound. I passed this instrument which I now show you with such little pain to the patient that he asked if I had really penetrated through the stricture. Upon learning that I had, he said he never had one introduced so easily and successfully before.

The vermicular catheter is in shape like the catheter in common use except at its point. This point is about one and three tenths centimetres long, of the same peculiar wedge shape, and revolves in precisely the same manner as the vermicular sound and dilator. On account of its shape and power of revolving it is passed through and made to dilate the urethra with very little friction, and of course with far less difficulty, and with little or no pain when compared with the usual catheters.

CASE II. Mr. B., age sixty-six, has had an enlarged prostate, and for many years has passed his water with great difficulty, and in a very small and irregular stream. The parts were so compressed by this enlarged gland that it was impossible to introduce a common catheter or a soft rubber bougie, No. 9 French or No. 6 American scale, yet this vermicular catheter passed with perfect ease and without pain into the bladder. It has to be used only once to show its superiority over every other catheter in the ease and freedom from pain with which it penetrates the strictured parts during catheterization. These catheters are made for both male and female.

They are introduced in the ordinary way, the staff being held firmly in the hand; but the withdrawal should be gradual, little force being used in order that the mucous membrane may not close around the vermicular point.

THE ADMISSION OF WOMEN TO THE MASSACHUSETTS MEDICAL SOCIETY.

MR. EDITOR, — Having seen an opinion of mine referred to in your columns, perhaps it will not appear presumptuous in me to state some of the facts as they occur to me on that exciting subject, the admission of women to the Massachusetts Medical Society. Let me say just here that I am not and never have been opposed to the admission of women *per se*. Were I now to form a new Massachusetts Medical Society, I would by all means make a provision for the admission of women. But I cannot see how any unprejudiced person who studies the history and charter of the society can come to any other conclusion than that the society was not made for women. For almost one hundred years (the charter was enacted November 1, 1781) the society has been in existence, performing various important duties under the direction of the laws of the commonwealth, increasing its membership from twenty-seven to thirteen hundred or more, and no woman has ever been admitted as a resident or honorary member. And during this whole period there has been a large penalty for unreasonably refusing to examine any candidate offering himself for examination respecting his skill in the practice of physic and surgery, or for admission to the society. And no person has ever discovered that a great wrong has been

committed against the female practitioner. No gallant lawyer, among the many hundreds practicing in the commonwealth, who are ever ready to see that justice is done to the humblest inhabitant, has ever discovered that female physicians had rights that the censors of the Massachusetts Medical Society were bound to respect. The history of the society is an honorable one, and in all its acts where there has been a controversy it has been sustained by the courts. It has firmly adhered to its chartered rights, and has never invaded others.

So much for the history of the society. Now let us look at the charter. The legislature, on the first day of November, 1781, enacted "that Nathaniel Walker Appleton and twenty-six others be and they are hereby formed into, constituted, and made a body politic and corporate by the name of the Massachusetts Medical Society;" and they and their successors are to enjoy their rights without limit of time or reservation of power to alter or abridge them. Their duties and privileges are specifically defined, and penalties affixed for the non-performance of some of them. Twenty-seven physicians of Boston and the vicinity, gentlemen remarkably scrupulous in regard to all matters of propriety and ethics, composed this corporate body. Can any one believe that these gentlemen would have refused the admission of women if they supposed that the law intended to include them as the probable Fellows of the society? The intention of the act of incorporation is patent from a supplementary act passed March 8, 1803, twenty-two years after the first act, which provides "that the Fellows of the said corporation shall not be liable to be enrolled or mustered in the militia of the commonwealth" — a provision certainly not supposed to be applicable to females, but which was very acceptable, no doubt, to many of us during the last war. There is no subsequent act that provides for the admission of females. The law of 1859 only changes the word "candidates" to "persons," and does not pretend to alter the intent of the charter; and besides that law has never been accepted by the society, or its provisions acted upon as of any binding force. It therefore seems clear to me that the Massachusetts Medical Society was not made for females any more than the offices of judges of the courts or justices of the peace. What prevents our good governor to-day from appointing women to either of those offices? I know of no provision of the constitution or the laws that forbids it. The intent of the law alone forbids it. As was said to Governor Andrew, those offices were not made for women.

I only wish to say further a few words in relation to the opinion of Messrs. Hoar and Putnam. With all deference to the opinion of those gentlemen, I must be allowed to remark that I have found that the opinion of a lawyer, however eminent, is not *law*, and I respectfully submit that the censors have no questions to decide in regard to candidates except as to their knowledge of physic and surgery and their moral character. They must be governed by the usages of the society and the *intent* of the chartered rights in regard to whom they are obliged to examine; and that if the censors should examine any woman respecting her skill in the practice of her profession; and find her fitted for the practice of it, and approbate her with letters testimonial of such examination and approval, she would not *necessarily* be entitled to membership of the society.

What, then, shall be done in regard to the admission of women to the Massachusetts Medical Society? I would not hastily remove the ancient landmarks, or reverse the practice of the society for a hundred years, when at least a large and respectable minority would be grieved thereby. I would not admit women by a bare majority of any meeting of the councilors or of the society or both. It is not action worthy of the object. It is a sort of stealing into the fold which no

lady can desire. As the society is a corporate body, acting under a charter that did not contemplate the admission of women, let the legislature amend the charter so as to admit females, and let the society accept of that amendment, and then we shall avoid all future contention about the matter.

It is always best to accomplish a good work if possible in a natural way.

A. MILLET.

REPORTED MORTALITY FOR THE WEEK ENDING MARCH 27, 1880.

Cities.	Population estimated for July, 1879.	Reported Deaths in each.	Deaths under Five Years.	Percentage of total Deaths from

Two thousand five hundred and nine deaths were reported; 984 under five years of age: principal "zymotic" diseases (small-pox, measles, diphtheria and croup, diarrheal diseases, whooping-cough, erysipelas, and fevers) 398, consumption 408, lung diseases 403, diphtheria and croup 144, scarlet fever 51, measles 51, whooping-cough 39, diarrheal diseases 35, typhoid fever 32, erysipelas 20, malarial fevers 17, cerebro-spinal meningitis 11, typhus fever two, small-pox one. From *measles*, New York 13, Brooklyn and Chicago eight, Philadelphia seven, Pittsburgh five, St. Louis three, Lowell two, Cincinnati, Buffalo, New Haven, Worcester, and Fitchburg one. From *whooping-cough*, New York and Pittsburgh six, St. Louis and Cincinnati four, Philadelphia and Boston three, Chicago, District of Columbia, and Charleston two, Brooklyn, Baltimore, Cleveland, New Haven, Worcester, Palmer, and Bridgewater one. From *erysipelas*, Philadelphia six, Brooklyn four, New York three, Chicago, Boston, Cincinnati, Cleveland, Pittsburgh, Lowell, and Fall River one. From *malarial fevers*, New York 12, St. Louis two, Brooklyn, Baltimore, and Cleveland one. From *cerebro-spinal meningitis*, New York three, Philadelphia, Chicago, and Worcester two, Pittsburgh and Providence one. From *typhus fever*, Chicago and Cleveland one. From *small-pox*, Philadelphia

one. One hundred and sixty-six cases of measles, 34 of diphtheria, 28 of scarlet fever, and one of typhoid fever were reported in Brooklyn; diphtheria 29, scarlet fever nine, in Boston; diphtheria 26, scarlet fever 14, in Milwaukee; scarlet fever 30, diphtheria 13, erysipelas two, cerebro-spinal meningitis one, in Providence; diphtheria three, scarlet fever two, in Cambridge; scarlet fever 13, diphtheria six, in New Bedford.

The total number of deaths reported is about the same as for the previous week, of deaths under five considerably greater. Lung diseases and measles were more fatal. In 37 cities and towns of Massachusetts, with an estimated population of 1,020,960 (population of the State about 1,690,000), the total death-rate was 21.96 against 21.47 and 19.46 of the previous two weeks, lung diseases and scarlet fever having been more fatal than during the previous week, typhoid fever less so.

For the week ending March 6th, in 143 German cities, with an estimated population of 7,673,279, the death-rate was 28.2 against 27.1 and 27.4 of the previous two weeks. Four thousand one hundred and sixty-three deaths were reported; 2051 under five; pulmonary consumption 601, acute diseases of the respiratory organs 550, diphtheria and croup 130, typhoid fever 68, scarlet fever 63, whooping-cough 54, measles and *roteln* 49, pu-

erperal fever 21, small-pox (Dusseldorf and Dresden) two, typhus fever two. The death-rates ranged from 14.1 in Duisburg to 42.7 in Halle; Königsberg 30.5; Dantzie 27.1; Breslau 32.2; Munich 38.2; Dresden 22.7; Bremen 23.3; Leipzig 31.0; Hamburg 28.2; Hanover 27.2; Breun 26.7; Cologne 25.0; Frankfurt 30.1. For the same week, Vienna 33.3; Paris 29.8, — small-pox, diphtheria, and typhoid fever continuing very prevalent.

For the week ending March 13th, in the 20 English cities, with an estimated population of 7,999,468, the death-rate was 21.4 against 22.1 and 23.1 of the previous two weeks. Three thou-

sand and seventy deaths were reported: diseases of the respiratory organs, 315, whooping-cough 173, scarlet fever 90, measles 80, fever 40, diarrhoea 35, diphtheria 17, small-pox (London) thirteen. The death-rates ranged from 15.6 in Portsmouth to 37.3 in Plymouth; London 30.5; Bristol 21.0; Birmingham 21.7; Liverpool 22.5; Manchester 25.9; Leeds 21.6. In Dublin 36, Glasgow 26, Edinburgh 18. In the 20 chief Swiss towns, lung diseases and diphtheria continued very prevalent, typhoid fever somewhat so; small-pox caused two deaths in Zurich.

The meteorological record for the week in Boston was as follows:—

Date.	Barom-eter.	Thermom-eter.				Relative Humidity.				Direction of Wind.			Velocity of Wind.			State of Weather. ¹			Rainfall.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U. S. ARMY, FROM MARCH 27, 1880, TO APRIL 2, 1880.

BREWER, J. W., captain and assistant surgeon. The sick leave granted him from A. G. O., September 22, 1879, extended three months on surgeon's certificate of disability. S. O. 67, A. G. O., March 26, 1880.

DEWITT, C., captain and assistant surgeon. To accompany Company B. Ninth Infantry, from Fort Sidney, Nebraska, to Fort Niobrara, and report to the commanding officer thereof for duty. S. O. 26, Department of the Platte, March 26, 1880.

MOSELEY, E. B., captain and assistant surgeon. Having relinquished remainder of leave of absence, relieved from duty with the Ute expedition, and assigned to duty at Fort Sidney, Nebraska. S. O. 26, C. S., Department of the Platte.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE HOSPITAL SERVICE, JANUARY 1 TO MARCH 31, 1880.

BAILHACHE, P. H., surgeon. Detailed as president board of examiners to convene in Washington, January 26, 1880. January 14, 1880.

MILLER, T. W., surgeon. Detailed as member board of examiners to convene in Washington, January 26, 1880. January 14, 1880. To proceed to Chattanooga, Tenn., as inspector. January 14, 1880.

WYMAN, WALTER, surgeon. Granted leave of absence for twenty-one days from February 7, 1880. February 6, 1880.

MURRAY, R. D., surgeon. Granted leave of absence for twenty days from April 10, 1880. March 16, 1880.

FESSENDEN, C. S. D., surgeon. Detailed as recorder board of examiners to convene in Washington, January 26, 1880. January 14, 1880.

FISHER, J. C., assistant surgeon. To report to board of examiners for examination for promotion. January 28, 1880.

WHITE, ROBERT, JR., assistant surgeon. Granted leave of absence for thirty days on account of sickness, from February 23, 1880. February 21, 1880.

O'CONNOR, F. J., assistant surgeon. To proceed to Evansville, Ind., and assume charge of the service at that port. March 17, 1880.

WHITE, ROBERT, JR., assistant surgeon, died at New York, N. Y., February 24, 1880.

SUFFOLK DISTRICT MEDICAL SOCIETY.—A meeting will be held at the hall, No. 19 Boylston Place, on Saturday evening, April 10th, at seven and a half o'clock. The following papers will be read: Dr. C. E. Wing, Modern Abuse of Gynecology. Dr. L. Foster, The False and the True in Therapeutics. Disputant, Dr. H. D. Hicks. Professor Butterfield, Visible Speech. All members of the Massachusetts Medical Society are cordially invited to be present and to take part in the discussion.

T. M. RORCH, M. D., Secretary.

ERRATA.—In the article entitled Death from Narcotism, on page 334 of the last JOURNAL, by Dr. J. W. Parsons (not T. W.), the amount of chloral hydrate in the prescription should have been printed *three ounces*, not three drachms.

BOOKS AND PAMPHLETS RECEIVED.—The Student's Manual of Venereal Diseases. Being the University Lectures delivered at Charity Hospital, Blackwell's Island, 1879-80. By F. R. Sturgis, M. D. New York: G. P. Putnam's Sons, 1880. (A. Williams & Co.)

On Rectal Alimentation and the Induction of Abortion for the Relief of the Obstinate Vomiting of Pregnancy. By William Warren Potter, M. D. Batavia, N. Y. (Reprint.) New York: William Wood & Co. 1880.

Health and Health Resorts. By John Wilson, M. D., late Medical Inspector of Camps and Hospitals in the United States Army. Philadelphia: Porter and Coates. 1880. (For sale by Estes and Lauriat.)

The Essentials of Anatomy. Designed as a Text-Book for Students, etc. By Professor William Darling, M. D., F. R. C. S., and Ambrose L. Ranney, A. M., M. D. New York: G. P. Putnam's Sons. 1880. (A. Williams & Co.)

The Seventh Annual Report of the Board of Health of the City of New Haven. 1879.

104. Albuminuria as a Symptom of the Epileptic Paroxysm. W. H. DeWitt, American Journal of the Medical Sciences, April, 1875, page 460.

By albuminuria we mean the appearance in the urine of that variety of albumen detected by heat and nitric acid. Other albuminoid bodies have also been recognized, but as they are disclosed by different processes they need not occupy us here.

Since the discovery of this substance, the views in regard to its importance and significance have undergone continual modifications, and do not yet rest upon a perfectly stable basis. Albumen long ago lost its position as a factor in any one disease, but the demonstration of this error was accompanied by a large addition of truth, and stimulated new investigations, which have been carried on at the bedside and in the laboratory, until the literature of the subject has become so extended as to make a *résumé* of it indispensable to the student.

The attempt has been made to trace to their sources and verify the common statements and beliefs. Some of these have no foundation whatever, but are mere assertions copied by one writer from another. Many more are based upon cases which do not contain the elements for any legitimate conclusion, and others are so contradictory as to make any decision upon their merits impossible. But behind all these is a large amount of material, the fruit of the best scientific research, which throws a flood of light upon this most intricate problem.

DOES NORMAL URINE CONTAIN ALBUMEN?—This is naturally the first question which presents itself. The affirmative statements formerly made have been contradicted so decidedly by the best observers as to oblige us to answer in the negative (1. v. 9th) (11. v. 44, p. 18th). We must admit, however, that it may make its appearance under such conditions as to show only a very slight deviation from the natural state. Thus the urine of one hundred and nineteen healthy soldiers, tested immediately after rising, showed albumen in 4.2 per cent. (28). Still more recently, the urine of a large number of applicants for life insurance was tested with special care by Dr. Munn, of New York (46), and albumen was detected in 11 per cent., though in two doubtful cases only was there any reason to suspect disease. Notwithstanding these statements and others of the same character, we may still maintain that *normal urine does not contain albumen*. The highest percentage of its presence is so low as to demonstrate this law.

THE CONDITIONS UNDER WHICH IT OCCURS.

It is very difficult to give a complete statement of these, as more frequent and thorough examinations of urine are constantly extending the list, but the following table includes those most commonly met with, and some which are quite rare. These are arranged in alphabetical order, for convenience of reference, and because it would obviously be premature to make an attempt at classification at the outset of an inquiry like this, the object of which is to ascertain the significance of a symptom. It will be time after certain laws are established to apply the latter to cases or groups of the same.

The changes produced by the above agencies, will be discussed under the following general heads:—

(a.) Albuminous matter in the pelves of the kidneys, in the ureters, the bladder, or the vagina.

(b.) Disturbances of the circulation.

(c.) Disturbances of the nervous system.

(d.) Diseases of the kidneys.

(e.) Changes in the blood.

(f.) Indigestion.

We shall attempt to show:—

(a.) That albuminuria frequently depends upon disturbances of the circulation of the kidneys, but, contrary to the common belief, that this disturbance is quite as likely to be *owing to the diminution of pressure* as to its increase or congestion, as it is commonly called, and that *dilatation of the vessels, with a diminished rapidity of the current, may be very important factors.*

(b.) That the action of the nervous system depends upon its influence over the circulation.

(c.) That in disease of the kidneys themselves the epithelium, if it have any connection with the appearance of albumen, acts rather mechanically than otherwise.

(d.) That the changes in the interstitial tissue cause disturbances of the circulation, and that serous infiltration or inflammation of this tissue may furnish albuminous products which escape with the urine.

(e.) That the blood-vessels may be so changed as to allow albumen to pass more readily.

(f.) That the blood itself may undergo certain modifications, but that a variation in the proportions of neither water nor albumen can be demonstrated.

(g.) That the products of digestion probably fail to undergo the usual changes, and consequently appear in the urine.

SOURCES EXTERNAL TO THE KIDNEYS.

In speaking of albuminuria dependent upon actual disease, we must remember that its cause may be found in other portions of the genito-urinary apparatus besides the substance of the kidneys, such as the pelvis of the latter, the ureters, the bladder, the urethra, or the vagina. In such cases it is attributable to the presence of the spermatic fluid, pus, or blood. It is sufficient now to speak of these forms very briefly. The abnormal ingredient being detected, its significance must be sought in connection with the fluid of which it is a part.

SPERMATIC FLUID.—It is stated that the presence of this may cause albuminuria (20, p. 121), and such would be inferred from the character of the secretion itself. The urine, however, must be passed under exceptional circumstances, and the amount of spermatic fluid must be considerable, as albuminuria can rarely be traced to this cause (68, p. 108). It is sufficient to call attention to the fact, to guard against error in diagnosis, as the presence of numerous spermatozoa, in the absence of all other causes, would make the case perfectly clear.

PUS.—This contains much albumen, but the quantity of the latter found in the urine is generally small (1), though derived from the serous portion rather than the corpuscles. Senator (38, p. 488) noticed in five cases of catarrh of the bladder only a moderate amount of albumen, much less than in true cases of renal albuminuria.

BLOOD.—The amount of albumen is greater in proportion to the quantity of blood than with the same amount of pus. It may be derived from the serum of the blood (42, p. 718) and from the red corpuscles, as in hemoglobinuria, which will be merely referred to here, as the full consideration of it belongs properly elsewhere.

SIGNIFICANCE OF RENAL ALBUMINURIA.

After excluding the above varieties, is it possible, on examining the various conditions under which albumen is found, to arrive at any satisfactory conclusion in regard to the cause or causes which influence its appearance? We have seen that it may occur in mere changes of position, almost inseparable from existence; in the simplest and most transient variations from the normal condition; in a great variety of diseases, affecting all parts of the body, with or without formative changes in the kidneys themselves, and with lesions of the latter alone. Often there are acting at once many supposed causes, each of which has been seen separately in connection with albuminuria.

Can we, without farther investigation, fix upon anything common to all of these cases, or can we divide them into groups, each of which has a separate explanation? The closest scrutiny of each case, the most comprehensive view of the mass of cases, fail to show anything but the extreme complexity of the problem. We cannot move beyond the stage of mere inquiry, suspicion, or suggestion. Can chemistry aid us by showing a difference in the albumen found under various circumstances, of such a character that, being detected, we can attach it to a peculiar condition or form of disease? It is difficult to make a perfectly satisfactory distinction between the different albuminoid substances, as their chemical elements are too little known (28, p. 180); but, if several bodies of this character appear in the urine under various circum-

stances, in varying quantity, and in variable proportions to each other, they are detected in different ways, by different reagents, so that the usual method of testing by heat and nitric acid would not disclose their presence, and they cannot, therefore, be the cause of error. They are, however, important to remember in case future observations should show that they have any special value in diagnosis.

It is sufficient now to know that chemical tests prove very clearly that *the form of albumen usually found resembles that of the serum of the blood* (11, v. 44, p. 520). In some exceptional cases, albumen like that of the egg may pass, after its introduction into the body, and we may therefore admit that such is possible under some special conditions to be mentioned hereafter. As, with this single exception, the albumen resembles that of the serum of the blood, we naturally suspect that it in some way escapes from the latter. To settle this point, let us examine the conditions under which it occurs, and see how far they are of such a character as to make the escape by filtration possible or probable. In such an investigation those cases should be considered first which are so simple in their character as to appear to depend upon mere disturbance of the circulation, without structural or other changes. Our attention is first attracted to the temporary albuminuria of persons otherwise healthy, apparently attributable to a change of position or to exertion; but here, though the change is simple, its cause is difficult to appreciate, as we have no other factor to work with. If we knew the condition of or the degree of tension in the arterial and venous systems, we might come to some definite conclusion in regard to the cause; but in the absence of this knowledge, *we must select some case or class of cases in which there is a single easily recognizable deviation from the normal state.*

VALVULAR DISEASE OF THE HEART.

Such is found in those instances of valvular disease of the heart where there is albuminuria without structural change of the kidneys. Here the albumen does not make its appearance until cardiac failure is shown through a feeble pulse and cyanosis, while at the same time the quantity of urine may diminish and its specific gravity increase. If this disability of the heart becomes permanent the albuminuria is also permanent (1, v. 9^e, p. 38), but if, by rest or the use of the proper remedies, the power of the organ is increased, the pulse rises, there is a greater flow of urine, and the albumen disappears. *The fact that no other morbid element is found in the urine, that this is no longer found when the derangement of the circulation is relieved either by rest or some other efficient remedy, makes it probable that there is no histological change in the kidney itself,* while the evidences of general venous congestion are marked. The kidneys participate so necessarily in this congestion as to lead to the almost universal belief (1, v. 9^e, 14) that it is instrumental in giving rise to the albuminuria by increasing the pressure. The supporters of such an interpretation apparently strengthen their position by citing as evidence cases of albuminuria occurring with thrombosis of the renal veins or of the lower vena cava (35, p. 55), with embolism arising from the transportation of coagula (7), or of fragments of pigment which originate in the spleen in intermittent fever (11, v. 45, p. 120). The same consequences have followed the compression of the vena cava by tumors (11, v. 45, p. 122), or by a distorted

spine (1, v. 9^e, p. 41), which in certain positions caused displacement of the heart, and thus interfered with the circulation, while the albumen disappeared when the position was changed.

Experiments seemed to confirm this view still farther. Thus albuminuria has occurred when the renal veins have been tied (7) (90) (21, p. 276), when the vena cava has been plugged, when the movements of the heart were interfered with by a small ball of india rubber passed down the jugular vein into the right ventricle, or when quantities of fluid were injected quickly into the jugular vein (7). Litten (103, p. 162) in his experiments found that after the renal vein had been tied two hours albumen collected in the capsules around the glomeruli and in the commencing portion of the convoluted tubes, sometimes mingled with a little blood. As the albumen increased with the congestion, (1, v. 9^e), and disappeared when the latter was relieved, even after it had persisted for a long time (35, p. 226), it seemed necessary to admit the effect of venous stasis and most observers accepted this conclusion without farther inquiry. Overlooking the peculiarities of the circulation of the kidneys, *they left congestion to do its work as in other parts of the body.* But we cannot overlook these peculiarities. We must remember that there are interposed between the intertubular capillaries and the arteries special structures, the Malpighian bodies. The latter appear to be under more favorable conditions in venous congestion than the other capillaries, and not to be subjected to the same pressure (38, p. 496), which must fall particularly upon the intertubular veins. At the same time there is less tension of the glomeruli, owing to the diminution of the arterial pressure, unless we assume that all parts of the closed circle through which the blood passes must necessarily feel equally the effects of an obstruction in any part. While we may admit that when the heart is acting with its usual force closure of the renal veins would necessarily increase the tension of the glomeruli, it must be borne in mind that the conditions are very different in valvular lesions, where the obstruction is so situated as to diminish arterial pressure, unless fully compensated for by hypertrophy; and it is precisely when this compensation falls below a certain point that the albuminuria begins. Though we have no data based directly upon observations of pressure in different parts of the circulation in connection with diseases of the heart, the natural difference between the tension in the arterial and venous systems appears to have an important bearing. Carpenter quotes Volkmann (63, p. 337) as giving a proportion of three to one in favor of the arterial over the venous pressure. *This great excess under normal conditions makes it impossible for us to infer that the tension of the venous system in obstructive valvular disease is such as to cause greater pressure in the glomeruli than in health.* Moreover, we are told by Rosenstern (1, v. 6, p. 34) that in the disease in question the pressure in the veins does not increase as much as that in the arteries diminishes. It must be doubted also whether, under any circumstances, the lateral pressure in the veins is as great as in the glomeruli (35, p. 229). Bartels himself, though an advocate of congestion, admits (1, v. 9^e, p. 39) that the glomeruli are not particularly distended in the cyanotic kidney, and the quantity of urine is diminished, not increased, as it is in distention (54, p. 97). With this evidence that all parts of the circulatory system of the kidneys are not

equally and similarly affected in obstructive disease of the heart, *we must attempt to decide from which part the albumen escapes*. The question is not closed, though some of the best observers, influenced by the above considerations, have declared that albumen must and does pass through the walls of the intertubular capillaries. But the distribution of these does not favor the escape of their contents into the tubuli, as they are not in immediate contact with the latter, but are surrounded by lymphatic spaces, which may receive the transudation from the capillaries and carry it away through the lymphatic vessels (35, p. 55). Still further, if the albumen escapes into the tubes, it must pass through the *membrana propria* and the epithelium, which experiments show is very difficult (35, p. 56). In connection with the albumen we frequently find blood globules, which, if derived from the intertubular capillaries, must pass through the thick basement membrane. If the latter occurred there should be evidences of intertubular hæmorrhage, which is, however, exceedingly rare, if seen, whereas it ought to be common if blood escapes into the tubuli from these vessels (33, p. 240).

These anatomical objections seem to be met, however, by the instances mentioned in which albuminuria has followed immediately the obstruction of the venous system of the kidneys, and still more completely by the discovery of albumen in the tubuli (103, p. 166). But we must bear in mind that all of these are not necessarily accompanied by increased pressure: that in some of them the pressure may be greater than in disease of the heart, and that in others various changes take place beyond mere congestion, as in hæmorrhagic infarct, in the inflammatory processes following thrombosis, embolism, and ligation of the veins. It is only necessary that the blood-vessels should be tied a very short time for the production of these serious secondary effects upon the kidneys (1, v. 9, p. 55) (11, v. 45, p. 24), though we may have only serous transudation (35, p. 262). Even the discovery of albumen in the tubuli (95), (103) is no proof that it transuded into them, as whenever found there it is also found in the capsules, and it must inevitably escape from the body through the tubuli. We are not aware that it has appeared in the tubuli and not in the capsules; but this might well occur, as, escaping from the glomeruli, it might be retained in the canals after the transudation had ceased at the original source.

The demonstrated consequences of venous congestion force us to admit, however, that *increased pressure may act upon the intertubular capillaries, and give rise to albuminuria*, just as obstruction of the veins elsewhere may cause dropsy, with which there would necessarily be albumen; but there is no evidence indicating that such is the case in diseases of the heart. We know that even greater pressure may be exerted without albuminuria.

Dr. Osler (64) has just reported a remarkable case of obliteration of the inferior cava between the diaphragm and renal veins, in which there was no albumen, although there was ascites and great congestion of the vessels of the cortex and medulla, while the veins about the bases of the pyramids were remarkably large.

Should it be urged that congestion may act indirectly, by exciting swelling of the cells and intercellular tissue (58, p. 426), it may be answered that such changes are certainly often wanting, and when present

are not necessarily associated with albuminuria (35, p. 226).

The result of this inquiry being most unsatisfactory, *the agency of the congestion of the intertubular veins being evidently inadequate to account for most cases of cardiac albuminuria, we have still to seek the cause in the remainder, and naturally ask whether the glomeruli yield albumen under increased tension*.

We have learned that the arrangement of the intertubular veins is not such as to favor transudation. If, on the other hand, we examine the minute anatomy of the glomeruli, we see bodies apparently constructed to promote the escape of fluid, while the extremity of the tubuli seems especially contrived to receive. All theories of the present time correspond in regard to filtration through their delicate walls (35, p. 46), and it seems clear that the quantity increases with the increase of pressure. But even if this view be correct, *can we show that albumen escapes here also?* Though there are great differences of opinion in regard to this matter (35, p. 46), there is good reason for believing that such is the case. But it is not proved that its appearance or amount depends upon increased pressure.

In regard to the first point, the escape of albumen, the investigation is attended by great difficulties. The most satisfactory results have been obtained from experiments on the frog, the arrangement of whose renal vessels is exceptional, there being an additional vein which conveys the blood from the posterior part of the body to the intertubular capillaries, as the *vena porta* of the liver conveys the blood to that organ. Availing himself of this peculiarity, Nussbaum (78) tied the renal artery of the living animal, injected from the heart, and found that though the intertubular veins were filled, the glomeruli were not (84, p. 141). Under these same conditions an injection of egg albumen was not followed by albuminuria, which occurred, however, if the artery was free. The injection of an amount of egg albumen, which was borne perfectly well by the animal in his natural condition, proved fatal in a few hours when the renal artery was tied (85, p. 584). Other substances injected at the same time appeared in the urine, while the albumen did not, showing a selective power in different parts of the kidney.

The experiments of Ribbert (95), though not altogether satisfactory, seem to show that, after interrupting the circulation in the renal artery, exciting inflammation of the kidney, injecting egg albumen, and then hardening the organs in alcohol, albumen was detected between the glomeruli and capsules, but also in the tubules.

Litten examined kidneys after the renal artery had been tied two hours, and found albumen in the capsules, with a smaller amount in the tubuli of the cortical substance; but the quantity was much less than when the vein was tied (103, p. 162). If the artery were tied from a quarter to half an hour only, the quantity of albumen was much larger (103, p. 163).

Having made it reasonably certain that albumen may escape through the glomeruli, *can we show it to be equally true that it passes under increased pressure?* Such is not the case in simple hypertrophy (35, p. 236) nor in aortal regurgitation (35, p. 59). Many experiments have been performed, resulting in increased pressure on these bodies, without the appearance of albumen (28, p. 155), unless the tension were such as to cause rupture and extravasation of blood. The aorta has even been tied below the origin of the renal

artery without the supervention of albuminuria (35, p. 256), and if both carotids were tied the result was the same. Recalling in this connection the fact that albumen appears in the urine in cardiac disease when the power of the heart has failed more or less, that in the cyanotic kidney the glomeruli are not distended, are we to conclude that the albumen escapes from the intertubular veins, and that the Malpighian bodies are in no way concerned, although we have shown that albumen generally escapes through them?

Before deciding this we must inquire into the physical laws which regulate the passage of albumen through membranes; for, notwithstanding the assertions formerly made to the contrary, it is now admitted that such a passage does take place (11, v. 44, p. 122). Though these laws are understood but imperfectly (35, p. 42), Runeberg's experiments show that solutions of albumen are only emulsions, which pass through membranes more or less readily, according to their character. The particles of albumen behaved like those of casein in milk when epithelial membranes were used. Water and soluble salts passed through, while casein did not. But this permeability depended upon the character of the membranes, albumen passing readily through those of the density of the capillary walls, while it was arrested by epithelial membranes (35, p. 47). But the changes incident to varying pressure always took place gradually (35, p. 43), an important point to remember in comparing these with other experiments. *Contrary to what was usually taught, he ascertained that the permeability was greater under low pressure than under high.* The same law was manifested if fluid were present on both sides of a membrane, a diminution of the difference in pressure being followed by increased permeability (35, p. 43). But objection may well be made, and is made (28, p. 156), that the walls of the vessels do not act in the same way as physical membranes in this connection. Runeberg asserts, however, that they do. Capillary vessels allow albumen to pass through, while epithelial membranes do not, though permeable to water and soluble salts, as shown in the secretion of tears and sweat (35, p. 46).

Experiments on living tissues seem to demonstrate the same law. Tying the renal artery furnishes us with the proof that diminished pressure of the blood in the glomeruli is followed by albuminuria (11, v. 45, p. 26) (35, p. 57). This may take place even when, on opening the clamp, the pressure is less than under normal circumstances, while the circulation certainly continues, and there is no evidence of any stagnation of blood in the vessels beyond the glomeruli which might cause pressure. The arrest of the movements of the heart, by inflating a bladder introduced within it, was followed immediately by the appearance of albumen, which disappeared in about an hour and a half (35, p. 235).

Cohnheim has shown that the permeability of the wall of a blood-vessel is increased by obstructing the flow of blood through it. When the blood is again let on, a more albuminous fluid transudes than when the veins were obstructed, the globules themselves even escaping (35, p. 263).

Taschenoff found that in poisoning by curare the blood pressure was much diminished and the white blood corpuscles passed through the walls of the vessels (35, p. 264).

Litten (103, p. 164) noticed that in animals poisoned by strychnia albuminuria followed the relief of the

spasm of the arteries, but diminished rapidly as the effects of the drug passed off. An examination of the kidneys while the vessels were contracted and no urine was passed showed the capsules empty, while after the appearance of the albumen they were filled with an exudation. If the ureters be tied so that the urine accumulates in the tubuli, and consequently exerts pressure upon the glomeruli, thereby diminishing the relative difference between the external and internal pressure, albumen makes its appearance (11). As still further evidence of this effect we may cite the fact that the fluid which accumulates first after tapping in ascites contains less albumen than the larger quantity which compressed the blood-vessels (35, p. 263).

To what conclusion does this evidence bring us?

We have seen that when general venous congestion reaches a certain point albumen may make its appearance; that obstruction of the renal veins, by disease or experimentally, is also followed by albuminuria; but we have not shown that the venous tension in cardiac disease even approximates to that of the above conditions, or is sufficient to produce similar consequences, while we have shown that very great pressure may be exerted on the blood in the renal veins without the supervention of albuminuria, and that in cases of obstruction where such has appeared there are other changes in the kidney, far beyond mere congestion, and that true renal disease may be present. We must also add that in some instances, after dropsy has supervened in other parts of the body, the kidneys would be very likely to participate in this, and furnish to the urine a certain amount of albumen, just as the latter may, perhaps, render the saliva albuminous when there is dropsy in some cases of Bright's disease (83); *we have not, therefore, proved that the albuminuria of cardiac disease is the consequence of congestion, and still less of congestion of the intertubular veins.* To assume the last would be to assume that, under the conditions involved, albumen escapes through the capillaries, which usually oppose its passage, while the common route through the glomeruli is avoided. On the other hand, *we have the most direct proof that the diminution of the pressure in the Malpighian bodies is, under various circumstances, followed by albuminuria,* where no other change can explain it, but such a result is not inevitable, either with diminished pressure or extreme oliguria (97, p. 356). Though Litten attributes the escape of albumen to *dilatation of the vessels of the capsules* (103, p. 163), and thinks it less dependent upon variation of pressure than has been assumed, he admits that his own results do not conflict with those of Runeberg, the advocate of diminished pressure, as the blood moves more slowly in dilatation, and is, consequently, in contact with the wall of the vessel a longer time (103, p. 166). *This dilatation of vessels, with diminished rapidity of the circulation, certainly merits the fullest consideration.*

AFFECTIONS OF THE NERVOUS SYSTEM.

We now come to another class of cases, in which the simplicity of the phenomena and the temporary character of the albuminuria seem to offer an inviting field for investigation, namely, the affections of the nervous system. In considering the physiological and pathological data upon which rest the conclusions in regard to the connection of albuminuria with impressions produced upon the nervous system, it is very difficult to separate this influence from others acting at the same

time. We shall therefore first give the *evidence furnished by physiological experiments*, as clinical cases are rarely, if ever, so free from complications as to permit the reference of the albuminuria to a single exciting cause. These effects are so immediate and transient, we can hardly attribute them to a change in the blood or the tissue of the kidney, but rather to *some modification of the action of the heart or blood-vessels* (35, p. 247) *through the influence of the vaso-motor nerves, which probably implies some variation of pressure* (35, p. 59). Such a variation may depend upon dilatation of arteries through paralysis, or contraction of the same through cramp (35, p. 242).

Let us first consider the *general principles* shown by the disturbance of the circulation through the vaso-motor nerves. The pressure of blood in the capillaries of the kidneys is greater when the force and frequency of the pulsations of the heart are increased, or when the small arteries in parts of the body other than the kidneys are contracted. If the renal artery itself is relaxed there is a diminution of pressure upon this vessel, but an increase on the capillaries beyond, provided other arteries are not also relaxed so as to form an enlarged reservoir for blood, which would prevent the increased pressure upon the capillaries of the first vessel. The effect will be greater if other arteries are constricted. If, on the contrary, the renal artery be constricted, the pressure in the capillaries is diminished, unless there is a compensating constriction elsewhere. The effect of this is increased by dilatation of other vascular areas (61, p. 278) and diminution of the general pressure of the blood, either through a failure of strength of the heart, or by general dilatation of the small arteries or of vascular areas not connected with the kidneys. Seeing that such changes in the blood-vessels may take place, *we must ascertain whether they actually do occur in the cases cited*. Let us first examine the phenomena accompanying the

SECTION OF THE SPINAL CORD BELOW THE MEDULLA,

which is followed by a great decline, perhaps a complete arrest, of the secretion of urine and albuminuria. By this operation the arteries of the body as a whole are cut off from their vaso-motor centre, and we have paralysis of the muscular coats with dilatation and diminished blood pressure. The increased capacity of the vessels prevents the distention of the capillaries. Though the renal arteries suffer with the rest, they bear so small a proportion to the whole, the lowering of pressure is very great (61, p. 279). If we have interpreted correctly the effects of diminished pressure, in considering the disturbances of the circulation, we have here also an explanation of the appearance of albumen after the serious lesion of the spinal cord. *But we have still stronger evidence to show how far the permeability of the walls of vessels may be thus affected.*

DESTRUCTION OF THE SPINAL CORD.—The experiments of Gergens (87, p. 591) prove that this not only is followed in a very short time by œdema, but by the appearance in the fluid of the latter of coloring matter injected into the heart, which did not escape from the circulating blood while the spinal cord was uninjured. The same results were obtained by poisoning frogs with large doses of curare, and introducing into the circulation granular matter, which appeared in the fluid of œdema as before (87, p. 595), with blood globules, though there were less of the latter than when the spinal cord had been destroyed.

These results were certainly not owing to increased pressure, as that was less than in health.

STIMULATION OF THE SPINAL CORD BELOW THE MEDULLA.—The same deficient supply of blood and lessening of pressure is seen in this, which causes such constriction of the small arteries as to render the kidneys pale and bloodless. At the same time the pressure on the larger arteries may be increased (61, p. 279).

IRRITATION OF THE RENAL NERVES.—The appearance of albumen is explained by the contraction of the minute arteries, which interferes with the flow of blood to the kidneys, the other arteries of the body not being affected, and therefore allowing the local action to exert its full power (35, p. 246). **SECTION OF THESE NERVES** does not produce albuminuria, because the pressure is not diminished as it is when there is general paralysis of the small arteries (35, p. 264).

Though the remaining direct lesions of the nervous system are not reported with such complete details as the above, they still seem to admit of a similar explanation.

PUNCTURE OF A CERTAIN POINT IN THE FOURTH VENTRICLE (59, p. 398).—In this, we have the same consequences as those which are noticed after the division of the spinal cord, namely, a diminution in the amount of urine and often albuminuria. We may fairly interpret in the same way the results of **LESIONS OF THE CEREBRAL PEDUNCLES** in animals (15).—of the **DESTRUCTION OF THE SPINAL CORD ON THE LEVEL OF THE LAST DORSAL AND FIRST LUMBAR VERTEBRÆ** (16, v. 2, p. 858).—of **IRRITATION OF THE POSTERIOR ROOTS OF THE LAST DORSAL NERVES** (16, v. 2, p. 859).—and of **SECTION OF THE VAGUS** (16, v. 2, p. 858).

RENAL DISEASE.

Thus far we have considered the more or less remote causes of albuminuria, the kidneys themselves not being diseased, at least not primarily. We have now to investigate the connection of albuminuria with histological changes in the kidneys. To avoid repetition, and present the various changes in as concise a manner as possible, we will enumerate briefly the modifications which the organs undergo in those forms of disease most commonly met with, such as the different varieties of nephritis and amyloid degeneration.

ACUTE PARENCHYMATOUS NEPHRITIS.—Without claiming that Bartels' division of nephritis into acute and chronic parenchymatous and interstitial is entirely satisfactory and final, as parenchymatous and interstitial may be combined (58, p. 437), it expresses with sufficient accuracy the principal differences and pathological changes to justify us in following it. A few cases have been reported which show that albumen may not be present at certain times in the course of this acute form of disease, though there be general anasarca; but in these few exceptional instances, both albumen and other unquestionable indications of nephritis have made their appearance subsequently (1, 9, p. 247). In regard to the quantity of albumen, there may be great variations, but the amount is never so large as in the chronic form,—never more than 0.5, frequently only 0.2. The statements of much larger amounts (20, p. 305; 21, p. 55; 14, v. 14, p. 291) must be taken with caution, as cases spoken of by some writers as acute might now be classed under the head of chronic. In fact, such changes have taken

place in the nomenclature of the varieties of nephritis within a few years as to make it impossible to compare the earlier with the more recent works in this respect. Still, if the quantity be large, we should always suspect some form of parenchymatous disease.

Though the appearances vary according to the stage in which the examination is made, we may state briefly that we have hyperæmia, as a rule opacity of the epithelium, swelling of the latter, sometimes sufficient to dilate the canals, and perhaps fatty degeneration. With this there is an exudation of clear serous fluid, and an accumulation of lymphoid elements in the interstitial tissue, followed, perhaps, by increase of the latter which may become two or three times as thick as usual (53, p. 636). The vessels of the glomeruli may be covered with nuclei, which fill the capsule (53, p. 646), or may be so thickened that their calibre is materially diminished (54, p. 99). Hemorrhage, though not constant, may occur both in the tubuli and capsules (51, p. 94).

CHRONIC PARENCHYMATOUS NEPHRITIS.—Though the amount of albumen may differ in different cases and in different periods of the same case, increasing in acute exacerbations, it is never absent, and is greater when the disease is at its height than in any other condition, at times reaching five per cent., but diminishing in secondary shrinking. As the chronic may follow the acute, it is evident that the changes must to a certain extent resemble those described above, but the processes are carried farther.

The changes in the tubuli are of the same character as those just described, but still more marked, the interstices between the canals being, perhaps, twice as wide as usual (53, p. 640), partly from swelling caused by fluid exudation, partly through the growth of the elements of the connective tissue or the escape of white corpuscles. The epithelium within the capsule may also occasionally increase and be accompanied by great diminution of urine (54, p. 92), while the walls of the glomeruli may be thickened, as previously described (54, p. 99).

INTERSTITIAL NEPHRITIS.—Albumen may be absent temporarily, or perhaps for a considerable time, but it is always found sooner or later, increasing as the disease makes progress, and declining toward the close. In one patient, in whom it was occasionally absent, there was great debility, and in three others the absence coincided with rest in bed (1 v. 3^d, p. 397). The amount is much less than in the other inflammatory processes, being hardly as much in a thousand as in one as in a hundred in the other. This holds good when the amount of urine diminishes towards the close (14). We must, however, except some cases in which convulsions have occurred, where the amount has been large, but here we have a special and additional agency at work. The essential lesion is the presence of an unusual proportion of connective tissue, owing either to an increase of the latter or to the disappearance of other structures (58, p. 426). The tubuli may be normal, or may gradually contract until they become impervious (53, p. 641), and the capsules of the glomeruli may undergo similar changes, being thickened and transformed into connective tissue, which surrounds the body as a broad, concentric ring. The afferent arteries may also be thickened, and form dense, solid cords. There has been described a thickening of the vessels of the glomeruli (38, 505), which may render them impervious.

AMYLOID DEGENERATION.—The amount of albumen is likely to be very small at the beginning, but increases gradually, though perhaps intermittently, varying from time to time, and finally becoming considerable (1, 9th, p. 464), and remaining so permanently. The change in some cases may be sudden and the quantity continue abundant, but then the amount of urine is always small. A sudden augmentation of urine will be accompanied by a diminution in the relative amount of albumen. The presence of the latter is so necessary that the diagnosis cannot be made without it, though a case is reported in which it was absent through the whole (20, p. 326).

The loops of the glomeruli are the first portions attacked (53, p. 672); then follow the afferent arteries, more rarely the efferent vessels and the cortical capillaries, and finally the arterie rectæ, in which the disease sometimes preponderates. The vessels increase in size, and their walls in thickness (1, 9th, p. 473), until, when the change is very marked, injections will not enter. Though similar disease may be noticed in the tunica propria and epithelium of the tubuli, or in the interstitial tissues, such is not the rule. The epithelium, however, may be opaque and fatty.

SUPPURATIVE NEPHRITIS.—This can be fully considered only in connection with its various exciting causes, which do not concern us here. The lesion consists in an inflammation of the intercellular tissue. The changes are of course similar to those previously described, terminating in the formation of pus corpuscles. Even then the amount of albumen may be small (58, p. 246). It is hardly necessary to add that where blood and pus escape into the urinary passages albuminuria must be more or less marked.

Having acquired this knowledge of the various changes which take place in the epithelium of the tubuli and capsules, in the intertubular tissue and the blood-vessels, we have still to consider their separate agency in the production of albuminuria.

CHANGES IN THE EPITHELIUM OF THE TUBULI AND CAPSULES.

These may act in various ways, either through the circulation, or independently of the latter, which may remain normal.

(a.) They may produce a mechanical effect upon the blood-vessels through the pressure necessarily connected with their enlargement. (b.) According to Johnson (33, p. 242), they may interfere with the circulation by a suspension of their normal activity, which implies a cessation of that natural interchange of elements which is supposed to favor the movement of the blood. (c.) If it be assumed that, under normal conditions, albumen escapes through the glomeruli and is afterwards absorbed by the epithelium, the disease of the latter may prevent this action, and allow the albumen to escape with the urine. (d.) The cells may, after taking up the albumen in any way, yield it again to the passing current of urine. (e.) The cells, being diseased, may secrete albumen. (f.) The albumen may be the product of the dissolution of cells. (g.) The natural position and condition of the cells preventing the escape of albumen through the membranes they cover, their disease or absence might allow such a translocation to take place. (h.) By obstructing the tubuli, they may prevent the escape of urine, and thus diminish the inner tension on the glomeruli.

Let us now consider these points in detail.

(a.) **PRESSURE ON THE BLOOD-VESSELS.** — The increased size of the kidneys suggest an increase of tissue rather than of blood, especially where the organs are pale. A number of writers have considered this swelling as an important agent, and some as the agent, in the production of albuminuria. Senator (33, p. 502), among the former, and Bartels among the latter, regard diffused affections of the kidneys as causes of transient or permanent albuminuria by this interference. The enlargement of the tubuli, when crowded with their contents, is very noticeable, and it would seem that this must necessarily be followed by more or less compression of the adjacent vessels, though it may be difficult to appreciate the exact effect upon any particular vessels, or restrict it to them.

(b.) **CONGESTION CAUSED BY A FAILURE OF CELLS TO ACT UPON THE BLOOD.** — Johnson asserts (33, p. 242) that the urine does not become albuminous, nor is there evidence of great congestion until the cells are so far destroyed as to interfere with the performance of their functions. This will hold neither as a fact nor as a deduction. We have already cited a number of instances in which the urine has been decidedly albuminous without any visible change in the cells, and it has not been shown that congestion is necessary for the production of albuminuria. In regard to the point that the circulation ceases when the cells have been destroyed, the latter may have disappeared owing to a deficiency of nourishment from disturbance of the circulation.

(c.) **ABSORPTION OF ALBUMEN BY CELLS.** — The view that albumen always escapes from the Malpighian bodies under normal conditions, and is afterwards absorbed by the epithelium, is plausible, and we may explain most, if not all, the cases of albuminuria by assuming that where it appears in the urine the cells have been unable to perform their usual work, owing to disease, or that when in a normal condition they are unequal to the demand which excessive filtration makes upon them (28, p. 154). But it is very difficult to believe that the cells would ever be equal to their work, if we accept Ludwig's calculation that, with a great flow of urine, from three hundred to four hundred grammes of dry albumen must be absorbed every twenty-four hours (35, p. 49). Still less favorable to this view is the fact that the amount of albumen is not in proportion to the extent of the degeneration in the cells (35, p. 71). On the contrary, it diminishes both in per cent. and in absolute quantity in the most advanced stage of disease, when the epithelium is changed as much as possible (35, p. 64), and many observations show that the cells may degenerate and be destroyed without albuminuria occurring. But more direct evidence is furnished by Litten's experiments (103, p. 162), which seemed to show that albumen did not escape from the glomeruli in health.

(d.) **YIELDING ABSORBED ALBUMEN BY CELLS.** — The epithelium has been supposed by some to play an important part in the causation of albuminuria, by giving up albumen which it has absorbed, but such a supposition is not supported by any fact (1, v. 9, p. 58).

(e.) **THE ACTION OF EPITHELIAL CELLS AS SECRETING ORGANS.** — This action is very difficult to appreciate, but we must remember that the cells certainly form no albumen in their normal state, and such action can only be studied as a result of disease. The only reason for attributing to them this singular function is

that the albumen appears very frequently at the same time that they undergo certain visible alterations. We must first determine *whether some lesion in these is necessary in order that albumen may make its appearance*, or, if such is not absolutely essential in all cases, whether there is not, at times, some special modification which can be recognized as directly connected with this result. In regard to the first point, that some change always exists, we are told by Cornil (66), Johnson (33, p. 241), and Spring (16, v. 2, p. 856) that such is found. Even if it be true, as Cornil asserts, that hyperemia alone may cause changes in the cells, such as opaque swelling or fatty degeneration, there is no proof that hyperemia is always present, and good reason for believing that in some instances the opposite is true. Moreover, we have abundant evidence of the appearance of albumen where it seems impossible that the cells should be diseased, the appearance and disappearance of the albumen is so rapid, as in intermittent fever, mere change of position, exertion, or epilepsy (35, p. 63). Bartels (1, 9) states decidedly that *albumen may be found in the urine during life when no histological change can be detected in the kidneys after death, either in the cells or interstitial tissue*.

Having thus shown that albumen may be found where there is no histological change, we have next to inquire *whether it always appears when such a change is present*. There is abundance of evidence that it does not. Bartels and Rosenstein declare (1, v. 9, p. 49) that *there may be extensive fatty degeneration without albuminuria*, and the former adds that the same exemption is noticed where, perhaps, both cells and intercellular tissue are much diseased. The cases of rapid fatty degeneration under the temporary influence of phosphorus, arsenic, and sulphuric acid are very valuable, as the structural changes are much simpler than those of ordinary nephritis, in which the circulation is necessarily much deranged (11). Although the introduction into the system of these agents may be followed by acute nephritis, the morbid process may stop short of this, or the change may be so slight as to make it easy of comprehension. According to Runeberg (35, p. 257), albuminuria in poisoning by phosphorus is by no means the rule, and, when it occurs it is in the later stage, in connection with diminished activity of the heart, weak sounds of the same, and frequent small pulse. Yet we have here marked fatty degeneration (35, 257). Stockvis states that in clinical cases of phosphorus poisoning but an extremely small quantity of albumen has been found, and in some instances none at all, where there was marked fatty degeneration of the epithelium. This was confirmed by his experiments (11, v. 45, p. 438), in which no albumen was seen, although the degeneration was striking, after a dog had been fed with large quantities of phosphorus.

We have shown that such *morphological changes are not necessary for the production of albuminuria*, and that *they may be present when the latter is absent*, though we have not proved that they play no part; and it is impossible to do so; but we are justified in concluding that, if they have any agency, it is not essential. If there be any special lesion of the epithelium connected with the formation of albumen, we cannot say what it is. The most careful microscopic tests can show no change in the cells which is characteristic of the cases in which albuminuria has been seen during life. Rune-

berg (35, p. 63) sums the matter up very concisely, saying, The granular infiltration of epithelial as well as the endothelial cells of the vessels is as marked in cases where there has been no trace of albuminuria, and *vice versa*. Where there has been albuminuria, the change may be inconsiderable or absent.

(f.) DISSOLUTION OF CELLS.—Though the presentation of this as a cause implies the advancement of certain views which, if more or less plausible, are hardly more than conjectures, we will, for the sake of completeness, speak of it very briefly. Senator (38, p. 478) suggests that the cells of the tubuli might be transformed into albuminous matter and dissolved in the urine, although he admits that in cases where the destruction of cells is most marked, as in poisoning with phosphorus, and in acute atrophy of the liver, or in small-pox, no albumen may appear.

The various statements made are not such as to convince us that albumen is derived from the dissolution of cells; they can only be regarded as hypotheses.

TRANSDUDATION OF ALBUMEN OWING TO DISEASE OR ABSENCE OF EPITHELIUM.—We have seen in the experiments of Runeberg that the presence of epithelium makes a great difference in the transudation of certain elements dissolved in fluids, and it is reasonable to suppose that the presence of epithelium on the surface of the tubuli and Malpighian bodies serves rather to prevent the escape of albumen, as the arrangement of the blood-vessels is such as to favor it. *It is not improbable that such should transude when this epithelium is diseased or absent* (14), just as we see exudations on the surface of the skin when the epidermis is lost (16, v. 2, p. 857).

DIFFERENCE OF PRESSURE IN THE GLOMERULI AND TUBULI. We have already spoken of the doubtful character of the cases in which obstruction of the ureter has been followed by albuminuria, as other agencies than mere obstruction may be operative, but the results of experiments make such an agency appear very probable. Thus, tying the ureters has been succeeded by albuminuria, attributable, it seems, to the equalization of the pressure on the two sides of the capsule, and of course diminishing that on the inside. But this result may admit of another interpretation, namely, that the distention of the tubuli increased the blood pressure in the veins (35, p. 59).

Runeberg, in his experiments with gummi gutti emulsions found that no particles passed through under a certain pressure; but the escape of the fluid after it had filtered through being prevented, so that it exerted a backward pressure, the particles transuded (35, p. 241). The same result may follow congestion of the intertubular veins, such as is seen in compression of the renal veins and of the vena cava, above the opening of the latter (35, p. 229). This congestion, by compressing the tubuli and interfering with the discharge of their contents, tends to equalize the pressure on the two sides of the glomeruli. This condition is not hypothetical, but is observed in a microscopic examination of the kidneys, which shows not only the veins dilated, but the canals narrowed. It is also made to appear very probable by the experiments of Ludwig, who found that a solution of gum and salt, forced into the renal artery under strong pressure, escaped through the veins, while the fluid was allowed to flow from the ureter. If, however, the veins were tied partially or wholly, the flow through the ureter diminished or ceased altogether, although the pressure on the ar-

tery was the same. The flow was reëstablished when the compression of the vein was relieved (35, p. 231). Even if the vein were only partially closed, so that the blood continued to flow, though with less pressure, the result was the same.

The filling and obstruction of the tubuli by the diseased cells might well have the same effect. It may be that the accumulation of uric acid in the tubuli of the kidneys of new-born children acts in the same way, by interfering with the escape of the urine (47, v. 1, p. 148).

Compression of the glomeruli by an accumulation of cells in the capsules. We have described such a multiplication of cells in connection with acute and chronic nephritis. It is difficult to estimate the effect of this on secretion, for there are other changes in the kidney, the precise agency of which we cannot appreciate (54, p. 100). But that it plays a part seems very clear, as, where it has been found, the quantity of urine has diminished very much. In one case it fell to three hundred cc. (54, p. 95), and we may have complete suppression (53, p. 646). In a case of granular atrophy where it was found there was much albumen, although the quantity is usually small (54, p. 100). If the albuminuria were dependent either upon this accumulation of cells within the capsule or a change in the capillaries themselves, the former must have been the active agent, as the greater part of the capillaries of the glomeruli were normal (54, p. 96).

CHANGES OF THE INTERSTITIAL TISSUE.

These must play an important part, whether there be increase or diminution. The *albuminous fluid* formed in connection with inflammation, as in other parts of the body, *may transude into the canals and escape with the urine* (14), constituting, probably, a *very important element* in the causation of albuminuria. It is in such cases that we have the largest amount of albumen.

The marked changes in interstitial nephritis must exert a great effect on the circulation, but it is difficult, if not impossible, to show that the action of the dense tissue is confined to any special set of blood-vessels, and the amount of albumen is so small as to suggest the atrophy of many of the glomeruli (33, p. 245).

(To be continued.)

RECENT PROGRESS IN ORTHOPEDIC SURGERY.

BY E. H. BRADFORD, M. D.

REST OR MOTION IN THE TREATMENT OF JOINT DISEASES.

THIS subject has been under discussion before the Society of Surgery in Paris during the last six months of the past year. Both sides of this question have been well presented. M. Verneuil, in an able paper, states his opinion that the dread of ankylosis leads surgeons to a great deal of bad practice. "He opposes with all his power this 'anchylophobia' and the practice of passive motion." He denies that a single fact can be cited in the whole science of surgery to prove that prolonged and continued rest has caused ankylosis of a healthy joint. Certain experiments have shown that absolute rest has caused a thinning and

alteration of the cartilages of the joint, a limitation to motion, a diminution of the amount of synovial fluid; but these experiments and the autopsies which are quoted he does not consider convincing, and not sufficiently reliable to counterpoise the testimony of many cases of perfect recovery of motion after prolonged rest. In diseased joints ankylosis sometimes occurs after prolonged rest, but this Verneuil thinks is not a result of the treatment, but in spite of it. Ankylosis is due to the contraction of the periarticular muscles, reflex from the irritation at the joint. He makes a distinction between mechanical rest produced by devices for immobilization and that which is produced by the action of the surrounding muscles (immobilization active). This latter is in the end destructive to a joint, and the tendency of this muscular spasm is to increase the pressure of the diarthrodial surfaces. The former is effective in diminishing muscular contractions and the destructive changes which accompany them. Ankylosis is the result of several causes; inflammation is one of them. It is absolutely certain that rest is an antiphlogistic of the first order, and it is illogical to think that it produces precisely the effect (that is, ankylosis) the cause of which it combats successfully. Passive motion as a preventive to ankylosis Verneuil thinks is useless in cases where stiffness is not likely to be permanent, and powerless where ankylosis is likely to be established, and in many cases certainly dangerous. The treatment advised by Bonnet and Malgaigne, of occasional passive motion during the treatment of prolonged immobilization, he regards as unnecessary. Ankylosis is not liable to occur in all articular affections, and is a rare termination; the exaggerated dread of this has given rise to two important faults of treatment, namely, too early discontinuation of mechanical rest and commencement too early of passive motion. Motion which can be employed in treating arthropathies is either, first, passive or artificial; second, physiological or active, as he terms it, that is, by muscular action, voluntary or involuntary. Passive motion should be reserved for the correction of existing deformities, but never be employed to prevent them; but the second method, active motion, when employed at the proper time, is very useful, and will in the end restore the articular functions to a remarkable degree. The two chief agents for treating joint affections are artificial immobilization and natural motion,—the first to attack the pathological lesion, and the other to bring about the physiological restoration of the affected parts. The only purely surgical methods at our disposal (excluding mechanical rest) to combat the progress of articular inflammation are continued extension and preventive excision.¹

M. Desprès believes that the theory of absolute rest was carried too far by Verneuil, and cited cases cured by bone-setters as an illustration; in white swelling, osteitis of the epiphysis, and in arthritis during the painful stage, immobilization should be used at first. When, however, motion is spontaneously made by the patient, this can be allowed with precaution. Articular stiffness after fractures requires passive motion after a short period of complete rest. In fracture at the elbow Desprès never immobilizes.²

M. Le Fort³ disagrees with Verneuil in the opinion

that immobilization does not injure a healthy joint, and mentions cases of fracture which showed the contrary. He believes in the use of passive motion after the acute inflammatory stage has passed. He does not advocate the employment of passive motion by the hands of the surgeon, but the use of instruments of feeble action, exercising a continuous and slow motion by means of rubber straps.

In regard to white swelling, certain forms of inflammation occur in certain joints. Fungus arthritis is more frequently found at the knee, elbow, and ankle. Ankylosis is the result of one mode of cure, and immobilization is the treatment. M. Le Fort does not try passive motion after the recovery, and believes ankylosis should be respected. In coxalgia, however, motion is a basis of treatment. At the hip and shoulder joint fungus disease is rare. When there is severe pain he immobilizes his patient, using also permanent extension, and no motion should be allowed while there is pain. He first employs slow extension to rectify a faulty position if any exists, then applies an extension splint while the patient walks.

PAINFUL AFFECTION OF THE FOOT.

In the *American Journal of the Medical Sciences*, January, 1876, Dr. T. G. Morton, of Philadelphia, described an affection hitherto overlooked in surgical literature. He has recently collected and reported a few additional cases. The disease is characterized by intense pain localized in the joints of the third and fourth metatarsophalangeal joints. Females are not more frequently affected than males, nor the right foot than the left. Swelling is seldom present. Most cases result apparently from injury, as a sudden twist of the foot in walking, especially on rough roads. Any exercise which may suddenly displace the toes when confined by a shoe may produce the trouble. Nothing abnormal is to be found in the joint, and on section through the bone the parts are seen to be normal. According to Dr. Morton, the cause of the trouble is the anatomical relations of the metatarsophalangeal joints. The first, second, and third metatarsophalangeal joints are on a line, but the head of the fourth metatarsal bone lies one eighth to one fourth of an inch behind the head of the third, and the head of the fifth lies three eighths of an inch behind the head of the fourth. The joint of the third is slightly in advance of the joint of the fourth, and the joint of the fifth is considerably behind the joint of the fourth. There is slight lateral motion at the first three metatarsophalangeal articulations; this is greater in the fourth and fifth. Lateral pressure brings the head of the fifth metatarsal bone and the phalanx into direct contact with the fourth metatarsophalangeal articulation, and to a certain extent the extremity of the fifth metatarsal rolls above and under the fourth. This gives an opportunity for bruising the digital branch of the external plantar nerve, and it is to this that Dr. Morton ascribes the pain. The treatment should consist of rest at first with the foot elevated, anodyne applications, and perhaps local blood-letting. A narrow flannel bandage can be applied around the foot to give moderate support to the toes. After the subsidence of the pain, the patient can be allowed to go about, but should wear a shoe with a thick, broad sole. A thin-soled shoe is not to be used. The shoe should lace, and in some cases should open beyond the irritable joint. There should

³ Gazette hebdomadaire, December 5 and 12, 1879.

be no lateral pressure on the toes, so that the foot may spread in walking. In one case no treatment was of service until the excision of the fourth metatarsophalangeal joint. Perfect recovery with an entirely useful foot resulted.¹

CHRONIC DISEASE OF THE KNEE.

In the last Report on the Progress of Orthopedic Surgery,² the views of many modern surgeons were mentioned in support of the opinion that the so-called joint diseases were *primarily* not joint diseases, but affections of the epiphyses of bone in close proximity to the joint. Dr. Berry,³ forming his opinion from the clinical observation of thirty cases of knee-joint disease, inclines to this view. He believes a primary inflammation of the synovial membrane in children to be almost invariably of an acute nature; true articular osteitis is always chronic. "Formerly the type of disease which is known by Virchow as osteomyelitis, and by Nélaton as tuberculous osteitis, was not so fully recognized as an aetiological factor in chronic articular affections, most authorities locating the primary changes in the synovial membrane."

The opinions of Volkmann,⁴ Schüller,⁵ Smith,⁶ La Sègne and Duplay,⁷ and Mac-Namara,⁸ are mentioned in support of the theory of the bony origin of these joint affections.

Sometimes in knee-joint affections the morbid changes result in the formation of pus, which manifests itself quite late in the affection, and is seen external to the joint, usually above the condyle of the femur, the tumor dissecting its course upwards between the tissues of the limb, often as high as the upper third. Absorption may take place, but as a rule it will discharge itself spontaneously. The constitutional disturbance is ordinarily slight. In other cases the osteitis near the joint invades the joints and excites an acute inflammation. This is, however, a process of many months' duration. The existence of subluxation, apart from other evidence, is not pathognomonic of disease of the bone, for any degenerative process about the knee-joint would produce the same result. There is enlargement of the bone, most frequently of the internal condyle. In many cases where during life there had been infiltration about the joint, which alternately improved and relapsed, at autopsy no evidence of caries was found on the surface of the bone, but on section of the condyles caseons and purulent degeneration was discovered in the bone.

Dr. Berry did not find that the diminution of irritability to the faradic current in the muscular tissues about the joint in bony disease, and the normal condition in purely synovial affections which has been stated to be of value in diagnosis, were reliable for that purpose.

In regard to treatment, Dr. Berry mentions that many cases where the limb was flexed firmly at the knee, with apparently no hope of future motion, gained ground in mobility under the influence of continu-

ous extension, so that locomotion was comparatively easy.

REFRACTURE FOR DEFORMITY FROM BADLY UNITED FRACTURES.

Dr. Roberts⁹ has collected the cases recently coming under his observation of refracture for this class of deformity. The objections usually urged against this mode of procedure are the dangers of fracturing at a point below the callus, the possibility of non-union, and the usual surgical complications of sloughing of tissue, erysipelas, etc. Non-union is not known to have occurred after refracture. There is, according to Dr. Roberts, no danger of fracturing at a point other than the site of the former fracture, if it is possible to fracture at all. After complete ossification it is true that the united bone may be as strong as, if not stronger than, normal bone; but the time needed for this is quite long, and before perfect ossification has taken place the point is weaker than any other part of the bone. Dr. Roberts does not think it possible to fracture sound bone by manipulation with the use of force which can be applied, and he supports his opinion by experiments in attempting to fracture sound bone. He concludes, therefore, that where it is possible to refracture at all, the seat of the fracture will necessarily be at the original break. Cases which are suitable for refracture are those where locomotion is prevented or impeded by the deformity, or where pain is caused by the displacement. The most favorable cases are of course those where fragments have united at their extremities, but not in the same line. Where there is union by lateral apposition of the fragments, it has been thought that refracture is impossible. Dr. Roberts is not of this opinion. In attempting refracture the force should be applied in such a way as to bring transverse strain upon the uniting fibro-cartilaginous union. If the bones are lapped, with the anterior surface upon the posterior surface, the power should be from the side. If the union is simply from lapping, with one side against another, the force should be directed from before backward. The easiest way to fracture is with the hands, placing a hard pad as a fulcrum. In order to avoid injuring the joints, and at the same time gain leverage, in fracture near the joint, splints can be bandaged along the limb over the joints. Where more power is needed a screw force can be employed, and in some cases it may be advisable to drill the bone before the use of force. In breaking a badly united fracture of the femur, of six months' standing, powerful extension was applied before sudden direct fracturing force was used upon the convexity of the deformed thigh. The patient was twenty-nine years old, and two and three quarters inches shortening existed. Cure was effected, with only one quarter inch shortening. The duration of the treatment was only ten weeks. To arrange for powerful extension with a compound pulley in this case, a flat plate was bandaged to the thigh, with a hook at the lower end, into which the cord could be fastened. The plate was furnished with a ridge on the sides, serrated by deep notches. A cord wound around the plate and the thigh closely bound them together, and enabled the employment of a great deal of force.

The results in all the cases reported by Dr. Roberts were thoroughly satisfactory.

ASYMMETRY OF LIMBS.

Dr. Morton has examined the length of the lower extremities in 513 boys from eight to eighteen years old. In 272 there was inequality; 91 showed a difference of one eighth of an inch; 100, one fourth; 41, three eighths; 22, one half; 12, five eighths; 2, three fourths; 2, one and one eighth; 1, one and five eighths. One boy, eleven years old, was found to have three and one fourth inches shortening without being aware of the fact. He had sustained a fracture of the femur several years before. In the other children no injury or disease could be traced. Measurements were not made by means of the tape, but by the apparatus devised by Dr. Stacy B. Collins.¹

CLUB-FOOT.

The best recent paper on the subject of treatment of club-foot was published in the JOURNAL² by Dr. Buckminster Brown. An abstract of this will not be needed by the readers of the JOURNAL.

Dr. Morton, of Philadelphia,³ reports the use of a "foot crusher" in the treatment of old, relapsed, and adult cases, where all treatment has failed. This is of simple construction, and its application, which has to be frequently repeated, appears to be unattended with danger. By its means the bones of the foot, tenotomy having been performed, are gradually forced into position. He does not advise tenotomy in infants, and thinks the operation is not necessary. He, however, admits that the treatment in children under six months of age is unsatisfactory, and should be mainly conducted by manipulations by the hand of the nurse.

Dr. Reeves⁴ advocates what he terms the "rapid treatment of club-foot." This consists of plaster-of-Paris bandages and tenotomy, when needed, with the rectification of the deformity, and immediate application of plaster-of-Paris bandages.

Hospital Practice and Clinical Memoranda.

A CASE OF MALIGNANT DISEASE OF THE UTERUS.

BY F. GORDON MORRILL, M. D.

THE following brief notes are offered as possibly throwing a little light on a somewhat rare form of uterine disease.

December 6, 1878, I was asked to see Mrs. X., aged sixty-three, whose history previous to the commencement of present trouble (with the exception of a miscarriage and consequent pelvic cellulitis fifteen years before) is unimportant. In August, 1878, her attendant noticed for the first time a purulent discharge from the vagina, at times tinged with blood, and on inquiry ascertained that she had suffered from pain in the region of the uterus for some weeks. I may remark here that the patient was a lady of most amiable and patient disposition, and rarely complained of anything which affected her personal comfort only. This discharge and pain continued up to the date of my first visit, when inability to sleep on account of the severity of the latter symptom had excited alarm. On examination induration of the cervix and impaired mobility of the uterus were apparent. A small polypus, which grew from the inner surface of the anterior lip, and hung down into the vagina, was twisted off, and its base enterized. Warm vaginal douches and opiate suppositories were prescribed.

December 22d. Pain so severe as to require a grain of morphia subcutaneously every twenty hours. Dr. Baker saw the patient in consultation with me, and the conclusion arrived at was that the case was one of malignant disease, although the os presented nothing characteristic. During the next six weeks the symptoms were pain, progressive emaciation, and slight hæmorrhage. Constipation was also added to the already existing train of evils, and was treated with tamar at first, and later with means of which I shall speak before concluding. The uterus had now become fixed, and examination per rectum discovered two hard nodules in its posterior wall, the larger being apparently the size of an English walnut. Up to the middle of April, 1879, all symptoms increased in severity; morphia was given to the extent of five grains daily by means of the hypodermic syringe, every form of opiate administered by the mouth causing instant nausea. The tamar now ceased to act, and large rectal injections failed to relieve, besides causing intense pain. Various internal medicines were tried, but all proved inert and nauseating. Finally a tablespoonful of glycerine in a tumblerful of warm water was thrown into the rectum, and with the happiest possible result. The rectum had become so far encroached upon by the growth in the posterior wall of the uterus as to require the use of a French elastic perforated bougie in injecting. For some years previous to her present illness the patient had lost all taste for ordinary solid food, and her diet consisted almost exclusively of cream, coffee, Bass's beer, and occasionally a milk biscuit. She continued this same diet throughout her sickness, and the disproportion between the small amounts of nourishment taken and the excretion as shown by the discharges brought away daily by the glycerine was almost startling, the latter being large even for a person in robust

¹ Dr. T. G. Morton, Surgical Report, Pennsylvania Hospital.² 1879, ci. 715-720.³ Surgical Report, Pennsylvania Hospital.⁴ Medical Times and Gazette, 1879, ii. 475.

health, with a vigorous appetite. I have noticed this fact in other cases of wasting illness, and know of no theory to account for it. The glycerine never failed to act satisfactorily, and usually within fifteen minutes.

May 1st. There was now no discharge whatever from the vagina.

June 15th. The patient's condition was most pitiable, and no less than *eighteen grains* of morphine subcutaneously and one hundred drops of laudanum per rectum were required daily to ease her pain; and even then the amount of comfort obtained was only comparative, and she got but little sleep.

On the 22d the pain suddenly ceased without apparent cause, and several hours of quiet sleep ensued. From this time very little morphine was used up to the date of her death, which occurred July 1, 1879, the immediate cause being evidently an old heart trouble. There was no autopsy, but the history, including age, long-continued pain, and absence of broken-down tissue, points quite distinctly to spindle-celled sarcoma.

Reports of Societies.

PROCEEDINGS OF THE BOSTON SOCIETY FOR MEDICAL OBSERVATION.

FREDERICK C. SHATTUCK, M. D., SECRETARY.

FOREIGN BODIES IN THE EAR.

FEBRUARY 16, 1880. DR. J. O. GREEN said that, a discussion having recently taken place in the society on the extraction of foreign bodies from the meatus auditorius, he would like to defend a possible method of extraction proposed by Von Tröltzsch and severely criticised by Professor Gross. The former has suggested the possibility of detaching the auricle from the bone behind the ear, and thus reaching a foreign body in the depths of the meatus after the failure of other means. The operation has never been performed as yet, but Dr. Green showed by a temporal bone that the upper wall of the osseous meatus arched upwards and the posterior wall backwards in such a way that there is a much larger passage in the osseous than in the cartilaginous meatus, and by detaching the cartilaginous meatus this larger space can be reached.

He also explained the anatomical reason which led Voltolini to recommend that in syringing out an ear to remove a foreign body the patient should lie on a table with the head hanging far backwards over the end. The angle formed by the membrana tympani with the lower wall of the meatus is very acute, and the arching of the lower wall upwards produces quite a deep cavity, into which foreign bodies not infrequently fall, and from which they may not be removed by the syringe. As the angle of the membrana tympani with the upper and posterior wall of the meatus is, however, very obtuse, Voltolini's idea is to reverse the head, making the upper wall for the time the floor of the meatus, and thus syringing the foreign body out down, instead of up, an inclined plane.

THOMAS'S ORTHOPEDIC SPLINTS.

DR. POST showed the splint and apparatus devised and used by Mr. Thomas, of Liverpool, for disease of the spine and joints. In the case of hip disease he disregards entirely extension, on which so much stress is

laid by American orthopaedists, and aims at what he calls "immovable fixation." His is not the only splint devised on this principle, but is simpler and cheaper than any other, and has hence a wider applicability.

DR. BRADFORD remarked that Mr. Thomas's book and methods deserve more attention than they have received in this country, and said that Dr. Post had been kind enough to apply the apparatus for him in a few cases. He thought that Thomas goes too far in neglecting extension entirely, but he enforces absolute rest for the joint, and attains it in his hip splint much more nearly than is customary here. A patient of his has now been wearing a Thomas's spinal apparatus for five or six weeks with marked benefit, but he has not as yet had an opportunity of testing the elbow and ankle splints. The cheapness of all these forms of apparatus is a great recommendation in hospital practice.

DR. COWLES read a paper on

NON-RESTRAINT IN ENGLISH AND SCOTCH ASYLUMS,

having visited a number of them during a recent trip to the other side of the water. The paper was reserved.

DR. FISHER said that he has watched this question closely for a number of years, and has known that such devices as iron window frames and seclusion have been resorted to in order to reconcile the safety of the patients and the popular feeling; which has, indeed, done great good. There are now signs of reaction in favor of restraint, which, it is to be hoped, will not go too far. The American superintendents have had the secret sympathy of their English brethren, and during a visit to Europe in 1867 he saw very little, either from a scientific or humane point of view, ahead of our own establishments. — DR. JELLY thought that every superintendent should make it a study to reduce mechanical restraint to a minimum; but it must sometimes be used, even four attendants not being sufficient to take care of severe cases. Our summer heat is so intense that many patients will prefer bars over the windows and the privilege of having the latter wide open at pleasure. — DR. BOWDITCH thought that the view was too commonly held that an insane person must necessarily be sent to an asylum; that very act will sometimes render a person permanently insane. — DR. LE BARON RUSSELL, present as a guest, said that an experience of fifteen years as trustee of the Taunton Asylum has convinced him that in many cases restraint is not only necessary, but humane. Repression by attendants is more irritating and seclusion is really a much more severe treatment than slight restraint. In one ward at Taunton the doors have been kept open lately, and the patients allowed to go freely out and in; of course, picked cases only are put into this ward. It is undoubtedly true that some cases of insanity can be best treated at home; but as a rule it is better to separate a patient from the circumstances and surroundings in which he became insane, and a hospital is the best place. In some chronic cases patients improve up to a certain point in hospital, and may then be sent home for a time as an experiment. We should have a larger number of attendants in our asylums, and these attendants should have more personal care for the patients, and endeavor to induce them to employ themselves as far as possible. — DR. J. B. AYER said that he has repeatedly seen patients who were continually struggling with attendants become calm very soon after the application of mechanical restraint, against which they felt the use-

lessness of struggles. — DR. WHITTEMORE thought that if physicians in general had a more intimate knowledge of insanity many patients who are now sent to asylums could be as well or better looked after at home. But it is often an expensive and inconvenient thing, as the private house must be turned largely into a hospital. — DR. JELLY said that he is in the habit of advising home treatment at first, when there is no great violence and no delusion or excitement about home.

FOREIGN BODY IN THE URETHRA.

MARCH 1, 1880. — DR. J. J. PUTNAM reported the case of a man who had come to his office that day. To overcome a supposed obstruction of the urethra he had introduced a long shawl-pin with a rounded glass head, and was unable to get it out again. The point of the pin protruded through the mucous membrane near the attachment of the frænum, and extraction was successfully performed by traction on the point until the head had nearly reached the meatus; the head was then turned out of the meatus, seized, and the pin removed. It measured six and one half inches in length. A catheter was then passed into the bladder with perfect ease.

CHRONIC INTERSTITIAL NEPHRITIS.

DR. M. H. RICHARDSON reported the case. A man of fifty-five was under the care of Dr. Bowditch three years ago, with albumen and casts in his urine and fluid in his left pleural cavity, for which latter he was tapped. Later he came under the care of Dr. Richardson, who found the urine slightly albuminous with a few granular and hyaline casts, and an hypertrophied and irregular heart. A diagnosis of contracted kidney was made. About a year later he began to have convulsions resembling those of epilepsy, recurring at intervals.

December 11th he passed 1820 cc. of urine, containing 29 grammes of urea; on the evening of that day he had a severe convulsion, followed by unconsciousness for several hours. December 12th, passed 900 cc. urine, containing 16.65 grammes of urea. December 14th, the urea amounted to 23 grammes; December 15th, to 14.65 grammes, and on the latter day he had another convulsion. After this he remained unconscious till death, the urine being drawn by catheter. December 18th he died, the quantity of urine secreted during the last twenty-four hours of life being 150 cc., containing 3.50 grammes of urea. While he was unconscious nitrate of pilocarpine, at first one sixth of a grain, later, one fourth of a grain, was injected subcutaneously; 230 cc. of saliva were collected in twenty minutes, containing 1.38 grammes of urea. After a subsequent injection 450 cc. of saliva were collected, containing 2.7 grammes of urea. An autopsy confirmed the diagnosis.

DR. J. J. PUTNAM read a paper on

A SERIES OF CASES CHARACTERIZED BY NUMBNESS OF THE HANDS,

which was reserved for publication.

DR. ELLIS expressed his interest in the paper, and said that patients with symptoms similar to those described by Dr. Putnam are often much alarmed by them, fearing paralysis, apoplexy, and the like, and it is very important to be able to reassure them. He found a lady waiting in his office one Sunday, weeping over her impending dissolution. She had been reading

a book in which similar symptoms were described, and forthwith found that she had them herself. — DR. FISHER remarked that in some of Dr. Putnam's cases the peculiar sensations came on early in the morning, a time at which suicide is very apt to occur, perhaps from diminished activity of the cerebral circulation.

AGORAPHOBIA.

DR. FISHER reported the case. A man of thirty is the picture of health, and in active business. He has been married eight or ten years; was formerly more or less intemperate, and once, while fishing and drinking freely in hot weather, had a transitory attack like sunstroke. For the last six years has been steady in his habits and unremitting in devotion to business, but has suffered somewhat from uncomfortable sensations in his head. About six months ago a feeling of insecurity in the region of the heart began to come on, and now attacks him whenever he attempts to walk alone, go into a church or theatre, ride in a horse-car, etc., and renders it impossible for him to do so. He drives down town in a buggy, is entirely well at home and at his office, and can transact business perfectly. This symptom is not infrequently associated with others, but alone is rare. — DR. PUTNAM remarked that the condition described by Dr. Fisher is analogous to the slight feeling of respiratory distress which ushers in a hydrophobic paroxysm, and is increased by apprehension and emotion.

THE PRINCIPLE OF THE SITHON APPLIED TO THORACENTESIS.

MARCH 15, 1880. DR. GARLAND reported two cases of pleurisy in the hospital service of Dr. Ellis, and discussed the feasibility of removing such fluid by drainage instead of by pump. His apparatus consists simply of a No. 3 Dieulafoy needle attached to a rubber tube one metre long and four mm. in diameter, with a bit of glass tubing inserted near the needle to serve as a window. With this instrument Dr. Ellis removed from one patient one hundred and thirteen ounces in sixty-five minutes, from another about fifty ounces in forty minutes. The flow was so gradual and uniform in both cases that the patients expressed no pain or discomfort. It has long been known that the negative force of the lung, at its best, is equivalent to a column of water thirty-nine cm. high; but when the retractility of the lung is diminished by reason of pleurisy it can no longer support such a column, and therefore if we employ a column of water sixty to one hundred cm. high it is evident that we can readily expand the lung.

The advantages which Dr. Garland claimed for this method were the ease with which it is performed, the comfort of the operator, who, having plunged in the needle, has nothing to do but to watch the flow, and the safety of the patient by reason of the slow and uniform aspiration. A good deal has been said of late about the danger of drawing off too much fluid at one sitting, but Dr. Garland thinks the chief danger lies in drawing it off too rapidly. Girgenson and others recommend this method of tapping, and report favorable results, but Girgenson employs a large canula, and thus empties the chest rapidly. Dr. Garland wished, on the other hand, to emphasize particularly the necessity of operating slowly.

After the insertion of the needle and before the fluid began to discharge from the chest, Dr. Garland con-

needed the drainage tube by means of a T branch with a mercury manometer. Then by opening the valve to the manometer he was able to read the amount of hydrostatic pressure in the chest. In Case I, the pressure was positive and equal to twelve mm. of mercury; that is, the tension of the effusion was sufficient to support a column of mercury twelve mm. high. In Case II, it was also positive, but equaled only two mm. of mercury. After removing fifty ounces from Case II, the pressure became decidedly negative, and fluctuated between eight and sixteen mm. This question of the tension of endopleural effusions has been tested by a number of observers, with results similar to the above. Homolle says the pressure is almost always positive at first, and becomes negative as the fluid passes out. If this diminution in pressure be gradual and uniform it is a favorable sign, but if it be sudden and abrupt it is very unfavorable; a low terminal pressure is also a bad symptom. The manometer may be of great service in distinguishing between effusions above and below the diaphragm, — a diagnosis which is sometimes difficult, as in a case reported by Pfuhl. When a collection of fluid is seated below the diaphragm it is evident that the descent of that muscle in inspiration will produce a positive pressure on the manometer. If, on the other hand, the fluid be above the diaphragm inspiration will produce a negative record.

Dr. Garland then discussed the deformity of the chest met with in large effusions. In Case I, the sternum was swung pediculum-like toward the affected side, so that the farther border of the bone occupied the normal position of the median line. Peyrot has found that this is the rule. He placed needles along the sternum, erected plumb lines at the head and feet of a corpse, and then injected one side of the chest with fluid. The sternum was carried toward the affected side in such a manner that the lower part of the bone traversed 4.5 cm. and the upper part two cm. This was concurrent with a marked bulging of the cartilaginous portions of the ribs on the affected, and flattening of the same on the opposite, side.

Dr. ELLIS testified that this siphon method works very smoothly and beautifully; it takes more time, but slow and gradual removal is what is required. The patients had no uncomfortable symptom whatever. — Dr. KNIGHT heartily indorsed the views of Drs. Ellis and Garland as to the desirability of slow removal. One class of serious, even fatal, accidents incident to thoracentesis can thus be avoided.

EMPYEMA.

Dr. J. G. BLAKE expressed his regret that he had not been present to hear Dr. A. T. Cabot's paper on empyema. He had lately operated on a case strictly according to Lister's method, but the pus reaccumulated, and contained so many clots that he was compelled to return to the old method.

Dr. A. T. CABOT suggested that perhaps the opening was not large enough; the chest may be washed out under spray every time the dressing is changed if it be deemed advisable. Since reading his paper he has operated on one case. About ten ounces of pus, smelling of sulphureted hydrogen, were discharged, and in ten days the patient was attending to his business in Boston, while living in Longwood, three miles off. The tubes were removed at the end of four weeks, and the opening healed during the three days following. Clots came away as late as the fourth dressing. — Dr.

KNIGHT expressed the opinion that the chest should be, once at least, thoroughly washed out. That this is not Lister's practice does not condemn antisepticism. — Dr. T. B. CURTIS remarked that Lister spoke of his method as rather difficult to carry out fully; the dressings must be changed daily, and many layers of gauze must be used. — Dr. A. T. CABOT said that it was well to make sure that the dressing is applied in such a way as not to obstruct the flow out from the drainage tube, and thus avoid coagulation as far as possible.

Recent Literature.

Ceremonial Institutions: Being Part IV. of the Principles of Sociology (the first portion of Vol. II). By HERBERT SPENCER. New York: D. Appleton & Co. 1880.

This little volume forms, as we learn from the title-page, the first portion of the second volume of the *Principles of Sociology* in Herbert Spencer's *System of Synthetic Philosophy*.

The author has decided to issue by itself this and each succeeding division of Vol. II. of the *Principles of Sociology*, for several reasons. Each division, though related to the rest, nevertheless forms a whole so far distinct that it may be fairly well understood without the rest. Volume second threatens to be even more bulky than volume first, and the author rightly thinks these large volumes are more alarming and less apt to be read than small, separate parts. Moreover, he wishes to avoid the delay otherwise inseparable from the completion of an entire volume. He has undoubtedly judged wisely.

This Part makes a very convenient, substantially independent little book, in which *Ceremonial Institutions* are discussed in twelve chapters, and traced from their earliest development in savage tribes to their comparative neglect in countries like England and the United States, where liberty and law go hand in hand. The manner of handling the subject is interesting as well as instructive, and in this form these chapters will be read and appreciated by many who would not have had the courage or the good fortune to get at them in a ponderous tome with an abstruse philosophical title. The references are collected at the end of the volume in a compact form, and give some idea of the laborious research compressed into the few pages between these covers. For its moderate price the book is well gotten up, but the type is not always as distinct as it might be, and on page 210 we notice such a mistake as the following: "And by so doing has aided in weakening Ceremonial, which implies subordinates the individual."

American Health Primers: Our Homes. By HENRY HARTSHORNE, A. M., M. D., formerly Professor of Hygiene in the University of Pennsylvania. Philadelphia: Presley Blakiston. 1880.

Our Homes is the ninth in the series of *American Health Primers* edited by Dr. W. W. Keen. It is written by Dr. Hartshorne, formerly professor of hygiene in the University of Pennsylvania, and contains many useful hints on the situation, construction, light, warmth, ventilation, water supply, drainage, and disinfection of houses; also a short chapter on population, and a few separate pages devoted to workingmen's homes.

Medical and Surgical Journal.

THURSDAY, APRIL 15, 1880.

A Journal of Medicine, Surgery, and Allied Sciences, published weekly by HOUGHTON, OSGOOD AND COMPANY, Boston. Price, 15 cents a number: \$5.00 a year, including postage.

All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.

Remittances by mail should be sent by money-order, draft, or registered letter to HOUGHTON, OSGOOD AND COMPANY, Boston, Mass.

FURTHER PROGRESS IN MEDICAL EDUCATION.

We are happy to be able to announce that the "boom" in education in this country is not over yet; that there still appears to be a very considerable amount of vitality in the movement, if we may judge from the announcement given below. The new plan at Harvard has had several years of trial, and has proved, as is now well known, a most gratifying success. Students have been quick to find out the great advantages of a thorough and systematic preliminary training, without which a medical education is but a house built upon the sand. The foundation having been provided for, it now remained to complete that system of personal instruction in various special departments which has proved so successful in some of the large medical centres, as Vienna. It soon became evident that although the sessions lasted a full academic year the time was altogether inadequate to carry out the numerous courses of instruction. The faculty has therefore decided to prepare a plan which shall extend over four full years, and to offer it to all comers who feel disposed to take it; for those who do not there will still remain the old three years' course, which has been changed in no respect. This step marks, we believe, a very important era in the history of medical education in this country; the experiment will be watched with great interest by professional men throughout the land. Had a majority of the faculty felt authorized to take a bolder step, and make the new course of instruction obligatory upon all, we believe that their action would have been justified by the result. As it is there is room for much congratulation that we are to be permitted to see whether so valuable a plant will flourish on American soil with sufficient vigor to bring forth fruit. We have ourselves no doubt that the soil is sufficiently fertile, and only awaits the opportunity to show its powers.

The following is the announcement of the course of study which is to take effect in and after the next academic year, 1880-81.

The course of study recommended by the faculty covers four years, the examinations being distributed as follows:—

First year. Anatomy (3 hours); Physiology (3 hours); General Chemistry (3 hours).

Second year. Topographical Anatomy (1½ hours); Pathological Anatomy (3 hours); Medical Chemistry (3 hours); Materia Medica (3 hours).

Third year. Therapeutics (3 hours); Theory and Practice (3 hours); Obstetrics (2 hours); Surgery and Surgical Pathology (3 hours).

Fourth year. Clinical Medicine (3 hours); Clinical and Operative Surgery (2 hours); Ophthalmology and Otology (1½ hours); Dermatology and Syphilis (1½ hours); Mental and

Nervous Diseases (1½ hours); Laryngology (½ hour); Hygiene and Legal Medicine (1 hour); Obstetrics, Clinical and Operative (2 hours); Diseases of Women (1 hour); Diseases of Children (1 hour).

But until further notice the degree of Doctor of Medicine will continue to be given upon the completion of three years of study, to be as ample and full as heretofore, to candidates who have passed satisfactorily the following series of examinations:—

First year. Anatomy (3 hours); Physiology (3 hours); General Chemistry (3 hours).

Second year. Topographical Anatomy (1½ hours); Pathological Anatomy (3 hours); Medical Chemistry (3 hours); Materia Medica (3 hours).

Third year. Therapeutics (3 hours); Theory and Practice (3 hours); Surgery and Clinical Surgery (3 hours); Obstetrics (3 hours); Clinical Medicine (3 hours).

The degree of Doctor of Medicine *cum laude* will be given to candidates who have pursued a complete four years' course, and obtained an average of seventy-five per cent. upon all the examinations above stated. In addition to the ordinary degree of Doctor of Medicine as heretofore obtained, a certificate of attendance on the studies of the fourth year shall be given to such students desiring it as shall have attended the course, and have passed a satisfactory examination in the studies of the same.

The preliminary examination has also been recast, and in its present form is a much more satisfactory one, both to students and teachers. Some portions of it have been strengthened,—the examination in English is now a reality,—while, on the other hand, it has been found advisable to adopt a standard of Latin more in accord with the requirements of the high schools, but the language is now exacted from all applicants. To the elective requirements are added algebra, geometry, and botany, as will be seen below:—

(1.) *English.* Every candidate shall be required to write, legibly and correctly, an English composition of not less than two hundred words, and also to write English prose from dictation.

(2.) *Latin.* The translation of easy Latin prose.

(3.) *Physics.* A competent knowledge of physics (such as may be obtained from Balfour Stewart's Elements of Physics).

(4.) *Elective Subject.* Each candidate shall pass an approved examination in such one of the following branches as he may elect: French, German, the Elements of Algebra or of Plane Geometry, Botany.

There is nothing in this course of study which should prevent the student of average means and ability from undertaking it. We must remember that this is the minimum exacted in European countries, where the emoluments or the chances of success are certainly not greater, if so great, as in this.

Its great advantages consist in the careful mental training enjoined upon the students, who thus acquire knowledge that cannot be obtained in after-life. The lectures of a brilliant teacher or the opportunities of celebrated clinics, according to our American system, are supposed to be the great recommendations of a school; but these are no substitute for the self-exertion and hard drill which the new system entails, an ordeal which no one will submit to after he has obtained his degree, and which alone can enable him to study disease at the bedside with profit.

SALE OF DIPLOMAS BY FRAUDULENT CORPORATIONS.

We have received from the Bureau of Education of the Department of the Interior in Washington a circular requesting information in regard to the sale of diplomas issued by fraudulent corporations in this country to subjects of foreign powers, and suggestions

for the suppression of this disgraceful traffic. In the letter from Philadelphia in our issue for March 18th, and again in a communication in the issue for April 1st, the extent and iniquity of this practice are quite fully described.

The offenders, or some of them, have been several times exposed, but these individuals, especially in Philadelphia, seem to be as irrepressible as the illicit distillers in the mountains of North Carolina.

For a number of years great complaint has been made in France, in Belgium, and in England of this traffic in spurious diplomas, and now complaints have reached the State Department at Washington through our minister in Berlin.

It is a thing which affects our good name, and there should be some way found by which this sort of knavery can be put a stop to.

Something more may reasonably be expected of us than a shrug of the shoulders, and the reply that foreigners cannot ask us to do for them what we don't do for ourselves.

We hope shortly to return to the subject again; in the mean time we should be glad to publish any remarks or suggestions which any of our readers may have to offer. It takes a good many such steps as Harvard University is just making toward a higher medical education to counteract the evil effects of these swindles engrossed on parchment.

THE SUPPLEMENTARY REPORT OF THE HEALTH DEPARTMENT OF THE BOARD OF HEALTH, LUNACY, AND CHARITY.

It will be remembered that only eight pages of the First Annual Report of the new complex Massachusetts Board of Health, Lunacy, and Charity were devoted to the consideration of matters pertaining to health; these constitute Part First of that Report, and cover a period of only three months. The papers and special reports relating to the public health were promised in a supplement. An appropriation has now been made for the printing of this Supplementary Report, and it has been resolved by the legislature that 4600 copies be printed and distributed as follows: 1600 copies for the use of the health department of the board; five copies to each member of the legislature, etc., etc.; and that there shall be held on sale, by the secretary of the commonwealth, 1000 copies at a price not less than their actual cost. Some of the papers to be published in this supplement are on especially interesting and important subjects.

CONTRACT SURGEONS.

In the recent discussion of the army appropriation bill before the House of Representatives, the medical department came in for its full share of debate, and the question seemed to turn principally upon the employment of contract surgeons, the impression prevailing with some that these were unnecessary, superfluous,

and expensive. In consequence, no doubt, of the nature of the matter under consideration, namely, the bloody combination of war and surgery as exemplified in the contract surgeon, one of the members became very warlike and defiant, but, as is usual, made parliamentary explanations, and thus quieted his conscience. The amendment to the bill, which embodied the matter under discussion, as finally modified and voted down, was as follows:—

“Contract surgeons shall not be employed until all commissioned surgeons shall have been assigned to duty with troops, and then only upon request of the commanding officer, approved by the general of the army; but this shall not be construed to require assignment to duty with troops of commissioned surgeons who are now, or may hereafter be, put in charge of the national soldiers' home, or those who are detailed to prepare the Medical and Surgical History of the War of the Rebellion, or those who may be detailed upon examining boards.”

It appears from the debate that there are one hundred and nineteen contract surgeons, and it was held that if all the commissioned medical officers eligible for duty were assigned to their posts the necessity for these contract surgeons would cease; or, if not, the corps of commissioned medical officers should be increased. The letter of Surgeon-General Barnes, as read, shows that the contract surgeon is in demand for temporary duties because the present medical force is insufficient, and because such contracts are economical and advantageous to the government, these contracts ceasing the moment that the services of the surgeon are no longer required. The letter further showed that the number of military posts, so dwelt upon in the debate, was no criterion for the number of medical officers required by the service, as a number of these contract surgeons were in demand for scouting parties.

In one of the arguments some of these contract surgeons were characterized as men who could not get into the army through the regular examination, and thus, by inference, the rest were implicated. This is indeed severe criticism if it is to be applied to men, many of whom undoubtedly have the choice between the life of a civil practitioner and that of an army surgeon, and have chosen the former, but who avail themselves of the opportunity to increase their income by taking a contract. The gentleman using this argument, in further commenting on the incompetence of some contract surgeons, as proven by the views solely of their for the time enforced patients, was probably not aware of the idiosyncrasy common with so many patients, both in and out of the army, of never being satisfied with the medical skill provided for them when independent of their own free selection.

Mr. Hawley, of Connecticut, paid a handsome compliment to Surgeon-General Barnes, and brought out the fact that neither to him nor to Assistant Surgeon-General Crane had the courtesy been extended of inviting them before the committee to explain their views. It seems to be a very small matter, and in-

judiciously urged, to attempt to trammel the surgeon-general of the United States army in his selection of contract surgeons to meet emergencies; and it certainly cannot be on the score of economy, for, if the statements in debate are correct, their pay is much less than that of any commissioned medical officer.

A curious amendment has been proposed, consequent upon this debate, which is in effect that an acting assistant surgeon, after five years of continuous service, shall have a month's leave of absence for each year of that service, with pay; shall then attend a course of lectures at some medical college, be allowed to present himself for examination, and, if passed, be commissioned as an assistant surgeon.

MEDICAL NOTES.

—The *Medical Press and Circular* says that those timid beings who are haunted by apprehensions of being buried alive, and who make testamentary provisions against such a contingency, may now take courage, for science has supplied an infallible means of determining whether or not the vital spark has quitted the mortal frame. Electricity enables us to distinguish with absolute certainty between life and death; for two or three hours after the stoppage of the heart the whole of the muscles of the body have completely lost their electric excitability. When stimulated by electricity they no longer contract. If, then, when faradism is applied to the muscles of the limbs and trunk, say five or six hours after supposed death, there be no contractile response, it may be certified with certainty that death has taken place; for no faint, nor trance, nor coma, however deep, can prevent the manifestation of electric muscular contractility. Here there is no possibility of mistake, as there certainly was when the old tests were employed. Muscular contractility under the faradic stimulus disappears gradually after death. It is instantly diminished, but only finally extinguished in about three hours; and hence Dr. Hughes Bennett has suggested that electricity may sometimes be of use in medico-legal investigations by affording evidence as to the time of death.

—Dr. A. A. Smith recently exhibited to the New York Clinical Society a glass pessary, which had been given him by a medical friend living out of New York, with the following history: In 1849—thirty years ago—it was introduced into a vagina, and had not been once removed until a short time ago. The woman recently fell down-stairs, and subsequently had a bloody vaginal discharge. The physician discovered and removed the pessary, which had become well imbedded in the tissues. It was incrustated with calcareous deposit, and was introduced for uterine displacement years ago, with no advice, according to the woman's statement, regarding its subsequent removal. The pessary was concavo-convex, and about three inches in diameter, with a small opening in its centre. To effect its removal, a catheter was passed through this opening and traction made upon it. Dr. Smith called

attention to the duty of physicians to impress upon patients the importance of the regular removal of pessaries. Dr. Peabody said he had found a pessary, thickly coated with calcareous material, in making a post-mortem examination. He mentioned an instance of the removal of a pessary, by Dr. E. K. Henshel, which had been introduced seventeen years before by the latter's father. Dr. Foster said he had cut out from the vaginal tissues a pessary which seemed to have been made of iron. Dr. Smith mentioned the removal of one by Dr. Sayre from the uterine cavity after its retention for ten years, and alluded to another case of prolonged retention of a pessary in the vagina, which finally gave rise to an attack of peritonitis. Dr. Weir remarked that he had removed a glass pessary eight years after its introduction, and asked whether glass pessaries were better borne than others, to which there was no reply.

—Opinions concerning the value of condensed milk as a food for infants seem to be strikingly various. The fact that one physician writes that condensed milk is injurious to children, while another asserts that no form of milk is either so reliable or so nourishing, indicates a difference in judgment so curious that we should be glad to collect opinions touching this matter. If physicians who have used this food will address to the *Boston Medical and Surgical Journal*, 47 Franklin Street, Boston, Mass., their views respecting its usefulness and effect, as compared with those of such milk as is ordinarily supplied by milkmen, we will make and in due time publish a *résumé* of the same.

—Of the audiphone the *Chicago Medical Journal and Examiner* says, "Messrs. Sharp & Sons have been carefully testing this instrument for several weeks, but thus far have not found any patients benefited by it. Out of one hundred and fifty successive cases they report that not one has noticed any benefit in its use.

—The notorious liver-pad (Holman's) is composed of drilling, and filled so as to be about one half an inch or more in thickness. The contents are ground fenugreek seed and ground flaxseed fifty per cent.; pitch, resin of galbannum, and resin of sandrac forty-five per cent. The remainder is supposed to be composed of aromatics. The fenugreek gives the peculiar odor, though this is modified by the resin and aromatics.

—The *Medical Press and Circular* makes the following comments on Dr. Wood's opinion of the professional status in England:—

"In a recent number of the *Philadelphia Medical Times*, a leading article is devoted to considering why the status of the medical man in England is lower than that of his brother across the Atlantic. The conclusion arrived at is that medicine will never be able to compare favorably with the other learned professions until it is placed on a basis similar to them; that is, 'until there are medical lords who have a right to speak upon the floor of the House of Lords, and who shall exert an influence on the decision of all questions of state medicine, comparable to that of the law lord in legal questions.' Only then, concludes the *Times*,

can the medical profession of Great Britain 'expect to control the governmental action as they do in America, or be recognized by the mass of Englishmen as entirely the peers of members of the other professions.' Whatever truth there may be in these remarks, we are ourselves of opinion that the adventitious aid of handles affixed to the names of a few will not materially advance the general professional dignity. One of the most powerful engines in this direction would be a union among medical men, by which common aims would be advanced and the elevation of the whole class be secured. To the want of cohesion among the members of our profession, and the absence of any centralization agency, is due much of its inherited weakness."

—The *Medical Press and Circular* publishes this interesting item: The inexhaustible usefulness of glycerine has received another illustration by the erection at the Kew Observatory of a glycerine barometer, the invention of Mr. Jas. B. Jordan, of the *Mining Record* office, where it is to be rigidly tested. The advantage it possesses over mercury is that its indications of minute atmospheric variations are more easily observable, and it is thought that for meteorological stations, collieries, and some other such institutions, this facility would be of advantage. Glycerine varies an inch where mercury only varies one tenth of an inch; but the mean height of its column against the air pressure is twenty-seven feet. A difficulty in the use of glycerine occurred in the fact that the exposed surface freely absorbed moisture, but this has been overcome by covering the surface exposed in the cistern of the barometer with a layer of heavy petroleum oil prepared specially for the purpose. The barometer fixed at Kew has its cistern in a room below that where the observations are taken, so as to obtain the necessary length of column. About three fourths of a gallon of glycerine, colored red by aniline, were required to fill it.

—When a death occurs in Fiji it has to be registered; and the native scribes not unfrequently fill the blank left for "cause of death" with the words, "medicines supplied by the missionaries."

—Scarlatina of fatal form prevails in St. Johnsbury, Vt., and vicinity. Three patients, one adult and two children, have died in the same week. This family resided over a meat market. The winter has been warm, the meat room damp, the drainage imperfect; the house is old; the rooms are low, badly ventilated, and worse lighted. In other tenements in the immediate neighborhood have followed other fatal cases. Typhoid fever and diphtheria of severe type prevail in the towns near the White Mountains.

—J. Matthews Duncan and Dr. Pirrie, of Dundee, each report a case of spontaneous dilatation of the virgin uterus with profuse hamorrhage.

PHILADELPHIA.

—At a meeting of the Board of Trustees of the Jefferson Medical College, held on the 12th inst., Dr. Henry C. Chapman, of Philadelphia, was elected to fill the chair of Institutes of Medicine and Medical

Jurisprudence, made vacant by the death of Professor Meigs. Dr. Chapman had, by appointment of the trustees, filled the unexpired term last winter; taking up the course at very short notice, and carrying it on without any delay or interruption, and with great satisfaction to the class. The appointment is considered a good one; and, in view of the distinguished positions of several who are named as his competitors for the prize, it is a very high compliment to Professor Chapman, though certainly not undeserved.

WASHINGTON.

—The United States Congress, during the past few days, has had several matters of medical interest for discussion. The resolution before the Senate for printing 10,000 copies of the Medical and Surgical History of the War of the Rebellion was indefinitely postponed in consequence of a letter from Surgeon-General Barnes, in which he states that the passage of the resolution would very seriously and injuriously retard the completion of the remaining two volumes, which are now in press, as the artists engaged upon the illustrations would have to suspend their present work to reproduce the illustrations for the four volumes already published. He further states that if the original edition of 5000 had not been increased to 10,000 after the first two volumes had been published, the whole work would have been completed before now, and its distribution have been more uniform. From this letter it seems to have been the intention of the surgeon-general to make a distinction between practitioners of medicine and surgeons in civil life, and to distribute the medical and surgical volumes in accordance with that distinction; sending the whole set alone to libraries, colleges, or the most eminent authors and teachers in the profession, from the fact that, when completed, the work would be made a basis of systems of military medicine and surgery, and thus be reproduced in a less costly form.

—On April 8th, there were presented to the House of Representatives the resolutions of the city of Savannah, Georgia, which declare the proposed conferring of increased powers upon the National Board of Health to be revolutionary in its tendencies and contrary to the spirit of our institutions.

DISSECLAMP.

THE MEDICAL LAW OF NORTH CAROLINA.

MR. EDITOR, — The discussions published in your JOURNAL in relation to the proposed law for regulating the practice of medicine in Massachusetts have so interested me that I am disposed to believe your readers may be correspondingly interested in a short account of the provisions and effect of such a law in my State.

Our board of medical examiners is composed of seven members, elected from the state medical society, and holding office for six years. After due examination they are empowered to grant, refuse, and even revoke a license to practice medicine or surgery in any or all of its branches. To practice without a license from this board is not a misdemeanor which can be

punished, but the practitioner without such license is effectually debarred from collecting by law any fee or reward for his professional services.

This law has now been in operation for twenty-one years. A glance at the accompanying copy of it will show you its tenor and scope. (If any of your readers desire a copy I will gladly supply them.) Despite its imperfections it has done incalculable good throughout the State in elevating the tone and character and standing of our profession, in fostering a higher standard of professional as well as general education, and in defining the line between regulars and irregulars. The public appreciates and supports the effort of the medical society and the board of medical examiners to give and maintain to the medical profession its deserved status and influence. By informing the people through the newspapers of the object and requirements of our board of medical examiners we bring a pressure to bear upon many who would otherwise be beyond our reach. They are forced either to apply for license or acknowledge their incompetency. (Inclosed is a copy of the notice we are sending out this year.)

NOTICE.

"The undersigned, a committee appointed for the purpose by the Medical Society of North Carolina, respectfully ask you to publish the following notice for the information of your subscribers.

"The Board of Medical Examiners of the State of North Carolina will meet in the city of Wilmington on Monday, May 10, 1880, to examine applicants for license.

"Without a license from this board 'no person shall practice medicine or surgery, or any of the branches thereof, or in any case prescribe for the cure of disease for fee or reward;' and, furthermore,

"He 'shall not be entitled to sue for or recover, before any magistrate or court in this State, any medical bill for services rendered in the practice of medicine or surgery, or any of the branches thereof.' (Laws of North Carolina, 1858-59.)

"PETER E. HINES, M. D.,
W. T. ENNETT, M. D.,
H. T. BARNSON, M. D. } Committee."

Last year we examined forty-one applicants. Of these, thirty-six were granted licenses, and to five they were refused. Four of the latter were graduates. It is our purpose to tabulate and publish the result of our examinations at the end of our term of service. It will perhaps aid in determining the character of examinations required by some of our American medical schools. Wishing my brethren in Massachusetts the success their efforts deserve, I am yours truly,

HENRY T. BARNSON,

Secretary Board of Medical Examiners of North Carolina.

SALEM, N. C., April 5, 1880.

THE DEATH OF WASHINGTON.

At a recent meeting of the Literary Society of Washington, the evening was devoted to an exhibition of relics of George Washington, and to a discussion of his life and history. Dr. J. M. Toner alluded to reminiscences of Washington, and finally remarked that before taking his seat he would say one word upon

the disease of which General Washington died and the medical treatment he received. This subject has frequently been discussed, and recently revived by one of our own papers. The physicians, Drs. James Craik, Elisha Dick, and Gustavus Brown, who attended General Washington, appreciating the propriety of giving some account of the character of his illness and death, published over their own signatures a circumstantial account of it in the first issue of the *Alexandria Times* after the melancholy event. Colonel Lear, the general's private secretary, within twenty-four hours after his decease wrote out an account of the disease. By reviewers and writers on this subject there has been much cheap criticism and sentimental declaration. But few have taken the trouble to ascertain all the facts, or, having the facts, have not had the medical knowledge to give them their due weight. To Edward Everett we are indebted for having had a thorough and comprehensive study of The Last Sickness of General Washington and its Treatment by the Attending Physicians, made by Dr. James Jackson, of Boston, confessedly at the head of his profession in America, and from whom we derive the following facts: The disease was acute laryngitis, and the severity of the attack allowed but brief time for medical treatment. It is a rare disease, and in its violent form almost uncontrollable; inflammation of the larynx (the upper part of the windpipe). The disease at the time of Washington's death had not been so clearly described as to distinguish it from all other diseases of the throat. It was about 1810 that Dr. Matthew Baillie, of London, one of the first physicians of that metropolis, published an account of two cases seen by himself, both in medical men, one of whom was his personal friend. They proved fatal. A third case was reported to him. Of each of these careful post-mortem studies had been made. It was ascertained in these examinations, as it has frequently been since, that the disease consists of an inflammation of the mucous membrane and subjacent tissue and soft parts of the whole larynx, including the epiglottis. From the altered form of the glottis by the swelling, swallowing becomes difficult or impossible, and from the lessened capacity of the larynx or windpipe by the swelling which takes place on the inside the passage of air to the lungs is effectually excluded, and death ensues from suffocation. In the rapid course such cases run, debility plays but a small part. Suffocation ensues from the swelling and inflammation of the inner walls of the larynx, and as effectually destroys life as would strangulation from pressure by a cord or other force applied from without. Thus the sudden destruction of life is readily understood. The disease, it is allowed, was one of acute inflammation, and after eighty years of progress in the science of medicine this disease, while better understood, is still a formidable one, and in its severe forms generally fatal. Dr. Baillie, recognizing the inflammatory and dangerous character of the disease, bled his patients both generally and locally, and applied blisters and other remedies similar to those used by Dr. Craik. This occurred at a period sufficiently near that of the death of General Washington to contrast their treatment. What do the best teachers and practitioners of the present day direct in such cases? Keeping the case in point before us, we do not hesitate to say, in a general way, that in violent cases they would recommend bleeding and blistering. A surgical operation that would have opened the larynx might possi-

bly have given some relief, and possibly prolonged, if it had not preserved, his life. It is not deemed desirable to go farther into the subject, and we confess, from the knowledge we have of the character and professional abilities of Dr. Craik, that he not only fully comprehended the character and gravity of the disease of which his illustrious friend died, but that he treated it with judgment, and that he and his friends did as well under the circumstances as would have any of his critics.

HYSTERICIS.

In reference to the treatment of hysterics, Dr. William Goodell said not long ago, in a clinical lecture, "I think that this woman told me that she suffered from falling of the womb, but, however that may be, she is certainly a very nervous woman, almost hysterical,—so much so that she cannot answer any of my questions. I try to calm her by holding her hand firmly, and endeavor to divert her attention by feeling her pulse. You will sometimes find this a very excellent means of quieting these hysterical patients. Her hysterical aphonia is very marked, but I gather, from her sobbing utterances between the spasms, that she is thirty-four years of age, and unmarried. This hysterical contraction of one or all of the sphincters of the body is a very strange thing for us to understand, but we very often meet with it. Now it is a spasm of the sphincter ani, with difficulty in defecation; again, it turns up as dysuria, with scalding sensations in the passage of the urine, due to contraction of the muscular fibres throughout the whole length of the urethral track; or we may have spasm of the internal os uteri, or, as in this instance, of the epiglottis and trachea.

"I introduce my hand into the vagina, and find a virgin os, long, sickle-shaped, and looking upward and forward, instead of downward and backward. But the examination gives rise to so much pain and such hysterical symptoms that I shall postpone it until after the lecture is ended. Meanwhile, let me say a few words to you regarding hysteria and its treatment.

"Hysteria is a disease to which every woman is liable, and which every physician will be, some time or other, called upon to treat. Most of you will find it very hard, in most instances, to distinguish between hysteria and organic disease, for, in many instances, it mimics exactly grave structural diseases. There is no difficulty in forming a diagnosis when you meet with a real hysterical attack, attended with screaming and groaning and kicking.

"When you are called to treat a young girl with a hysterical attack, there are three things which you had better do: (1.) Institute at once firm pressure in the neighborhood of both ovaries. This is very apt to quiet the patient at once. (2.) Administer an emetic. I have found that a woman who is well under the action of an emetic has not the opportunity to do anything else than be thoroughly nauseated. Give a full dose of ipecac with one grain of tartar emetic. (3.) And this method of controlling the spasm will often act charmingly: take a good-sized lump of ice, and press it right down upon the nape of the neck. This produces quiet by its powerful impression upon the nervous system.

"When the attack is entirely under control, the best method of preventing the occurrence of another attack

is to administer a full dose of assafoetida,—none of your small two or three grain doses, but ten grains all at once.

"I am in the habit of regarding a hysterical woman in the same light as a skittish, unmanageable horse, and just as I catch the one by means of a handful of oats, so I do not hesitate to entrap the woman by much the same means. I remember one instance in which I assured the husband of a hysterical woman that the drug I was giving—assafoetida—had a very powerful odor, and had come from a very great distance. I have no doubt that he thought I had sent all the way to the Orient after it, and gave his wife to understand accordingly; certainly my words acted like a charm in that case.

"There is everything in a doctor's manner in the sick-room, and he who looks and speaks hopefully, saying, 'Take this, and you will get well, and do that, and you will feel better the next moment,' is much more likely to cure his patient than the man who magisterially goes through the motions without a ray of light or hope in his face, ordering, 'This pill to be taken in half an hour,' and, 'So many teaspoonfuls of that prescription to be given at such and such times.'

LIFE INSURANCE RUN MAD.

MR. EDITOR.—Last week a certain very smooth-tongued agent, highly perfumed and gorgeously attired, presented himself at my office, representing himself as an agent for a Golden Legion of Methuselah, or something of the sort, of which he was desirous of establishing a lodge or council in this place; and after eulogizing its advantages in glowing colors, and appealing to me most earnestly to allow myself to become a sort of grand supreme commodore and medical examiner for this locality, with the high and mighty title of P. Q. R. X., etc., etc., he handed me a circular containing further information and instructions. Having already listened to numerous appeals of a similar nature, I scrutinized the circular with care, and noticed the following facts: Medical examinations pass from the hands of the local medical examiners to the headquarters of the *grand high chief medical examiner*. On the fly-leaf of this circular I discover the fact that this same chief medical examiner is no other than a notorious quack, inventor, and dealer in a certain *patent catarrh pad*. The same person is also a dealer in the regalia and other trumpery so necessary to this sort of life insurance, and hence his efforts in the frequent establishment of new orders.

There is quackery in life insurance as well as in medicine, and when educated physicians are induced to submit the results of their examinations for revision to a patent-medicine quack it is time their eyes were opened.

An epidemic of *cheap* life insurance appears to be sweeping over the country; when the bubble bursts the old proverb will be fully illustrated: "*You cannot buy more than a shilling's worth of pork for a shilling.*"

ETHICS.

—Mr. Christopher Heath, of University College has been elected chairman of the Board of Examiners in Anatomy and Physiology at the Royal College of Surgeons of England.

REPORTED MORTALITY FOR THE WEEK ENDING APRIL 3, 1880.

Cities.	Population estimated for July, 1875.	Reported Deaths in each.	Deaths under Five Years.	Percentage of total Deaths from

Two thousand six hundred and ninety-four deaths were reported; 987 under five years of age: principal "zymotic" diseases (small-pox, measles, diphtheria and croup, diarrhoeal diseases, whooping-cough, erysipelas, and fevers) 442, consumption 415, lung diseases 387, diphtheria and croup 147, scarlet fever 60, measles 56, typhoid fever 54, diarrhoeal diseases 35, whooping-cough 31, malarial fevers 26, erysipelas 19, cerebro-spinal meningitis 13, small-pox one. From *measles*, New York and Brooklyn 13, Chicago 11, Philadelphia seven, St. Louis five, New Orleans, Buffalo, Pittsburgh, New Haven, Charleston, Lawrence and Holyoke one. From *whooping-cough*, St. Louis six, Chicago four, New York, Boston and Pittsburgh three, Philadelphia, Brooklyn, Cleveland, and New Haven two, New Orleans, Buffalo, Charleston, and Nashville one. From *malarial fevers*, New Orleans nine, St. Louis six, New York five, Brooklyn three, Baltimore two, Chicago one. From *erysipelas*, New York seven, Philadelphia four, Chicago two, Baltimore, Providence, Worcester, Lawrence, Chelsea, and Newburyport one. From *cerebro-spinal meningitis*, New York five, Chicago two, Boston, Cleveland, Pittsburgh, Worcester, Fall River, and Somerville one. From *small-pox*, Philadelphia one. Lung diseases and diphtheria were prevalent in Norfolk in March.

One hundred and fifty-seven cases of measles, 38 of diphtheria, 36 of scarlet fever, and one of typhoid fever were reported in Brooklyn; diphtheria 22, scarlet fever 10, in Boston; diphtheria 12, scarlet fever five, in Milwaukee; scarlet fever 14, diphtheria 12, cerebro-spinal meningitis two, typhoid fever two, erysipelas one, in Providence; diphtheria two, scarlet fever one, in Cambridge; scarlet fever five, diphtheria one, in New Bedford. Scarlet fever and diphtheria are declining in Cleveland; unusual prevalence and virulence of measles are reported in Brooklyn.

The total number of deaths reported was somewhat greater than for the previous week; of deaths under five about the same. Lung diseases showed a slightly increased mortality, pulmonary consumption decreased. Malarial fevers, scarlet fever, and

measles were more fatal; there was an excessive increase in typhoid fever, chiefly due to an epidemic in Pittsburgh; whooping-cough caused fewer deaths, and diphtheria remained without essential change. The death-rate of whites in Washington was only half that of colored. In 39 cities and towns of Massachusetts, with an estimated population of 1,045,760 (population of the State about 1,690,000), the total death-rate was 20.89 against 21.96 and 21.47 of the previous two weeks, with an increased mortality from typhoid fever.

For the week ending March 13th, in 145 German cities and towns, with an estimated population of 7,709,724, the death-rate was 26.9 against 28.2 and 27.1 of the previous two weeks. Three thousand three hundred and ninety deaths were reported; 1945 under five; pulmonary consumption 595, acute diseases of the respiratory organs 544, diphtheria and croup 138, scarlet fever 66, whooping-cough 57, measles and *rötheln* 55, typhoid fever 54, perneal fever 26, typhus fever (Pösen, Bronnberg, Brunschwiek, Berlin) 4, small-pox (Thorn and Dresden) two, trichinosis (Berlin) two. The death-rates ranged from 18.7 in Mannheim to 42.9 in Dortmund; Königsberg 25.7; Dantzig 27.5; Breslau 33.3; Munich 37.8; Dresden 22.2; Berlin 23.5; Leipzig 31.7; Hamburg 27.2; Hanover 21.9; Bremen 23.8; Cologne 27.5; Frankfurt 23.2. For the same week, Vienna 31.7, — small-pox and diphtheria very prevalent; Paris 31.7, — small-pox, measles, diphtheria, typhoid fever, and lung diseases very prevalent.

For the week ending March 20th, in the 20 English cities, with an estimated population of 7,499,468, the death-rate was 21.4 against 21.4 and 22.1 of the previous two weeks. Three thousand and seventy-five deaths were reported: acute diseases of the respiratory organs 315, whooping-cough 169, scarlet fever 113, measles 91, diarrhoea 39, fever 30, diphtheria 23, small-pox (London) 11. The death-rates ranged from 10.7 in Brighton to 34.8 in Oldham; London 20.9; Bristol 18.3; Birmingham 18.4; Liverpool 23.6; Manchester 28.3; Leeds 19.8. In Ed-

inburgh 27, Glasgow 24, Dublin (small-pox three deaths) 37. In the 20 chief Swiss towns, lung diseases and diarrhoea continued very prevalent; typhoid fever caused a large number of deaths in Zurich, and one each in Geneva, Berne, St. Gallen and Fribourg; diphtheria was less prevalent; scarlet fever caused two

deaths in Zurich and one in Berne: diphtheria was reported in Lausanne, Berne, Winterthen, and Schaffhausen. No deaths from small-pox.

The meteorological record for the week in Boston was as follows:—

LIST OF CHANGES IN THE MEDICAL CORPS OF THE NAVY DURING THE WEEK ENDING APRIL 10, 1880.

PASSED ASSISTANT SURGEON E. Z. DERR detached from the receiving ship at New York, and ordered to the naval hospital, Norfolk.

Assistant Surgeon H. G. BEYER detached from the Colorado on the 14th inst., and wait orders.

PASSED ASSISTANT SURGEON W. R. DUBOSE detached from the naval hospital, New York, and ordered to the receiving ship Colorado.

Assistant Surgeon F. S. NASH detached from the U. S. S. Lackawanna, and ordered to the receiving ship Colorado, New York.

PASSED ASSISTANT SURGEON A. C. HEFFINGER detached from the naval hospital, Chelsea, and ordered to the Lackawanna.

PASSED ASSISTANT SURGEON GEORGE P. BRADLEY ordered to the naval hospital, Chelsea, Mass.

PASSED ASSISTANT SURGEON C. W. DEANE ordered to the receiving ship Wabash, Boston, Mass.

PASSED ASSISTANT SURGEON A. A. AUSTIN detached from the navy yard, Norfolk, and ordered to the U. S. S. Richmond.

PASSED ASSISTANT SURGEON J. T. BRANSFORD to be detached from the Richmond on reporting of his relief, and ordered home.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U. S. ARMY, FROM APRIL 2, 1880, TO APRIL 9, 1880.

By S. O. 74, A. G. O., April 3, 1880, the following changes are made:—

Assistant Surgeon G. P. JAQUETT is relieved from duty in the Department of the South and assigned to temporary duty at David's Island, New York harbor, relieving Surgeon A. K. Smith. Surgeon SMITH, when relieved, will report in person to commanding officer, Department of Arizona, for duty as medical director of that department, relieving Surgeon J. C. McKee. Surgeon McKEE, when relieved, will proceed to New York city, and report arrival to the surgeon-general.

The following-named officers are relieved from duty in the departments set opposite their respective names, and will report in person to the president of the Army Medical Examining Board in New York city for examination for promotion, and upon completion of examination report by letter to the surgeon-general; Assistant Surgeon DANIEL WEISEL, Department of the Columbia;

Assistant Surgeon P. F. HARVEY, Department of Dakota; Assistant Surgeon C. K. WISNE, Department of the Platte.

Assistant Surgeon V. HASARD is relieved from duty in Department of the South, and will report to president of Army Medical Examining Board, New York city, for examination for promotion, and upon completion of examination report in person to commanding general, Department of Texas, for assignment to duty.

The following-named officers are relieved from duty in the departments set opposite their respective names, and will proceed to New York city, reporting arrival to the surgeon-general: Surgeon C. E. GONDARD, Department of Texas; Assistant Surgeon F. MEACHAM, Department of Texas; Assistant Surgeon J. C. AINSWORTH, Department of Arizona; Assistant Surgeon C. E. PRICE, Department of California; Assistant Surgeon M. W. WOOD, Department of the Platte; Assistant Surgeon W. C. SHANNON, Department of Texas.

Assistant Surgeon L. S. TESSON is relieved from duty in Department of Dakota, ordered to St. Louis, Mo., and report arrival to surgeon-general.

Assistant Surgeon W. REED is relieved from duty in Department of Arizona, will proceed to Richmond, Va., and report arrival to surgeon-general.

BOSTON SOCIETY FOR MEDICAL OBSERVATION.—A regular meeting will be held on Monday next, at eight o'clock, in the hall at 19 Boylston Place. Reader, Dr. Denny. Subject, A Medico-Legal Study of Delusions. A. T. CABOT, Secretary.

BOOKS AND PAMPHLETS RECEIVED.—A Text-Book of Physiology. By M. Foster, M. A., M. D., F. R. S. From the third and revised English Edition, with Notes and Additions. By Edward T. Reichert, M. D., Demonstrator of Experimental Therapeutics, University of Pennsylvania. With two hundred and fifty-nine illustrations. Philadelphia: Henry C. Lea's Son & Co. 1880.

History of Medicine in New Jersey, and of its Medical Men, from the Settlement of the Province to A. D. 1800. By Stephen Wickes, A. M., M. D. Newark, N. J. 1879.

Observations on Fatty Heart, comprising Remarks on the Morbid Anatomy, Symptoms and Diagnosis, Prognosis, Etiology, and Treatment. By Henry Kennedy, A. B., M. B. Univ. Dublin. London: Baillière, Tindall & Cox.

Lectures.

CLINICAL LECTURES ON ORTHOPÆDIC SURGERY.¹

DELIVERED AT BELLEVUE HOSPITAL, NEW YORK.

BY LEWIS A. SAYRE, M. D.,

Professor of Orthopædic Surgery and Clinical Surgery in Bellevue Hospital Medical College.

IV. CHRONIC DISEASE AND ANCHYLOSIS OF THE KNEE-JOINT.

GENTLEMEN.—As I have more cases of diseased knee at my command to-day than I can well crowd into one brief hour, I will endeavor to select from them such as I think will be likely to prove of most interest and service to you.

FIBROUS ANCHYLOSIS SUCCESSFULLY TREATED BY BRISEMENT FORCÉ.

The first that I shall introduce is one which you have seen before, but which I now show you again, in order that you may observe the progress that has been made since the treatment was commenced.

You will perhaps remember that four weeks ago to-day this patient was put under chloroform, and operated upon by the method known as *brisement forcé*. I spoke to you at that time of the importance of performing this in the most thorough manner, and so, in order to break up the adhesions completely, I first brought the heel close up to the buttocks, and then forcibly extended the limb; after which I repeated these movements again and again, till the desired object was accomplished. Then, you remember, I dwelt with special emphasis on the proper way of carrying out the after-treatment. Strips of adhesive plaster were adjusted on the sides of the leg, and secured by means of a roller, for the purpose of making extension, and the whole knee was neatly strapped with the same; the precaution of filling in the popliteal space with padding having first been adopted, in order to protect the tendons on either side. Then the roller was carried on up the thigh, but at the junction of the lower and middle thirds of the latter a piece of sponge of about the size of a man's thumb was placed over the femoral artery, so as to make partial compression of that vessel, and thus diminish the supply of blood to the knee-joint. This regulation of the blood supply is a matter of some delicacy, and great caution should always be used in applying the pressure, lest too great an amount of it should be brought to bear. Over the whole a plaster-of-Paris bandage was then placed, in order to keep the parts in a state of absolute rest, and this was allowed to remain undisturbed for about ten days. The operation was followed by no febrile reaction whatever; and this, I may say, has universally been the case in every instance since I have adopted this method of treatment.

Steady extension was kept up, and at the end of the ten days the bandages and adhesive strips were removed; when, after a very slight movement of the parts, the joint was again locked up as before, the dressing being precisely the same, with the exception that the sponge compress was not again placed over the femoral artery. After a few days longer, the knee was again uncovered, and an anæsthetic having been administered free movements of flexion and extension were once more made. A brief interval of rest was

allowed, and since then passive motion and frictions have been practiced daily. In making these passive movements I have found it of considerable service to observe the following rule: If the pain caused by these lasts at any time for more than twenty-four hours, the surgeon may know that he has carried them a little too far. The parts should then be given perfect rest for a short time; after which the movements should be renewed, but with less force employed.

To-day, you see, the man is able to flex and extend the limb voluntarily to a very considerable extent, and the passive movements should now be increased from day to day, until a complete recovery has been secured. I would recommend, also, that about once a week the patient should be put under chloroform, and more forcible motion made by the house-surgeon. From the marked improvement that has already taken place in the case, I have no doubt that in the course of another month he will have a perfectly good leg.

[This patient left the hospital the 1st of April with almost perfect motion.]

EXTRA-CAPSULAR ABSCESS IN A KNEE FORMERLY THE SEAT OF JOINT DISEASE, BUT NOW ENTIRELY FREE FROM IT.

The next case is interesting as an instance of an extra-capsular affection in a knee, which was formerly the seat of well-marked joint disease, but in which the joint is now entirely free from trouble. The boy was here a week ago, complaining of his left knee; and when we came to examine it we found a fluctuating swelling over its anterior surface. On first looking at it, one would have been very apt to suppose that this was caused by an ordinary suppurating synovitis of the knee; but a more careful examination showed that the latter was certainly not the trouble present. In the first place, when we pressed upon the joint from above, below, and at the side, it gave the patient no pain. Again, pressure upon and movements of the patella likewise gave rise to no pain. The motion of the joint, however, was limited.

On inquiring into the past history of the case, I ascertained that two years ago the boy had had an acute synovitis of this knee, and that five months since he had been discharged from the out-door department of the hospital, entirely cured of this. After that, he was struck one day on the same knee with a brick, thrown by a boy; and the diagnosis that I arrived at was extra-capsular abscess resulting from the injury thus inflicted. There could be felt, however, on the inner side of the knee a circular depression, which seemed to penetrate quite deeply, and which might possibly be found to communicate with the joint; though this was not probable. Such being the diagnosis, I determined to evacuate the abscess. I first endeavored to accomplish this by means of the aspirator; but no fluid whatever came away. I did not conclude, however, that on this account there was no fluid present, but merely that it was of too great consistence to flow through the middle of the aspirator. Hence, having no doubt in my mind that the pus was there, and remembering the old adage that an empty house is always better than a bad tenant, I made a free incision with the knife; and it immediately became apparent why no aspirator could ever have evacuated the abscess. In addition to a considerable quantity of very thick pus, there were enormous sloughs of the connective tissue and muscles, which had been actually

¹ Reported for the JOURNAL.

cut in two by the brick, although the integument had remained intact. Here, then, was abundant evidence that something with a comparatively sharp edge must have struck the knee while bent and the muscles were in a state of tension. The cavity thus made by the severing of the latter was found to extend almost down to the bone; but the joint itself remained free from all injury. After cleaning this out thoroughly, I filled it with Peruvian balsam, and then packed the wound with oakum.

To-day, on removing the dressing, we find in it a large white slough of muscle, which has been caused by the stimulating qualities of the Peruvian balsam; and when this is cleared away you can see distinctly the cut ends of the tendons and the sartorius and vastus internus muscles, which are now found to be red and healthy-looking. In the free space that is thus left between these severed parts granulation will go on until it is completely filled up, and after a little while the leg will be as good as it was before. The same dressing of Peruvian balsam and oakum will be continued for the present.

I will next show you a well-marked case of

CHRONIC INFLAMMATION OF THE KNEE-JOINT.

This affection may result from a wrench, bruise, or other injury, which may be so slight as scarcely to attract the patient's attention at the time. The woman who is now before you (and whom some of you saw a week and a half ago), while carrying a heavy basket, slipped and fell, striking her knee. She felt a sensation as of something giving way about the joint at the time, but after resting a while she was able to walk to her home. The knee began to trouble her more and more, however, and at the end of a month she had to be removed to a hospital. Here it was found that serious effusion had taken place into the joint, and an extension power of twenty-five pounds was applied. This not only gave her no relief from the pain from which she constantly suffered, but really increased it to such an extent that the treatment had to be abandoned, and the knee was put up in plaster of Paris instead. This likewise gave her no relief, and there was constant spasm in the part. The reason that the extension did not do her good was simply because it was not applied in the proper direction, and it was therefore given out as a case in which Sayre's treatment had conspicuously failed. It was not my treatment at all, however, as you will all soon appreciate.

Now I want you to notice the appearance and position of this limb very carefully, as you have here a very excellent opportunity to study the prominent characteristics of chronic inflammation of the knee-joint. The leg, you will observe, is flexed at nearly a right angle, while the peculiar deformity produced by this affection is very strongly marked. This consists in subluxation and rotation outward of the tibia, which is effected by the constant contraction of the biceps muscle at one spot, and the absorption to a greater or less degree of the external condyle of the femur in consequence of this. In cases where excision of the knee-joint is necessary, it is in this portion of the femur and the outer surface of the tibia that the bone disease is found to be mainly located. In performing such an operation it is always well to bear in mind Bryant's rule, to remove the smallest possible portion of diseased tissue that will answer the purpose for which it is undertaken.

As one of the great sources of trouble in this affection is muscular contraction, local treatment becomes an essential matter, and we resort to extension and counter-extension for the purpose of overcoming the deformity and relieving the pain present. If we do not adopt this course the disease progresses until excision or amputation becomes necessary, or else ankylosis of the joint in a very bad position results. What I want to impress especially upon you at this point is the importance of getting the limb into that position which affords the best opportunity for correcting the existing deformity, and in which the patient will be most free from pain, and then of keeping it there. As is ordinarily the case in this disease, you observe that there is present here the most exquisite sensitiveness of the part, and hence great care must be taken to *make the necessary extension in the direction that affords the most perfect relief to the patient.* The rule is that it should be made in a line corresponding with the degree of deformity which in any case may have been arrived at. Here, if we practice straight traction, we will nearly set the woman crazy, because, there being partial luxation of the tibia and absorption of the head of the fibula, it brings the latter against the femur, which gives rise to the most intense agony. When now, however, I make extension in the proper direction, and at the same time press up the fibula with my hand placed under the leg, the most complete and immediate relief is afforded, as you perceive, for the patient at once gives a grunt of comfort, which is unmistakable in its significance.

The question then is how to secure the limb in this desirable position; and this I will next proceed to explain and illustrate to you. In the first place, we apply strips of adhesive plaster, about an inch in width, all around the limb, and reaching from just below the knee to the ankle; and then secure these by means of a roller bandage, which is carried down to a point about four inches above the latter joint. The ends of all the plaster strips are left loose, for the purpose of making extension when the required instrument is put in position. In like manner, plaster strips, of somewhat greater width and extending upward for a number of inches, are placed around the thigh, and secured by means of a roller.

As I have none of my regular instruments for making extension of the knee-joint on hand that are sufficiently large to suit this case, I will apply here one of those cheap tin instruments which were first suggested by Dr. Rusch, a graduate of Bellevue, and which can be constructed by any ordinary tin-smith. This consists simply of two collars of tin, with projecting ears on either side, into which rods of wood are to be fitted. The ears at the sides of the larger collar, which is intended for the thigh, are swivel-jointed, so that the knee may be secured in any position that we desire. This large collar is first slipped up the thigh as far as it will go, and retained by reversing the adhesive strips over it. In turning these back, care should be taken to do this at the same time before and behind, so that the tin will not become tipped, and thus cut into the limb. The plaster having all been reversed, a roller is placed over it.

The ring for the leg has to be jointed, in order to admit of its passing over the foot and ankle. It is secured in position by the adhesive strips and roller in the same way as that upon the thigh; and in them finally slip the wooden rods into the sockets of the

projecting ears of the collars. The amount of extension is regulated by means of little pins, which fit into holes near the upper ends of the rods; of which there are several, at short distances from each other, so that any degree of extending force desired can be obtained. Of course, this is a very rough contrivance; but if proper care is used in its adjustment, it can be made practically to answer all the important purposes of the more elegant and expensive instruments devised by me. During its application, however, it is impossible to avoid occasioning the patient considerable more pain than in the case of the latter.

The next procedure is to strap the knee as tightly as possible with adhesive strips, for the purpose of promoting absorption of the deposition in and around the joint. In doing this, we must cover it completely; applying the plaster evenly and carefully, and finally making still further pressure by means of a roller over the whole. Having now done all this, we find that the patient is still not yet perfectly relieved from pain. There remains one thing more to be done, and that is to apply an additional bandage in such a way around the bars of the instrument and the limb above the knee that the femur will be forced backward, and another one below the knee in such a way that the action will be reversed and the tibia forced forward. At length we have succeeded in rendering our patient perfectly comfortable; and the great advantage of such a contrivance as this is that it enables us to maintain the limb in this same comfortable position indefinitely.

We have rendered her comfortable, because we have thus secured our two lines of extension: the first by the adhesive strips, drawing the diseased surfaces of the joint apart from each other; and the second by the bandages, which force the femur backward and the tibia forward, and so act in overcoming the existing deformity. I have thus endeavored to point out to you the principles which are to govern you in the treatment of chronic disease of the knee. Of course, their application with a rough apparatus like this requires more care than in a nicely adjusted instrument, such as I ordinarily employ; but the great fact remains, nevertheless, that when the extension had been carried to a sufficient degree and in the proper directions the patient became entirely free from pain, which shows that the end desired has been attained. In a case like this the double extension previously described should be kept up for some time while the patient is lying in bed, before the attempt is made to apply an instrument; and this has already been done here.

Now, however, this patient is capable of getting up and going out-doors with the assistance of crutches; and this, of course, is a great thing for her general health. She may, perhaps, have to wear an extra high heel on the foot of the unaffected limb, and also resort to crutches on account of her great weight. On account of the great obesity of the patient, this is one of the worst cases for the treatment that you could meet with, as it is impossible to get as much purchase upon the thigh as we could desire; but I have no doubt that, notwithstanding this, and notwithstanding the crudity of the instrument that has been applied here, the result will be quite a satisfactory one.

[One week later the patient was again brought before the class, and this time she walked into the arena herself, assisted by crutches. Owing to the great weight of the woman, and the shortness and thickness

of her thigh, it had been found difficult to keep the improvised instrument above described properly adjusted, and hence it had been deemed advisable to substitute for it one of Dr. Sayre's regular knee-joint instruments with a ratchet moved by means of a key. This had been applied the day following the lecture by Dr. Scudder, the house surgeon, and ever since the patient had remained perfectly comfortable. When seen on this occasion, the most marked improvement had taken place in the position of the affected limb, and the diseased joint itself was found to have improved already to such an extent that when the extending force was temporarily withdrawn almost entirely it occasioned her but little inconvenience; while previously such a procedure would have given rise to the most intense suffering. The case was doing altogether better, therefore, than could have been reasonably anticipated.]

ANCHYLOSIS DUE TO EXTRA-CAPSULAR DISEASE.

I have now finally to show you an instructive case, which it will be of great interest to contrast with the first presented; and I only regret that the patient did not arrive here a little earlier, in order that I might have brought the one in immediately after the other. This gentleman was first seen by me in the year 1876. He was then forty-one, and it was supposed that he had had disease of the knee-joint ever since he was thirteen years of age. After a very careful examination, however, I ascertained that the joint was not affected at that time, and came to the conclusion that in all probability it never had been. There were large sinuses all about the knee; but when I held the femur still, I could press the tibia firmly up against it without causing the patient any pain, and the same was true when I made pressure over the patella. So, also, no pain was produced when I pressed upon the outer portion of the head of the tibia, just over the insertions of the coronary ligaments. It is at this point that in chronic disease of the knee-joint the pain is always the most acute and the most easily developed; and hence I felt positive that the joint itself was not affected.

The real difficulty that was present was an extra-capsular abscess, which was now burrowing in different directions, and which had originally resulted from an inflammation of the bursa situated beneath the *quadriceps femoris* muscle. The only thing to be done was to make free incisions through the parts, but being taken ill about that time myself, the case was handed over to the care of the late Prof. A. B. Crosby. With the concurrence and assistance of Professor Wood he carried out this treatment, and the result was an excellent cure in a comparatively short time.

A few days ago, however, he came to me with ankylosis of the knee, and it is for this that he is now seeking relief. On examining the part, we notice first the large cicatrices of the free incisions that were made, and find that there is a well-marked ankylosis, though it is of an entirely different character from that which existed in the other case mentioned. In that the ankylosis was almost bony, although as it was incomplete it was possible to overcome it by means of *brisement forcé*; but here it is of a much less serious character, being constituted mainly by cicatricial contraction of the connective tissue. In such a case *brisement forcé* is entirely unequalled for, and it is mainly to impress this upon your minds that I have introduced this patient. Here I am confident that the whole difficulty may be overcome merely by passive and compar-

actively gentle movements repeated perseveringly and systematically, and the rule for making them is the same as in cases of firmer ankylosis after *brisement forcé* has been resorted to: that is, if the pain produced by such passive motion lasts for more than twenty-four hours, too much force has been used, and the parts should be allowed to remain at perfect rest for a time.

On making flexion in this case by placing the patient's knee over my own thigh, I find that considerable improvement has taken place since I first saw it a few days ago. You see that he is actually able to move the joint voluntarily already, and hence we augur the most favorable result here. From this case, taken in connection with the other, we learn, then, that ankylosis may originate from a variety of causes, and that the treatment of the condition should be varied accordingly.

THE SIGNIFICANCE OF ALBUMINURIA AS A SYMPTOM.¹

BY CALVIN ELLIS, M. D.,

Jackson Professor of Clinical Medicine in Harvard University.

CHANGES IN THE BLOOD-VESSELS.

ALTHOUGH we have admitted that albumen escapes from the blood-vessels, we have alluded only incidentally to the condition of the latter, and it still remains for us to ascertain as far as possible *why they become more permeable*. Changes have been described in connection with various forms of disease. We are told that irritating substances, however introduced, may have an irritating effect upon the capillaries themselves (35, p. 265). In acute nephritis it is probable that there is a lesion of the wall of the vessel, though the strongest power of the microscope cannot reveal it to us in the beginning. If, however, recovery does not take place in the early stage, the vessels undergo visible alterations. The muscular walls of the arteries, as well as the coats of the glomerular vessels, are thickened by a hypertrophic process (33, p. 240), and in amyloid disease the change is very striking and characteristic.

These affections introduce a factor the action of which is deeper, more continuous, and more difficult to arrest than where there is a mere variation of pressure or parenchymatous swelling. Hence a return to the normal condition is not so likely (35, p. 265). But we have still to ask *whether the albumen escapes in consequence of the membrane becoming more permeable, or whether it is so modified as to cause obstruction to the circulation*. Stockvis attributes the albuminuria to the latter (11, v. 15, p. 120), while Runeborg (35, p. 65) connects it with the degree of tension or morbid changes. The instrumentality of both has been made evident by facts already cited, confirmed by the experiments of Hermann and Cohnheim (1 v. 9, p. 54), who have shown that *pathological changes in the walls of vessels render them more permeable*. We are also told that inflamed vessels allow a colloidal fluid to pass through under low pressure (103, p. 165). Admitting this, can we indicate the part which each plays in the more complex cases?

In regard to the consequences of simple irritation, they must be merely a matter of conjecture. In nephritis the difficulty is to separate the effects of al-

terations in the blood-vessels from those which belong to other lesions. This indeed is impossible. We can only say that *the quantity of albumen is largest in the inflammatory affections when, all the agencies are at work*, such as fever, change in the vessels and in the interstitial tissue, as well as swelling of the epithelium of the tubuli and venous hyperæmia. At this time the quantity of urine diminishes (35, p. 266), and, as it afterwards increases, the quantity of albumen diminishes. In amyloid degeneration, where the vessels are particularly affected, we have a clearer field, and are told (38, p. 500) that they allow the albumen to pass through more easily than in health. In pure cases of the kind the albuminuria is regarded as the result of serous transudation through the vessels (38, p. 505), though this may be mere assertion. That this form of disease plays an important part here is suggested by the variation from the usual law, albumen appearing with a large amount of urine and high pressure, while the glomeruli are certainly most gravely diseased (35, p. 268).

CHANGES IN THE BLOOD.

Having now considered the effect of the modifications of the different tissues of the kidneys, we have still to inquire whether some change does not take place in the blood itself which allows its albuminous element to transude. It is useless to dwell upon the theories which maintain that such is the case, as they are entirely without proof (35, p. 71), but there are certain facts bearing upon this point which are worthy of consideration. As might be expected, we have conflicting statements, concerning the blood as a whole as well as its component parts. In the blood as a whole, no change has been shown, except in febrile diseases, and in these it is not such as would be likely to give rise to albuminuria (35, p. 248). The sudden appearance of the latter in some cases will not admit of this explanation (35, p. 227). Although experiments show that a modification of the serum-albumen may facilitate its passage through membranes, we are not aware that such changes ever do take place in the body under similar circumstances (35, p. 68).

CHANGES IN THE AMOUNT OF ALBUMEN IN THE BLOOD.—Much stress has been laid upon the effect of these changes. In investigating this point we are at once confronted with the difficulty that we do not know the exact amount of blood in the body, and are without exact data as to variations in its condition before and after eating, at various ages, and after the use of various articles of food (13, p. 339).

THE DIMINUTION OF ALBUMEN has been supposed to play an important part in the transudation of serum from the vessels (13, p. 539; 22, p. 709), which would show itself in the urine as albuminuria; but experiments most worthy of confidence show the contrary (11, v. 44, p. 217).

AN INCREASE OF ALBUMEN may be temporary and relative, where the blood loses its water and salts, though but little albumen, as in cholera; but this disproportion does not probably last long, as water is taken up very quickly (13, p. 539). In regard to the more persistent increase, though it is difficult to imitate the conditions which obtain in the human body, experiments entitled to the greatest credit (11, 50) seem to show that such is not followed by albuminuria.

The serum of the blood of an ox, mingled with normal urine, was injected into the jugular vein of a dog

(11, v. 44, p. 415); then the serum was injected alone (11, v. 44, p. 304); and afterwards the albuminous urine from patients with organic disease of the kidney was injected under the skin and into the blood of dogs without the appearance of albumen (11, v. 44, p. 519). The same result followed the injection of serous fluid from a case of ascites connected with albuminuria (11, v. 44, p. 522), and of defibrinized blood and serum (11, v. 44, p. 301).

Albumen of eggs and normal urine were then injected, with very different results, as albumen was found (11, v. 44, p. 415); and this albuminous urine being injected into another dog, albumen appeared. The subcutaneous injection of egg-albumen was followed also by the appearance of this form of albumen very soon after the injection, not only in the urine (11, v. 44, p. 304), but also in the saliva.

Lehmann confirmed these results, injecting fluid albumen, which is not generally used as food in large quantities (50, p. 595). Great precautions were taken, an amount of blood equal to that of the fluid introduced being withdrawn before the injection, the effect of which was studied by a manometer. The pressure diminished somewhat after the withdrawal of the blood, and during and after the introduction of an equal amount of a solution of albumen fell still more. It was also noticed, in a minority of the cases in which egg-albumen was introduced into the blood, that the albuminuria was more or less persistent, and that the amount of the albumen secreted was very much greater than that injected (11, v. 44, p. 302). It was supposed that the passage of the egg-albumen through the kidneys produced a change, which allowed the serum-albumen to transude (50, p. 598).

Though Bernard observed albumen in the urine after the injection of serum-albumen, this result was probably owing to its rapid introduction, as other fluids, if thrown in quickly, may produce similar effects (7).

CHANGES IN THE BLOOD CORPUSCLES.—If it be probable, as is stated (22, p. 709), that a solution of the blood corpuscles furnishes a supply of albuminoid matter to the liquor sanguinis in health, we cannot apply even this questionable physiology to any known morbid condition except *hæmoglobulinuria*, the farther consideration of which is unnecessary here.

In regard to the *white corpuscles*, nothing definite is known about the changes they may undergo.

EXCESS OF WATER.—The statement of Roberts (20, p. 120) and others, that the injection of water into the veins is followed by albuminuria, is positively refuted by the experiments of Stockvis (11) and Hermann (39). Both showed that albumen might appear after the injection of water, but they also proved that it was absent when the precaution was taken to withdraw an amount of blood equal to that of the water introduced. Neither did albumen appear under any circumstances, unless in the form of hæmatoglobulin, which passes through the walls of the glomeruli more readily than albumen (39, p. 459). This was of course the product of the dissolution of blood globules; but the quantity of water necessary to produce this result was greater than is ever met with in disease. Indeed, a quantity larger than is ever seen in pathological conditions was introduced without causing a change (11, v. 44, p. 216). When hæmatin was detected it disappeared in about twelve hours with the albumen (39, p. 456).

Though we have not traced albuminuria to any change in the blood except in *hæmoglobulinuria*, it has

been demonstrated that the injection of egg-albumen is followed by its appearance in the urine. We ask, naturally, whether such or some other albuminoid matter may not enter the blood, and be rejected in the way described. The two sources which suggest themselves are the stomach and the tissues. Let us first ascertain the facts in regard to the connection of albuminuria with the ingestion of certain articles of food.

INDIGESTION.

Though not unquestionable (45, p. 333; 52 p. 184), the statements in favor of this are very positive (4) (60) (79, p. 555) (94, p. 929). Beneke found albumen in his urine four times in as many weeks, while suffering from dyspepsia (20). There were no symptoms of renal disease at the time, and he was perfectly well ten years afterwards (52, p. 184).

Among the special aliments, the use of which has been followed by albuminuria, lobsters, crabs (15), cheese, and pastry (4) have been mentioned. The consequences of indulging in such food are not confined necessarily to those who are generally dyspeptic. But no single article of diet has held a more conspicuous place than eggs. Barreswill (4) after eating ten eggs had albuminous urine for twenty-four hours. Though the experiments of Stockvis (11, v. 44, p. 298) upon himself and friend did not corroborate the above, he thought that the exclusive use of albumen might be followed by a different result. Other observations confirm the last view (50, p. 595), and show that, though a large amount given to rabbits and dogs at one time may not have such an effect, the continued use for six or seven days will. A difference was also noticed between the effects of liquid and coagulated albumen, the former being followed by albuminuria, while the latter was not (11, v. 44, p. 298). When there is positive renal disease the amount of albumen may diminish after abstinence from food, and in one extreme case there was scarcely a trace after fourteen hours' fasting (45). It may, on the other hand, increase after taking food (94, p. 929). The albuminuria may manifest itself, at times, only in connection with some predisposing cause: thus in bronchocele, where it is not infrequent, it may be noticed after a large meal eaten hurriedly (4). A striking example was afforded by a case of temporary albuminuria in a young man (57), whose urine was normal while he was in bed. On rising and taking milk only, it would continue so, but after eating a piece of bread the albumen would appear. As he improved, while lying in bed, meat even could be eaten without any change in the urine.

The albuminuria of *bronchocele* has also been attributed in part (4) to indigestion, as patients afflicted with this disease often have a great craving for food, and the change in the urine may follow a heavy meal which has been preceded by long fasting, the absorption being very rapid. We must admit, however, the action of some other agency at times, shown in a series of cases of temporary albuminuria occurring after the longest fast before the principal meal (97, p. 356). But if we admit that the introduction of certain kinds of food, under certain circumstances, is followed by the appearance of albumen in the urine, can we show why it appears? Can we trace it through the different channels of the body, and indicate the point where the usual metamorphosis fails?

Shall we accept the general statement of Parkes (45) that albumen undergoes great transformations

after its passage from the stomach, and that a large amount disappears in its passage through the liver, and conclude that such transformations may not take place, and that it in consequence appears in the urine? Or shall we consider the question settled by the explicit declaration of Robin (42, p. 102) that the liquefied albumen enters the circulation under the form of peptone and albuminose, through the vena portæ and lacteals, and that these substances are changed in the blood-vessels into plasmin and serine; or that albumen should be changed into uric acid (35, p. 71); and that if these changes do not take place albuminuria is the consequence? In such difficult questions it is impossible for the reader to distinguish the boundary between plausible conjecture and true demonstration. *It certainly cannot be claimed that the transformations of albuminoid matters in their passage through the body are settled physiological facts.*

DERIVATION FROM THE TISSUES.

In connection with this appearance of albumen as a result of indigestion, we may speak of the so-called *chylous urine*. This is very rare here, occurring particularly in tropical regions, and is but little understood. The urine is said to have the appearance of milk, and may contain colored and colorless blood corpuscles, with fibrin, but no casts. It has been seen in persons perfectly healthy, in nursing women, and after great fatigue (45, p. 358). It is supposed that some of the ingredients of the food pass into the blood, so that the serum becomes milky (45, p. 359), partly from finely divided fat, partly or perhaps solely from finely divided albuminous substance (45, p. 358). The urine may then also appear milky from the presence of the same materials.

In regard to the derivation of albumen from the tissues, *we can speak with still less certainty*; indeed, very little is known about the matter. If it be true that in the starvation of animals the urine contains varying amounts of albumen (13, p. 530), we might assume that this was necessarily derived from the tissues; but in the presence of so many changes in the body at this time, such an inference would be unwarrantable.

With the subject of changes in the blood we may properly class some instances in which matters not usually found in the blood are mingled with it.

INTRAVENOUS INJECTION OF MILK (75).—In the two cases reported, five and six ounces of milk were injected in anemia and Addison's disease. In the last a large amount of albumen appeared in the urine, but we are not informed about the condition of the latter before, and the fact needs corroboration. Admitting, however, that we have an instance of cause and effect, we must remember that the mere injection of water may have a similar result, unless proper precautions are taken.

BILE.—Numerous cases show that the urine may become albuminous when the coloring matter and perhaps some other ingredients of the bile are passing off through the kidneys (9) (94, p. 929), both when the absorption is connected with temporary obstruction of the duct, as in gastro duodenitis, as in other forms of disease, where the obstruction is permanent and the result fatal.

With this there may be casts, but all morbid signs disappear with the coloring matter. In acute yellow atrophy, however, albumen has almost always been

absent (45, p. 285). Excluding other morbid conditions which may coexist, the effect seems to be traceable to local irritation.

SEPTICÆMIA AND KINDRED DISEASE.—In addition to the albuminuria, which may be traced to disease of the kidneys themselves, or some other morbid processes, so common in septicæmia, we may have some *alteration in the blood attended by the dissolution of red corpuscles and the escape of the coloring matter* (20, p. 123). *We may now conclude that albuminuria never depends upon a variation in the character of the blood, unless traceable to the injection of some foreign matter, the presence of the products of faulty digestion or of some ingredients of the bile, or dissolution of the blood discs.*

APPLICATION OF FACTS TO VARIOUS MORBID CONDITIONS.

Having considered the various ascertainable causes of albuminuria, we are prepared to apply this knowledge to the solution of the large number of remaining instances in which this peculiarity has occurred, and in this way test the correctness of the views advanced.

We might group these separate examples under various heads, and establish a kind of approximative classification, according to the previous divisions of the subject; but as the explanation of the symptom in various diseases is to be sought not by reference of the latter to each other as much as to principles already laid down, we shall again adopt an alphabetical arrangement, which will, at least, be of use as an index. Some included in the first table are not introduced again here, as there is nothing to be added to the mere mention of their occurrence.

ACID CARBOLIC.—This being generally used as an external application, the statements probably refer to its absorption from various surfaces. Albuminuria has been seen, though it is not constant (1, v. 15, p. 230). The effect is probably owing to the irritating action of the drug, as it is secreted with the urine. We may infer from this that the condition of the kidney resembles that of *acute nephritis*, but we are without positive information in regard to this. Though granular degeneration is spoken of by Neumann (74), as this change requires time, we may suspect that it existed independently.

ACID HYDROCYANIC.—Having only the bare statement that albuminuria occurs in poisoning with this (16, v. 2, p. 364), with no knowledge of the condition of the kidneys, we can merely surmise that the result is *attributable to the profound impression produced upon the nervous system.*

ACID MURIATIC.—It is sufficient to say that the consequences of poisoning by this are *similar to those described in connection with sulphuric acid.*

ACID NITRIC.—See Sulphuric Acid.

ACID SALICYLIC.—Too little is known about this to express decided opinions, but it seems to be not uncommon for both albumen and blood to make their appearance after large doses (35, p. 256).

ACID SULPHURIC.—While it is admitted that albuminuria occurs, there is a want of unanimity about the anatomical changes, which are variable or even wanting, as is shown by experiments and clinical cases, and necessarily so, as the extent differs according to the amount of the poisonous agent. It is, however, impossible to doubt the accuracy of the following statements: In two cases of poisoning, reported by Leyden and Munk (12), proving fatal in twelve and eighteen

hours, albumen was found in one only two hours after taking the acid; in another about twelve hours after. The quantity was large, but on the following day had diminished very much. The acid leaves the body in the form of sulphates, and escapes within a very short time (1, v. 15, p. 38). It causes direct irritation of the renal tissue, and we find in consequence of this (12) blood, granular epithelium, hyaline and granular casts. An examination of the kidney in one case after death showed granular epithelium, dilated tubuli filled with numerous opaque cells, and more or less fatty degeneration of the cells. The glomeruli were large and filled with nuclei. The interstices between the tubuli were larger than usual, and contained many nuclei. In an experiment upon a dog, albumen appeared in the urine four hours after the acid was given, and with it blood corpuscles, numerous cell-elements, cylinder epithelium, and much finely granular detritus. On the following day the same elements were found, but decidedly less albumen. The animal was killed on the second day by opening the carotid. The changes in the kidneys were similar to those previously described in man.

We have here the general effect upon the circulation through the disturbance of the nervous system shown in the diminished force of the pulse, collapse, etc., at times hæmoglobinuria (35, p. 256), and morphological changes in the kidneys, of such a character that they may be classified with those of acute parenchymatous nephritis.

ALBUMINURIA, whatever its origin, is often accompanied by disturbance of the nervous system and the heart, such as delirium, stupor, collapse, and increased frequency of the pulse (35, p. 253). This seems to be an additional cause, subordinate to the original disease, but sufficient to aggravate the trouble.

ALCOHOL.—This agent is so frequently spoken of as an exciting cause it is somewhat surprising to see the *dearth of real facts* upon which statements ought to be based. In acute alcohol-poisoning albumen is seen only occasionally, and as a trace (35, p. 245). In chronic alcoholism without delirium, it may appear, but only rarely and in small quantity (81, p. 759); even in great drunkards there may be only a slight opacity. In delirium tremens, which shows at least excessive use, it was found in forty per cent. only, and here it was dependent upon the attack, lasted perhaps several days, and disappeared at once after sound sleep and the restoration of the mental faculties. The amount was in proportion to the delirium, and not muscular motion, as it was seen when the patients were quiet in bed (35, p. 245). Where the delirium was mild it might be absent (81, p. 758). Some hyaline or perhaps finely granular casts were occasionally found, but an examination of many cases which terminated fatally showed no lesion of the kidneys.

The result seems fairly attributable to some affection of the nervous system, as it depends upon the extent of the disturbance of this, and is temporary (35, p. 245). If there be, occasionally, renal disease, it may act as an additional cause.

ANÆMIA.—Nothing has been elicited by this inquiry into the changes of the blood itself which explains the albuminuria, mentioned in connection with so-called *anæmia*; but the term is used so loosely, it conveys no idea of the special features of any case, and it is upon these alone that we can base an opinion. Even in cases of *pernicious anæmia* the albuminuria is only

transient, the quantity of albumen is very small (93), and its presence might be attributed to the failure of the power of the heart (35, p. 259). Of course when blood escapes, with the formation of petechiæ, the cause is obvious, and when there is dropsy we trace the change in the urine to the escape of serum-albumen.

ANTIMONY.—We may also have blood as well as albumen (29, p. 145), and the same fatty degeneration of the epithelium as in poisoning by phosphorus and arsenic (101, p. 167). These seem to be owing to the direct irritation of the drug, as it escapes in part or altogether through the kidneys, and is found in the urine (52, p. 140).

ARSENIC.—Though arsenic escapes particularly through the kidneys (29, p. 358), the amount of albumen is very small, and there is the same want of uniformity in the observed results as in poisoning by phosphorus (1, v. 15, p. 340) (11). The fatty degeneration of the cells, found in experiments, has also been noticed in man (34, v. 99, p. 358) (32, p. 77).

ARSENIURETED HYDROGEN.—Vogel states (52, p. 117) that the inhalation of this gas is followed by albuminuria and the passage of very dark or blackish urine, attributable probably to the *dissolution of blood corpuscles*. If the latter be true the source of the albumen is obvious.

ASPHYXIA (16, v. 2, p. 863).—This is merely mentioned, without any accompanying facts, and we can only say that it must act by disturbing the circulation, and with this the nervous system.

BILE.—See page to follow.

BLOOD.—See page 363.

BRAIN, CONCUSSION OF.—The details given in connection with this (44, p. 143), where the albumen disappeared soon after the accident, show that its appearance was not dependent upon other disease, and was probably connected with the great disturbance of the nervous system.

BRAIN, HÆMORRHAGE INTO.—The evidence in connection with this is ample, but conflicting. The details given by Ollivier, however, are of such a character as to beget confidence in their accuracy (73). The albumen made its appearance perhaps half an hour after the attack; was at first scanty, then increased, and disappeared at the end of twenty-four hours, though at times it persisted till death. There was neither blood, nor pus, nor evidence of Bright's disease in the cases upon which the statements were based. It was attributed to paralysis of the vaso-motor nerves of the kidneys. Richter (80) failed to find albumen after many examinations.

BRONCHITIS.—Albuminuria is frequent in severe cases, though temporary. We have here fever with its consequences, and perhaps some tissue changes in the kidneys.

BURNS.—An extensive burn, if the patients live long enough, is likely to be followed by *inflammation of the kidneys*. This observation in man has been confirmed by Ponfick's experiments on animals (71). He showed that burns were followed in a few minutes by a *diminution of urine and an alteration of the blood*, the red corpuscles breaking up into minute colored particles, which were transported into various organs, and escaped from the kidneys as hæmoglobin. There were found also nephritis, fatty epithelium, and peculiar colored casts, with obstruction of the tubuli.

CARBONIC OXIDE.—As the urine is at the same

time saccharine, we have a complication; but the albuminuria lasts only a few days, and disappears with the other symptoms of poisoning (1, v. 15, p. 170). When death follows we have *hyperæmia, parenchymatous swelling, and fatty degeneration of the cell elements, as in poisoning by phosphorus and arsenic* (1, v. 15, p. 170). The albuminuria therefore admits of the same explanation.

CANTHARIDES.—Notwithstanding the adverse statements, it seems to be demonstrated that albuminuria may occur (1, v. 9, p. 173), and that the irritating active principle of the drug is eliminated by the kidneys. As it may excite inflammation of the bladder (29, p. 535), this last source of albumen must not be overlooked. The amount of albumen may be considerable, but it disappears when the exciting cause is removed, though a case is reported in which it persisted, with blood corpuscles and casts, for three weeks after the cantharides had been stopped (1, v. 9, p. 173). As patients generally recover, it is not easy to say what the true condition of the kidneys is (1, v. 9, p. 172), though hyperæmia (29, p. 536) and true inflammation are mentioned. But if we can draw an inference from the results of experiments on animals the histological changes may be marked. Lassar (101, p. 167) indicates that such may be the case. Browicz (55) injected cantharides subcutaneously, and after a time examined the kidneys. They were more or less swollen, and the convoluted tubes appeared to be closed by the opaque and swollen epithelium. The loops of the vessels were considerably enlarged, and between these and the capsule was a deposit of hyaline and finely granular matter which seemed to compress the vessels. In the interstitial tissue were some white cells, and perhaps groups of the same.

CATARH, INTESTINAL.—Cases are mentioned, particularly in elderly persons (76), in which the albumen appeared even a few hours after the commencement of the attack, and the urine at the same time diminished in quantity. This occurred whether the dejections were numerous or not, in connection with slight symptoms of collapse, and disappeared a few days after the catarrh. Though the temperature was at times higher than normal, this increase was not necessary (77).

At times the morbid elements from the tubuli were as marked as in acute nephritis, and again very few were seen. The casts were generally hyaline, though sometimes granular. Their appearance did not depend upon the number of dejections, though perhaps on their frequency. A little blood might also be seen, with some epithelium and pus corpuscles. Where the casts were numerous the albumen would be obvious by ordinary tests, but otherwise it might be difficult to find, or wanting. The pulse was smaller than usual and less full. The patients all recovered, and the intestinal trouble did not seem to be prolonged or intensified by the renal disease. There were no complications nor indications of any other diseases.

Such a condition would have a tendency to lessen the power of the heart, and consequently diminish pressure on the glomeruli (35, p. 237). The indications of temporary structural change in the kidneys add, of course, another agent for the production of albuminuria.

CHLOROFORM, INHALATION OF.—Careful observations on human beings and a dog (49, p. 437) show that albumen may appear during the deep narcosis

from this drug, lasting from half an hour to an hour and a half, but it is by no means constant.

This is in conformity with what we should expect, if we bear in mind the sedative power of the agent over the heart.

CHLOROSIS.—In this affection albuminuria is uncommon (45, p. 836).

CHOLERA.—Though not always present, it is common, and may be found in slight cases (45, p. 801). Detected at various periods (35, p. 238; 16, v. 2, p. 862; 58, p. 296), it disappears in from one to four days (45, p. 306), according to the severity of the case. The amount of albumen cannot be stated very accurately, but it seems to be small (1, v. 9, p. 212), and to bear a certain general relation to the cold stage (45, p. 301).

In some cases, although the circulation is restored, the urine is secreted in very small quantity, or not at all (1, v. 9, p. 55). There may also be found casts and renal epithelium (45, p. 308).

The attempt has been made to explain the albuminuria by the supposed stagnation of the thickened blood in the capillaries, but, unfortunately, this has not been demonstrated (1, v. 9, p. 55). Hemorrhagic infarct might be a sufficient cause, where present, but it is by no means an essential feature. It is quite as reasonable to attribute it to the depressing effect on the nervous system of the vomiting and purging, and this, with the great loss of water, would tend to diminish the pressure on the glomeruli.

CHYLE.—See page to follow.

CIRRHOSIS.—Albumen is seldom found in simple cases (45, p. 327). When it is, there is interference with the circulation of the kidneys, and almost always a diminished secretion of urine (4). This explanation seems insufficient, however, if we bear in mind the tolerance of much greater obstruction, without the appearance of albumen.

COLD.—Many of the cases in which albuminuria is attributed to cold are too incomplete to permit their acceptance as necessarily pure examples of the effect of this single agent, and some (9; 16, v. 2, p. 861) seem to be merely instances of renal disease produced by exposure, and the albuminuria must be attributed to this lesion of the kidneys themselves. But in the following the condition of the urine may be fairly connected with exposure to cold, though we cannot eliminate altogether the effects of exertion.

COLD BATHING.—Dr. G. Johnson (9) has reported the case of three healthy medical students, from twenty-two to twenty-five years old, who took cold baths in the months of June, July, August, and September, remaining in the water from a quarter to half an hour and an hour. The one who remained the shortest time had a sensation of fatigue and headache. The others noticed no special symptoms. In the first, the urine examined four hours after the bath contained albumen, which in a few hours more was much less, and on the following day absent, and so continued for a week, when, after another bath, the same symptoms returned with albumen, which was found to be present in almost every portion of urine passed for twenty days, when it disappeared.

In the second case, the urine passed after a bath contained a sixth of albumen. It was not tested again for three or four days, but was then normal.

In the third case the urine examined on three occasions before taking a sea bath, lasting from a quarter

to a half hour, was found normal. An examination after the bath showed a moderate amount of albumen, which disappeared in a few hours.

Four other students, after bathing from half an hour to an hour, and, on one occasion, for an hour and a half, detected no albumen in the urine. No casts were seen in any of the cases. The specific gravity was not taken.

In the fourth case, a boy sixteen years old had for some time bathed in the sea almost daily from half to three quarters of an hour; had felt fatigued and chilled on coming out of the water, and had once vomited. A few days after, when seen on June 28th, he was pale and languid, and the urine contained "an eighth" of albumen without casts. When next seen, on September 23d, there was only a trace of albumen, and this was absent on October 23d. There had been no previous illness except diphtheria, ten years before.

Dr. Johnson also stated that a bath of ten minutes in cold water might bring on albuminuria in some persons, and that the amount might be very much increased by prolonging the bath half an hour. In an article recently published (94, p. 929) the same writer reports observations which corroborate the above, and show that permanent disease may be traced to the effect of cold.

A number of writers concur in attributing the albuminuria to the impression produced upon the nervous system, through which the vaso-motor nerves are influenced (11, v. 45, p. 219; 16, v. 2, p. 864; 35, p. 245). It has been noticed that when an animal is cooled down to 68° F. the pulsations of the heart fall to sixteen or twenty, the respiration becomes very superficial, and the secretion of urine ceases (67). But the intensity of this action may be such as to produce structural changes, as is shown by the experiments of Lassar (100), who, after using every precaution to secure healthy rabbits, shaved them, allowed them to remain for a time in a high temperature, and then suddenly plunged them into ice-cold water. After an immersion of from one to three minutes, there was considerable fall of temperature, and the animals trembled for hours, though placed in a warm atmosphere. Not long after they appeared well, but, in one or two days, more or less albumen was found in the urine, with a few hyaline casts. This in many cases lasted but a few days, when it gradually diminished and disappeared, though frequently it persisted some weeks, and death followed. A repetition of the experiments after recovery was followed by the same series of symptoms, two rabbits being subjected to three different trials of the kind, with the same result and a favorable termination. On an examination of those which died, interstitial inflammation was found in various organs, especially the kidneys and liver, but the parenchyma of organs was not particularly affected. The vessels were enormously dilated in the lungs and liver, the arteries filled with thrombi, and in the neighborhood of the veins were white blood globules. Experiments upon young dogs showed the same effects. These anatomical changes must play an important part in the causation of the albuminuria.

In COLLAPSE we have a diminution in the quantity of urine, and often albumen; but the quantity of urine increases and the albumen disappears as the power of the heart increases (35, p. 259). This is in accordance with the view that connects albuminuria at times with diminished power of the heart.

CONVULSIONS.—Albumen is likely to follow these under any circumstances.—The occurrence of such as

are common in connection with the shrunken kidney may be followed by an increase of albumen (35, p. 269), showing clearly the influence of this perturbation of the nervous system.

DELIRIUM.—See Collapse.

DIABETES.—The frequency varies (45, p. 356), but it is not uncommon, though the amount is seldom above 0.2. It sometimes appears towards the close of cases in which tuberculosis has supervened. The changes indicative of nephritis are not necessarily present, nor is there any lesion which is peculiar to it. The causes are not perfectly clear. There may be, in addition to tuberculosis, already mentioned, great weakness, or true Bright's disease; but we may be sure that sugar is not the exciting cause, for albuminuria is seen only in a part of the patients, and for a short time even in these (35, p. 259).

DIARRHŒA.—See Catarrh Intestinal, page 392.

DIARRHŒA, CHOLERÆ.—We may have albuminuria in those attacks of diarrhœa and vomiting, which somewhat resemble true cholera, where there is no specific cause (35, p. 239). In exhausting cases of the kind in children, the first urine which is secreted contains albumen, but the latter diminishes as the flow increases.

DIPHTHERIA.—As epidemics differ in their character, statements must also differ in regard to the frequency and time of the appearance of this complication (1, v. 22, p. 580). The amount is at times very large, and in adults has generally been in proportion to the severity of the disease; but in many cases this has no bearing upon the character or termination, for the disease may be fatal, either by asphyxia or blood-poisoning, without the amount being more than moderate. In rare cases the albumen may be first detected when the local changes are declining. It is not uncommon even in sporadic cases, but is then transient, lasting but a few days, though it may return. It has been known to persist six or eight weeks after severe cases, and in some slight attacks even it may persist for months, with oliguria and inanition, and be accompanied by dropsy. When it is noticed with very slight local trouble, there is reason to anticipate a severe affection. This is shown strongly by the observations of Dickinson (88), which prove that it was rare in the so-called false croup where there was no membrane, and very common in connection with the latter. As there are casts and blood in the urine, with structural change of the kidney, the explanation is simple.

ECLAMPSIA OF INFANTS.—After eliminating the fits which precede the eruptive diseases and those connected with affections of the kidneys, we find but few observations. Weiss (102) and Demme (105), however, report a number of cases in which the amount of the albumen varied with the number and duration of the fits. Casts were rare. We need seek for no other cause than the disturbance of the circulation through the vaso-motor nerves.

EMPHYSEMA.—The effect of this in the production of albuminuria is admitted with more or less qualification (20) (v. 9, p. 43) (45, p. 321) (14). It is certainly infrequent, and necessarily so, for emphysema as such ought not to have any effect upon the renal excretion. It is a question of degree, and if we consider that the marked cases are followed by signs of weakness in the right ventricle (7) and the consequences of cardiac disease the explanation is the same as in the latter.

(To be continued.)

RECENT PROGRESS IN DERMATOLOGY AND SYPHILIS.

BY EDWARD WIGGLESWORTH, M. D.

HISTOLOGY OF MOLLUSCUM SEBACEUM.

The late Tilbury Fox and his brother, T. Colecott Fox, M. B., have examined¹ little tumors of molluscum sebaceum from the faces and bodies of children, and of a nursing mother; also from the scalp of a man of forty-five (a rare site), as well as from a case of general distribution in a man aged sixty. The points at issue are, (1) the origin of the gland-like looking tumors and (2) the source and nature of the so-called mollusc bodies. By means of well-executed wood-cuts they show how they traced the gradually increasing hypertrophy of the gland structure, with concurrent increase of contents and consequent dilatation of the ducts into a large cavity. The enlarging tumors formed capsules by condensation. Leucocytes in excess. The peculiar mollusc bodies were produced simply by a process of extreme vacuolation of the ordinary lining cells of the acini, which process goes on more or less constantly in health. In the cells nearest the centre of the acinus the vacuolation was seen to be complete, and it took place in nearly all the cells; the nuclei disappeared, the vacuole filled with altered sebum,—the supposed colloid substance,—and the concreted mass, dilating the centre and mouth of the acinus, was then mainly constituted by these cells, the peculiar-looking large mollusc bodies. No fungous elements were detected in any fresh specimen. The investigators therefore regard the disease as of the sebaceous glands, consisting in hyperplasia and hyperactivity of the whole gland structure, exhibited not only by the increase in size of the individual acini, and the formation of a little tumor, but in the greater endogenous formation of gland cells, their subsequent vacuolation, and, finally, the formation of the peculiar mollusc bodies by alteration of the sebum forming and collecting in these vacuoles and distending the enlarged cells.

THE EXTRA-GENITAL PRIMARY SCLEROSIS OF SYPHILIS.

Dr. Mracek, v. Sigmund's assistant, calls attention² to the fact, so often stated, that "venereal diseases" are not necessarily venereal. The primary lesion of syphilis may appear upon any part of the body, and by the third or fourth week³ two thirds of such lesions have developed characteristic symptoms. Those beginning with ulceration require from five to six weeks; that is, the incubation and the development of the primary or the general manifestations of syphilis are the same, no matter upon what part of the body the virus has been inoculated, nor by what methods or instruments. The sclerosis disappear rapidly if the patient is attacked by fevers (typhus, erysipelas, etc.), but appear harder and dryer than usual if pthisis is present. Extra-genital primary lesions, often subjected to more favorable conditions than usual as to circulation, and more protected from chemical or mechanical irritation, rarely ulcerate, and may remain for a long time as a nodule in the skin. If such are upon the face, destruction by excessive or repeated cauterization may cause permanent loss of substance and disfiguring cicatrices.

The traumatic ulcers on the borders of the tongue found with carious teeth must not be mistaken, even in cunilingi, or when chronic inflammatory hardening has changed the base or surrounding parts, for syphilis. More readily distinguished are simple, or so-called chancreoid, or scrofulous, or lupous, ulcerations. The tuberculous ulceration of the skin⁴ has an irregular, everted margin, slight elevation above the skin, and an uneven, red, bleeding base with yellow points (miliary tubercle). A sclerosis of the lips⁵ in old people, shining, secreting little, its thin border composed of separate nodular points (ulcus rodens of old surgeons) is to be distinguished chiefly by its long duration. The more rapidly destructive epithelioma has lancinating pains and papillary basis. The papules, ulcerations from pustules, and gummatas, where doubt exists, are diagnosed by the existence of other late lesions. A gumma of the tongue may resemble a primary lesion.⁶ Here other gummatas or their scars may generally be found, or a little patience will enable one to see the rapid degeneration and disintegration from the centre outwards which marks the gummous tumor.

PERMANENT REMOVAL OF SUPERFLUOUS HAIRS.

Dr. Hardaway reiterates⁷ the statements made by him some two years since, before the American Dermatological Association, as to the value of electrolysis in the removal of hairs. A No. 13 cambric needle is attached to any handle; this is connected with the negative wire of a galvanic battery, and a moistened sponge electrode with the positive pole. The patient sits facing a good light. A strong lens is held in the left hand of the operator, while the right inserts the needle into the hair follicle. Then first the patient touches the palm with the sponge electrode. When frothing is observed around the needle, the electrode is first released by the patient (to avoid shock), and the needle then withdrawn. If successful the hair comes out readily; if not, repeat.

MOLLUSCUM VERRUCOSUM.

Professor Hyde, of Chicago, reports a case exhibiting certain rare and peculiar features, a variety of molluscum, and to be classed with some described by Hutchinson, of London, not entirely identical, the characteristics of which differ in a marked degree from those first observed by Bateman, and since studied by later investigators. These are, briefly, an extraordinary multiplicity of small, pointed, white-capped, more or less solid lesions, resembling vesicles in their external appearance, generally destitute of fluid or milky contents, often without a central depressed orifice, and at times intermingled with other lesions, the appearances of which point unmistakably to a sebaceous origin. There were, however, several recurrences of the disease in Professor Hyde's case, which, perhaps, may have taken its origin from the rete bodies by proliferation, rather than from the sebaceous glands. The patient was a very stout, but otherwise healthy, German, aged thirty-five years. Buttocks, thighs, and loins were at first affected by white spots, which disappeared in a year, leaving reddish pigmentations, only to reappear three months later in the same localities and to extend in all directions. There were no subjective sensations. When seen by Professor Hyde

Wochenschr., 1879, No. 18.⁶ Zeitsch. Bericht des k. k. Krankenhauses, 1877.⁷ Philadelphia Medical Times, February 14, 1880.⁸ Reprint from Edinburgh Medical Journal, February, 1880.

the spots were papular, and spared only the head, face, genitals, supra-sacral region, and the feet and legs below the level of the tops of the boots; they were symmetrical in their distribution, and darkest over buttocks and thighs, where a dozen could be counted in a centimetre square. The lesions were pin-head to split-pea sized, projected one to three millimetres, and had a globoid profile. They did not primarily invade the pilary nor sebaceous follicles, involved the entire thickness of the skin, were surrounded by healthy integument, and without infiltration, œdema, or areole of a congestive or inflammatory type. The smallest lesions resembled milium. The largest had a crimson tint, extending to a little less than a millimetre from the base of each, and a waxy, whitish summit. They were elastic on pressure, smooth, translucent, and glistening, without follicular orifice, hilum punctum, or depression, and when pricked exuded a red fluid, which under a one-fifth objective proved to be healthy blood. One pricked spot oozed for twenty minutes. This was in August, 1878, and the patient sweated so that without his coat or waistcoat, the perspiration ran down his body, and dripped from nose and chin. Gradual involution of the lesions of the skin took place as the weather grew cooler, without any treatment. In January, 1879, the eruptive disorder had almost entirely disappeared, leaving purplish hæmorrhagic maculae. As the weather grew warmer the symptoms of the previous year recurred, and by the middle of April were markedly present resting directly upon the purplish maculations still distinguishable as the sequelæ of their predecessors of the past season. By July, however, the lesions present in April had not only failed to develop as formerly, but had disappeared. Microscopical examination of an excised papule showed that it was composed largely of proliferating rete bodies and connective tissue, with an empty vacuole or space visible in the upper portion of the corium, which seemed to connect with certain irregularly branching channels, and of so definite a contour that half the vacuole was in each of two sections. Professor Hyde's case is to be distinguished from Kaposi's case of lymphangioma tuberosum multiplex.¹

SYPHILIS AND DEMENTIA PARALYTICA.

Mendel found,² according to Wernicke,³ in sixty-two autopsies of one hundred and seventy-one male paralytics, one gumma, two cases of Heubner's disease of the arteries, and two cases of syphilis of other organs. In the history of one hundred and eighteen of these one hundred and seventy-one cases of paralysis, twenty were known to have had syphilis; fifty-three cases had no history. In one hundred and twenty-two other cases of brain diseases, of similar age, twenty-one had no history, thirty were syphilitic. Where paralysis existed seventy-six per cent. were syphilitic; and but eighteen per cent. where only other brain diseases were found. Mendel holds that there is a much closer connection between paralysis and syphilis than can be proved by autopsies, although he, like others, has seen no special results from anti-syphilitic treatment.

ÆTIOLOGY OF ERYTHEMA NODOSUM.

Neumann regards,⁴ contrary to the opinion of most writers, erythema nodosum as an idiopathic affection, having nothing in common with E. multiforme except

the name, developing itself, especially in anæmic persons, with light fever or rheumatic pains, and disappearing spontaneously, and not to return, within three to four weeks. The erythematous nodules may, however, also occur as concomitant symptoms of pleuritis, rheumatism, or pyæmia, as illustrated by three cases, which are briefly communicated by Neumann.

TREATMENT OF PALMAR AND PLANTAR SYPHILIS.

Solutions of corrosive sublimate are, according to Sigmund,⁵ preëminently the means for the dispersion of syphilitic new formations of the secondary group, papules, pustules, and scales; but the application must not be left to unskilled hands. With care, scar and pigment formation, in fact the further development of all forms, may be prevented by brushing with a solution (one to fifty to one hundred) and a camel's-hair brush twice or even once daily the spots affected, at the first appearance of erythema or of infiltration of the follicles and papillæ. If the first use of this is made early in the morning it can then be seen in the course of the day whether the skin will bear a repetition of the same lotion or not; or whether it may not be needful, on the contrary, to make some counteracting and soothing application. If so, the best preparation is the solution of acetate of lead in water (one to twenty). With this, one or two hours after brushing with the sublimate solution, compresses are to be well soaked, and at once laid upon the spots. This lessens pain without essentially interfering with the peculiar efficiency of the sublimate. Should pain immediately follow the brushing on of the mercury, the lead lotion may also be at once applied. For each bathing fresh brushes must be used, or the old ones must be well washed out; otherwise the sublimate remaining in the brush after drying will make the next application a too caustic one. Before every new brushing the skin must be washed clean with soap and water. The best vehicle for the sublimate is: for the palms and soles, collodion; for more delicate parts of the body, alcohol; for mucous membranes, ether. When the first is employed a little fresh linseed or other oil should be added to the vehicle, — one part of oil to twenty of collodion. This makes a flexible, elastic covering, permitting motion of the hands and feet without causing cracking of the collodion layer. Sigmund writes for hydr. corr. chl. one, olei liui recentis one, collodion fifteen to twenty-five. This is rubbed upon the lesions on the palms and soles in the morning. At night, white ppt. ointment; hydr. ammoniat. five, ung. simp. twenty-five, is well rubbed in, and gloves and socks used as covering, during the night. For older and more inveterate cases the skin is first to be softened by soap and warm water, lotions and ointments; chaps and cracks to be covered with strips of cloth smeared with emplastr. saponis, empl. hydrarg., of each p. æq., and packed comfortably in compresses. So also local inunction of ung. hydr. at night for ten minutes, and in the morning employment of the same spread on cloth after the brushing on of the collodion. Then gloves and socks by day and night both.

Palmar and plantar syphilis is a late symptom, resists treatment obstinately, lasts long, and tends to relapse. It is often the only existing sign of the presence of the disease, and then needs only local and general hygienic treatment. When other symptoms are present, constitutional specific treatment is demanded.

Cleanliness and good diet are of the utmost importance.

PITYRIASIS RUBRA.

Duhring reports ¹ a case of this rare disease in a laboring man, aged fifty-six, previously healthy. Two years prior to date itching about ears and scalliness. This condition spread in a year over the whole body, was aggravated during the next three months, the hair and nails falling out, and became even worse during the following quarter year. Then the whole skin was thickened, red, and scaly, and itching was universal and constant. He entered the hospital (April 10, 1879) meagre, feeble, and exhausted; the whole body desquamating, a double handful of pea to finger-nail sized papery lamellæ curling up and falling daily; palms infiltrated and soles scaly; fingers like claws with fissures in flexures; eyeballs suffused, injected, watery; lids red and deprived of lashes; never any oozing anywhere; hairs gray, dry, harsh, and scanty; nails soft, bulky, thickened, rough, corrugated, and yellowish; skin burning, but patient chilly, with voracious appetite, having lived on bread and tea for months, "to subdue the inflammation;" bowels constipated; urine normal; evening temperature 37.5° C. The patient has now been six months under treatment by baths, tar, carbolic acid, etc., externally, and potassium, iron, cod-liver oil, arsenic, strychnia, nitric acid, and flaxseed tea in turn, internally. He has gained nineteen pounds, but is relapsing into hebetude, and the disease is little if at all changed. The disease was first described by Devergie, and is very rare. Its etiology is obscure. Pathologically there is simple inflammatory alteration, affecting the upper layers of the skin only, and accompanied by some atrophy of the papillæ. Prognosis must be guarded. Recovery sometimes occurs. Relapses usually take place. [General bandaging with India rubber has been of service in some cases.—*REF.*]

STATISTICS OF SYPHILIS AMONG THE WOMEN OF ST. PETERSBURG.

Dr. Edward Spereck gives ² the results of his studies upon syphilis in a place where the material is extensive and the police control strict, as follows: (1.) All prostitutes cannot be controlled, though in Hamburg and Brussels the police have been more successful than in St. Petersburg, and here than in Paris and Berlin. (2.) The number of public prostitutes is in St. Petersburg disproportionately small as compared with the number of unmarried men. (3.) Here, as elsewhere, women pass from public to private prostitution, and *vice versa*, in accordance entirely with temporary circumstances. (4.) The majority of women adopting this life escape the notice of the police for the first four years. (5.) Registration for the first time of courtesans of years' standing shows this to be true. (6.) The average Cyprian is infected with syphilis within three years after entering upon her trade. Brothels were examined where seven or eight out of ten inmates were thus diseased, although in others there was no inmate in whom the disease was in the actively contagious stage.

The writer emphasizes the fact that during two or three years after infection relapses are common; that a woman with a relapse is dismissed from the hospital

as "cured" as soon as external manifestations have temporarily disappeared; that she then returns to public life a certain and the most frequent cause of the dissemination of syphilis. The infectiousness of the "secondary" stage is not sufficiently regarded. Six sevenths of the cases of syphilis in men are from women with "secondary" symptoms; one seventh only are infected from "primary" lesions. As to prophylaxis, the writer suggests ³ that syphilitic women be allowed to entertain only syphilitic men,—a millenniumistic idea, were it only possible of execution,—or that prostitutes released from hospitals should be quarantined for two or three years. [This would cost for Boston about two hundred and fifty thousand dollars per annum.] About seven hundred prostitutes are annually treated in St. Petersburg. In the orphan asylum about one child in fifty is syphilitic. In the brothels about thirty to forty per cent. of women are constantly in a condition to infect those having to do with them, and the same is true of the unregistered and clandestine "cocotte" class.

WATER FOR DISEASES OF THE SKIN.

Bulkley calls attention ⁴ to the use and abuse of water, externally or internally, plain or mineral, in diseases of the skin. (1.) Abundant bathing serves as a great preventive both of cutaneous diseases and of systemic disorders. Cool or tepid, every morning, followed by vigorous friction, it is a great safeguard against disease. For cleanliness add a warm bath once a week, followed by the cold douche, to quicken the circulation and diminish the danger of "taking cold." Turkish and Russian baths must not be used to excess. They are powerful stimulants, and not the panacea for all bodily ills. But though sluggish, thick skins bear more bathing than common ones, thin and irritable skins, such as tend to itching, articularia, or eczema, bear water less well, and subsequent friction must be avoided. (2.) Ablutions and bathings often remove nature's protective exudations, and do much harm; but for chronic eczemas and erythemas, pruritus ani or vulvæ, onychia, acne, indolent ulcers, and conditions of stasis hot applications are of much benefit. (3.) The wet pack is of value in chronic psoriasis, but is to be avoided if it tends to produce boils. (4.) Vapor and hot-air baths may be used as a means of treating syphilis, and possibly parasitic affections. (5.) Medicated water baths are soothing to a pruritic skin, and promote assimilation and disintegration. Carbonate of potassium, of sodium, and borax, one hundred and twenty, sixty, and thirty grammes of each respectively, with two hundred and fifty to five hundred grammes of starch in a barrel of water, makes a mild alkaline bath. (6.) Certain natural mineral springs have, of course, also their advantages; when there is a definite knowledge of what is to be accomplished they may be prescribed, like any other remedy, to fulfill definite indications. What is strong for good is strong for evil, however, and patients should not be sent to springs at random merely to get rid of them.

(To be concluded.)

T. M. ROTCH, M. D., SECRETARY.

APRIL 12, 1880. DR. JAMES C. WHITE, permanent chairman, president.

THORACENTESIS.

The regular paper for the evening was read by Dr. F. I. KNIGHT, on The Dangers of Thoracentesis and Injections into the Pleural Cavity.

Dr. Knight said that so many accidents following these operations were being reported on all sides that it became the friends of the operation to inquire into their exact nature, and how many of them were only such as might occur in the natural course of pleuritic effusion, and how many could properly be charged to the operation. Dr. Knight quoted reported cases showing various modes of death after thoracentesis and injections into the pleural cavity. Most of the cases could be grouped under the three heads. (1.) Embolism. (2.) Syncope (a) from paralysis of the heart; (b) from reflex action. (3.) Pulmonary edema.

Emboli are let loose by the expansion of the lung, and thoracentesis simply hastens the process, which would occur at all events when the lung expanded. Naturally, cases of embolism without operation were here quoted. So the knowledge of this process must not deter us from thoracentesis, but rather encourage us to operate early, before thrombi are formed.

Fatal or dangerous syncope and pulmonary edema have been due in some cases undoubtedly to the operation of thoracentesis. The convulsions which have occurred during injection into the pleural cavity have been attributed to embolism of the cerebral vessels or reflex action. Dr. Knight also called attention to some remarkable coincidences between tapping the chest and death from causes quite independent of the operation.

The dangers, therefore, against which we must be on our guard, in performing thoracentesis, are syncope and pulmonary edema, and a sufficient number of serious accidents have occurred to make us more careful in the operation.

(1.) Operate early, before thrombi are formed.

(2.) Operate in the recumbent posture to prevent cerebral anæmia.

(3.) Evacuate very slowly, and never remove large quantities at one sitting. Stop on the occurrence of the slightest distress.

(4.) Be very careful in removing fluid from the chest when the lung is diseased, or bound down by adhesions, and so incapable of expansion. Some of the worst accidents have happened in such cases.

Inasmuch as serious symptoms have attended injections into the pleural cavity in quite a large number of cases, it becomes us to use greater care in performing this operation. Dr. Knight thought that the use of syringes and pumps should be abandoned altogether, and the chest slowly irrigated by means of the douche, the reservoir being held only just high enough to secure a gentle current.

In regard to the treatment of accidents, when they have occurred, Dr. Knight said that if the trouble seemed pretty surely to be an overdistention of the

right heart, and death were imminent, puncture of the chest and admission of air might save the patient.

In case of edema of the lungs, venesection should certainly be considered.

Dr. H. I. BOWDITCH said that he had come to learn what dangers there were in thoracentesis. He had operated for thirty years (since April 17, 1850) 337 times, upon 226 patients, and he had never had any death, which in his opinion could be fairly said to be due to aspiration simple.

He had read of not a few deaths occurring in Europe after thoracentesis, but he had considered these fatal results to be owing to the folly and rashness of the operators themselves, or to the methods pursued. He denied that thoracentesis, *with injections into the chest*, should be used against the operation itself, whether simple aspiration were performed, or a permanent opening made by trocar or incision. But injections were now almost universally used in this country and in Europe, when a permanent opening was made. Dr. Bowditch attributed the fatality in these cases to the injection rather than to the operation. Without this hypothesis, he could not account for the fact that he had never met with cases, such as are reported in the paper just read.

Dr. Bowditch never used injections. [This is not strictly true, although in almost all the cases, under his own immediate charge, it is exact. He had consented, at times, to the use of injection, when called in consultation by other physicians, especially since carbolic acid has been brought into use. In his own cases he never allows any injection to be made, unless the pus becomes fetid, or, as in one case, where the patient was losing strength, and was apparently threatened with phthisis, from pus being retained in the pleura below the point of a permanent opening. In this case the simple washing out of the cavity with pure water, many years ago, and before carbolic acid was thought of, seemed to renovate the patient, and he recovered rapidly.]

Dr. Bowditch also thought that perhaps the reason why we, in this vicinity, had had no sudden fatal result, as recorded in Europe, notwithstanding that every physician here now operates, might be the fact that we have usually proceeded more cautiously than elsewhere. For himself, ever since he first began to operate, he had always deemed the part of prudence, and common sense, to *draw slowly* in aspiration, and with exceeding caution, *watching the effect upon the patient of every ounce drawn*. He usually said to the patient at the outset, "Tell me the first moment you feel a distress of any kind, especially any tightness across the chest." Dr. Bowditch was accustomed frequently to repeat the questions, "Do you feel comfortable?" "Have you pain?" "Can you breathe more easily?" "If you have any *stricture of the chest*, be sure to tell me so at once." And the moment that, on any such interrogatory, the patient answered in the affirmative, Dr. Bowditch removed the aspirator. He has done so many times, *even when he was sure that a very large quantity of fluid remained in the pleural cavity*. He had been induced to do so, because, in one or two instances among his earlier operations, he had caused an unpleasant, though never dangerous, dyspnea by *persisting in the operation, even for a short time*. Nature often seemed, however, in such cases, to say, "Take away a little fluid, and I will take care of the remainder."

Dr. Bowditch regarded aspiration as simple an operation as vaccination. He would as soon do one as the other, and because, occasionally, a patient died on the pricking of the skin, or even before the skin was touched, in aspiration, was no solid reason against the operation. Very rarely, a person may get syphilis or other disease, or may die after vaccination, but these rare results were no valid reasons for giving up vaccination. The question of a permanent opening and injections into the chest is a wholly different affair. Upon the question when, if ever, such permanent openings should be made, he must admit that he was in great doubt. Thirty years ago he opposed all permanent openings with the scalpel, as improper and barbarous operations. But he soon found that nature at times made them, and then he had to interfere in order to get the opening in a proper part of the chest. Two years ago he stated at the American Medical Association meeting that he was of opinion that, in adult cases, a permanent opening should be made after pus had been twice drawn. Recently, however, a case had been sent to him for counsel as to a further operation. Twenty-two aspirations of sero-purulent or purulent fluid had been drawn at very short intervals, generally every third day. Under this treatment the patient had gradually grown better, had gained flesh and strength. On examination, murmur was heard, without r le, throughout left breast, but less than at the right. Behind, was flatness on percussion in the lower two or three inches, and murmur was scarcely if at all heard there, and very quiet above. No other marked symptom or sign, except cough and some expectoration.

The question was asked: Shall a permanent opening be made into the chest to allow the small quantity of fluid, still remaining, to escape, upon the ground that nature will not remove it? Dr. Bowditch advised strongly not to make an opening of any kind. He saw no reason, *a priori*, why purulent absorption should not take place from the pleural cavity, as it does at times in other parts, and he hoped for that result in the case then presented to him. Some persons, however, assert that pus, if not removed by an operation, will always remain in the pleura. Is this a fact? Dr. Bowditch concluded by suggesting to the members of the society that hereafter, in some cases, the same treatment should be followed as in the one he had referred to, and that aspiration, every three days, should be performed for a month, in the hope that the lung, expanding, would gradually contract adhesions, as had evidently occurred in the case alluded to. Dr. Bowditch appealed to Dr. Ellis for an opinion as to the possibility of absorption of small quantities of pus from the pleura, under such circumstances.

Dr. ELLIS replied that he thought such absorption was possible, and probably quite often occurred. He also said that he did not understand how simple puncturing could prove fatal. In regard to syncope, that could be obviated by drawing the fluid off slowly, by the method first used by a German, and introduced at the Massachusetts General Hospital by Dr. Garland, making the fluid siphon itself from the chest. Dr. Ellis also remarked that a few meetings since he had stated his belief in repeated aspirations, thus keeping down the size of the cavity; and thus if a permanent opening has to be made it will be more likely to be successful. He instanced a case of a child in whom this treatment was successful. He

would aspirate every three days, if necessary; that is, as often as pus collected.

In reply to Dr. Bowditch, Dr. KNIGHT said that he was confident that great care had been used in the operation in some of the fatal cases of thoracentesis.

Dr. HALL CURTIS said that he had looked over the notes of sixty-nine aspirations, made by him during the past seven years, and once only was it followed by symptoms of distress; in this case half a pint of serum was withdrawn. The following night the patient was restless, with dysp ea and nervous agitation. The next day he remained in a stupid state with a temperature of 104.1  F. Seventeen days later he was discharged, relieved. "Respiration heard at both bases, accompanied with subcrepitant r les. General condition much improved."

Dr. FITZ stated that the result of the permanent retention of pus could hardly be regarded as different from that of fibrine, both being exposed to the same conditions. It was not a very rare occurrence to find encapsuled within the chest either cheesy, mortar-like, or greasy material, representing the results of a previous pleurisy. In such cases the appearances were not sufficiently characteristic to enable the observer to decide whether the original process were an empyema or a fibrinous pleurisy. With regard to the recommendation that thoracentesis should be performed while the patient was lying down, it would seem that if cerebral an mia were to be avoided this could better be done by operating with the patient in the upright position. The earlier and slighter symptoms could thus be more readily detected and relieved. If the patient were in the prone position the an mia would be likely to have reached a greater degree before prominent symptoms appeared.

PNEUMONIA; SUDDEN DEATH.

Dr. MINOT gave the following account of the case, which he had received from the attending physician, Dr. H. B. Wilbur, of Utica, N. Y. The patient was an unmarried lady, thirty-two years old. For a few days preceding Easter Sunday (March 27th) she complained of a cold, but kept about as usual till April 1st, when she took to her bed. The next day she was up and about the house, but in the afternoon she had a chill and severe pain in the right side. High fever followed, with delirium. April 5th there was evidence of hepatization of the lower part of the right lung. From this time she improved, and seemed convalescent, April 11th. She had had a good night, coughing but little. The pain was gone, and she took nourishment with relish. Pulse 88. Soon after the doctor left her, she got out of bed, for the first time, to make water. As soon as she got back into bed she became livid, then pale, asked for some drink, and died.

Dr. WHEELER thought that this case of Dr. Minot's was an unusual form of death for pneumonia. He had seen some patients die suddenly in this way, but the death was caused by an effusion into the pleura, and he would like to ask Dr. Minot whether death here might not have been caused in this way.

Dr. MINOT could not say, as he only had the report which Dr. Wilbur had sent to him.

Dr. ELLIS said that patients do die suddenly in this way from pneumonia, and that the symptoms as stated in this case pointed towards that disease.

Dr. STEEDMAN mentioned the case of a young man who had come into the hospital, during his term of

service, with fluid in the left chest, for which he was aspirated. A week or ten days later he was again aspirated, when he suddenly had a hæmoptysis, and died. There were no signs of aneurism. He did not know how much the thoracentesis had to do with the death, as he had never been able to give a satisfactory cause for the fatal issue of the case.

Dr. WHEELER said that he had lately seen a case where extreme dyspnea had occurred, and a latent pleuritic effusion not recognized before. Dr. Wheeler aspirated and found pus. He would ask Dr. Minor whether he thought a permanent opening was advisable in this case.

Dr. MINOR said that he thought it was.

Dr. BOWDITCH spoke in reference to permanent openings; they sometimes do badly, and the question is whether in some cases of empyema, instead of making a permanent opening as soon as pus appears, we should not make frequent aspirations, and instanced several cases in support of this, especially in children, where there is no need of making a permanent opening at first, as they may get well with aspiration.

Dr. BRADFORD showed a "club-foot stretcher," devised by Dr. T. G. Morton, of Philadelphia, to be used in old cases of club-foot, where tenotomy alone was not sufficient. Dr. Bradford had found the application of use in one case where he had tried it. The apparatus is described in the Surgical Report of the Pennsylvania Hospital.

Recent Literature.

The Hair: Its Growth, Care, Diseases, and Treatment.

By C. HENRI LEONARD, M. A., M. D., etc. Detroit: C. Henri Leonard, Medical Book Publisher. 1880.

We have here a small treatise of 312 pages, illustrated by 116 engravings. It is intended, evidently, for the laity quite as much as for the profession, and is meant merely as a forerunner of a future larger and more scientific work. The writer believes in the "possibility of the classification of animals from the differences in the microscopical structure of their hair shafts." And why not? In 1853 Dr. Holmes derided "ex pede Herculeum," and suggested the substitution of "ex ungue minimi digiti pedis, Herculeum, ejusque patrem, matrem, avos et proavos, filios, nepotes et pronepotes." And the world is still moving, though slowly.

We learn that London and Paris each consume annually over 100,000 pounds of human hair, a load for a train of twenty freight cars; that the hairs of a single average head would more than hold supported two hundred people, and could the covering scales be taken from the head hairs of the citizens of Chicago, and placed edgewise, they would make a footwalk over one hundred miles in length; that Absalom cut his hair once a year, shearing off six and one sixth pounds at a time; that an individual hair is finer in the negro than in the Caucasian, and in man than in woman; that blondes are disappearing from the Caucasian race, statistics showing also that hymenically a blonde stands three chances of failure to two chances on the part of a brunette; that, according to Pliny, the Persians counteracted the odors of their persons, due to dirt, by the use of perfumes [a method still in vogue amongst the laziest of the vulgar. — Rer.]; that the vocation of the wig-maker is rendered profitable by

close curling, crimping with hot irons, dyeing or bleaching, and uncleanness; that the prolonged use of facial cosmetics may cause death, as in the case of the late G. L. Fox [Humpty Dumpty]; that Edwin Smith, of Fairfield, Lenawee County, Mich., aged forty-five, had, when seen, a beard measuring seven feet in length; that Margaret, the Duchess of Parma in the time of Philip II., sported a long mustache; that the Cyprian Venus was represented with a beard, and the Athenian ladies, according to Suidas [tenth century], used to wear false beards when unsuccessful in raising what nature had denied them. In short, the book is a compilation of facts which may afford interesting reading for physicians or laity, and an unassuming treatise upon the diagnosis and treatment of diseases of the hair, the nomenclature and treatment being pretty well up to the times and though largely based upon, yet an improvement in some respects on, English views in regard to these matters. It is entertaining reading, suggestive, will prove of use to the general practitioner, and does credit to the energy and industry of its writer.

Students' Guide to the Diseases of Women. By A. L. GALABIN, M. D. Philadelphia: Lindsay and Blakiston. 1879.

From the condensed account of the Diseases of Women contained in this book, the author has omitted such subjects as extra-uterine fetation and retroversion of the pregnant uterus; also the description of several most important operations, as those for rupture of the perineum and for vesico-vaginal fistula.

For examining the interior of the uterus, preference is given to the sound, the objection offered to the probe passed through the speculum being that the "position of the uterus may be modified by the introduction of the speculum;" and yet the author virtually discards this objection in the very next sentence, when he says, "Moreover, the operator" — by using the probe — "thus sacrifices the great aid which the finger may sometimes afford in the case of flexion, by lifting up the fundus, and so partially straightening the uterus," — a procedure which modifies the position most materially. We feel sure that for delicacy of examination and accuracy of diagnosis the uterine probe is far superior to the sound.

The author's remarks on the Dangers from the Use of Tents, and Precautions Required, are the best which we remember to have seen. Among the causes of prolapse associated with elongation of the supra-vaginal cervix, we find one not commonly referred to, namely, when the cervix is already partially prolapsed, it is extruded through the vulva by any sudden effort, and is there gripped and partially strangulated, and its return prevented for a greater or less time, while the force of the elastic attachments above is constantly exerted to restore the organ to its normal position. We remember one case in our own practice which quite verifies this statement.

In speaking of the treatment of fibroids (sub-mucous) by enucleation, the author does not seem familiar with Emmet's method of removal by traction, and advises means which appear to us much more dangerous to the patient and annoying to the operator.

The volume contains twelve chapters, the arrangements of which are mostly based on their pathological bearings. For so small a work, the pathology of the subjects is well introduced.

Medical and Surgical Journal.

THURSDAY, APRIL 22, 1880.

A Journal of Medicine, Surgery, and Allied Sciences, published weekly by Houghton, Osgood and Company, Boston. Price, 15 cents a number: \$5 00 a year, including postage.

All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.

Remittances by mail should be sent by money-order, draft, or registered letter to Houghton, Osgood and Company, Boston, Mass.

HEALTH LEGISLATION AT WASHINGTON.

A BILL, which will be found elsewhere, has been introduced in the senate by Senator Harris, of Tennessee, to increase the efficiency of the National Board of Health. Some opposition has been manifested to the first section, especially, on the ground of its giving too much power to the board, and interfering with state, with local, and with individual rights. This section provides that the board, or, in the interval of its sessions, its executive committee, shall report to the president when any place in the United States is considered by it to be dangerously infected with contagious or infectious disease, and upon official publication by the president of such report the transportation of goods or persons from such place into another State shall be unlawful, unless carried on in accordance with rules and regulations made by the National Board of Health and approved by the president; and these rules shall apply until the president, having in the mean time received a weekly report from the board upon the sanitary condition of the place in question, shall proclaim it to be no longer dangerously infected. State susceptibilities are consulted in this section by the restriction of power to restraining transportation from one State to another, but one object undoubtedly is to offer to the various local authorities and petty boards of health, with crude and conflicting views and rules or none at all, a well-considered, intelligent, and uniform standard of principle and action, so that the intelligence of the towns will induce them to voluntarily adopt a policy toward each other, the beneficial effects of which they may see in operation between the States. The duty of a national board is not simply to control a system of quarantine, and to protect the country at large at certain critical periods from an invasion of an epidemic disease, but it has the much more important and constant duty — which the present organization deserves credit for bearing in mind as far as possible during its short and arduous existence — of advancing sanitary knowledge, of teaching the people in different parts of the country, and putting them in a position to protect themselves, both against the pestilence which comes from without and against the disease which is the result of their own ignorance. A board without authority and without appropriations can perform neither of these duties, nor does it command attention. The very parts of the country which witnessed the unnecessary cruelties and suffered from the disastrous obstructions of non-intercourse, enforced at times even by shot-guns in the hands of excited, unreasoning, irresponsible agents,

should be the first, and we believe they will not be the last, to appreciate the reasons for supporting this first section of the bill.

The board, moreover, desires to erect four complete quarantine establishments, — one near the mouth of Chesapeake Bay, one on the coast of Georgia, one on the Gulf coast of Mississippi, and one at Galveston, to which infected ships arriving at ports along the coast may be sent for cleansing and purification; the multiplication of petty stations would thus be dispensed with. For this purpose, and for making investigations into the causes and best means of preventing certain diseases and diffusing information on sanitary subjects, an appropriation of one hundred thousand dollars is asked, which will be needed in addition to the balance now on hand between now and June 30, 1881. The board also advises that an additional one hundred thousand dollars be appropriated, to be used, in the event of the appearance of yellow fever in the country, to aid state and local authorities in restraining the spread of the disease.

There seems to be some hesitation on the part of the committee on appropriations of the house of representatives about acceding to these demands, which we do not believe to be justified by the wishes and interests of their constituents. The sum demanded is not excessive for the purposes specified, and in view of the approach of summer, the existence of yellow fever in an active form at Rio Janeiro, and the work to be done, these objects are especially commendable. The money is certainly quite safe with the board, and a refusal to make the appropriation might, under certain circumstances, entail grave responsibilities.

MEDICAL NOTES.

— We regret to be obliged to announce the sudden death of Dr. Henry Clarke, of Worcester, on the 17th inst., from pneumonia. A graduate of Harvard in 1850, he has been a prominent practitioner in his own city for many years, and has been a highly esteemed and respected member of the Massachusetts Medical Society. He was much interested in the operation of ovariectomy, and in a very recent number of the *JOURNAL* reported several cases.

— Readers who notice in the *JOURNAL* for April 15th our request for opinions in regard to the usefulness of condensed milk as a food for infants will please include in their replies mention of the *kind*, or brand, of condensed milk they prefer, and their reasons for the preference.

— Javal, director of the Laboratory of Ophthalmology in Sorbonne, having made a study of the causes of fatigue in reading, concludes that, "other things being equal, the legibility of a printed page does not depend upon the height of the letters, but upon their breadth." Fatigue of the eyes he believes to be due to a permanent tension of accommodation.

— The *Union médicale* tells this story of what the *Medical Times* and *Gazette* truly terms "a colossal prescription." "A practitioner, who was called from Châlons to a neighboring commune, forgot his memo-

random book. When he had seen his patient he called for pencil and paper in order to write a prescription. This village, not having shared the benefits of a compulsory education, did not quickly furnish the desired implements. The doctor, tired of waiting, wrote his prescription on a barn door with some charcoal, and left. The relatives of the patient, being puzzled by the writing (which perhaps is not surprising), conceived the happy idea of unhinging the door and sending it to the apothecary. It duly arrived in a cart; the recipe was read from the pavement and duly dispensed."

— M. Palailon recently read before the Paris Academy of Sciences the results of his researches on the movements of the uterus. A registering apparatus and manometer were connected with the enlarging instrument sometimes introduced into that organ. The author calculated the specific force of the uterus to be about 178, and therefore very much below the force of striated muscles in man, which is about 1087. Uterine contraction produces a regular movement without shock, and is remarkable for its length, nearly two minutes (contraction and relaxation together, the former being the shorter). Violent respiratory movements raise the pressure considerably.

— Another medical student of the Hôpital des Enfants Malades, of Paris, has fallen a victim to diphtheria — the seventh student who has died of diphtheria contracted in this hospital. The *British Medical Journal* thinks these melancholy facts speak highly for the devotion of the young men, but probably also denote the unsanitary condition of French hospitals.

— In the Phipps Street Cemetery in Charlestown is the following inscription on a tombstone: —

Here lies Interred ye Body of Mrs. Elizabeth Phillips Wife to Mr. Eleazer Phillips Who was Born in Weitminter in Great Britain & Commissioned by John Lord Bishop of London in ye Year 1718 to ye Office of a Midwife & came to this Country in ye Year 1719 & by ye Blessing of God has Brought into this World above 3000 Children.

Died May 6th 1761. Aged 76 Years.

— We find the following in the *Canada Lancet*: "There is no telling what the ignorance, boldness, and complete self-possession of an impostor will do toward inspiring confidence among unthinking people; and there is no accounting for the mania with which people thirst after humbugs and deceptions. The truth is far too tame and uninteresting for many people; in order to be fascinated they must be fed on fiction."

— Ligatures made from the carbolized tendon of the kangaroo's tail are said to be of great value for tying vessels even of the largest calibre, being stronger, more durable, and far less liable to slip or break than the catgut ligature. Kangaroos are not so plentiful in this country as cats, but readers interested in the mode of preparing this new form of ligature will find details in the *Medical Times and Gazette* for March 13th.

— Dr. Vidal, *Progrès médical*, November 28, 1879, gives his reasons for asserting that in ulcer of the

stomach the patient commonly has a painful spot over the spinous process of the sixth dorsal vertebra, and in affections of the liver a painful spot at the spinous process of the fourth dorsal vertebra. In perityphlitis patients complain of a painful point at the junction of the second and third dorsal vertebra on the left side.

— In remarking upon a recent *concours* held in Chicago, the *British Medical Journal* says, "It is only in cities so 'organized' as Paris or so young as Chicago that a *concours* is required for the office of teacher and lecturer. In London, at least, students are kept well in their place; they *must* attend the lectures, and all the lectures, and none but the lecture nominated, or they will never get their certificates signed; and since the lecturer is sure of his class within moderate limits, whether he be audible or inaudible, whether he recite a text-book or indulge in the inordinate development of a taste for monologue or for crotchet, it is natural that there is in our London schools a large amount of inefficient lecturing, and much room for that stirring breath of reform which a system of *concours* would blow in upon the schools."

— M. Fournié has been led to conclude that the Eustachian tube is constantly open. The muscles attached, in his opinion, are not dilators, but constrictors, which close the tube during mastication and speaking. The renewal of air in the middle ear is produced by a sort of respiration, in which the constrictor muscles act as expirators.

— Dr. Purgesz, of Pesth, relates a case of poisoning by two and one half grains of sulphate of atropia, which recovered in three days under the use of a centigramme of muriate of pilocarpine every five or ten minutes, until sixteen centigrammes had been taken.

— The discussion of the merits of medical candidates for election to Parliament is a curious feature, just now, of English medical journals.

— The *Transactions of the Odontological Society of Great Britain* for March contains a photograph of a curious Hindoo bas-relief, representing a group of monkeys engaged in extracting a man's tooth. The unfortunate individual is bound, and the tooth is held in the grasp of a very primitive-looking extracting instrument (resembling somewhat the large claw of a crustacean), to which a small elephant is attached by means of tackles. The piece of sculpture was found in a ruined temple near Allahabad, known as the Stupa of Bharhut, and was more than two thousand years old, the temple having been built about the year 300 B. C.

— In the *British Medical Journal* Dr. W. Macfie Campbell writes: A case of stricture was admitted into hospital. There had been retention for some time, and no instrument could be passed. The aspirator was therefore used by the house surgeon with immediate relief. Next day, as catheterism again failed, aspiration was employed again. When I saw him on the following day I managed to pass a filiform bougie upon which a urethrotome was led, and the stricture divided internally. His progress was good for a day or two, when some inflammation appeared at one of

the aspirator punctures. An abscess formed, peritonitis came on, and the patient died. If aspiration has been performed, the bladder must be kept distended, as the fatal result was evidently due to the distended bladder, after the first aspiration, forcing some urine into the tissues. Tapping the bladder per rectum is much safer and altogether more satisfactory.

— News from Calcutta (*Lancet*, March 20th) states the probable appearance of beri-beri in that city. The disease, although familiar enough in Madras and Ceylon, does not appear to have been observed in Calcutta before. The symptoms as described are swelling of limbs, fever, occasional disturbance of the bowels, often burning and pain in the affected limbs, shortness of breathing, and great emaciation in fatal cases. Death is generally sudden. Showing itself first in the southern part of the city, the disease has gradually spread to the northern. Hitherto Europeans have escaped the malady, the natives, Circassians, and Armenians alone having suffered; and this notwithstanding that the disease chiefly prevails in the European quarter. Whole families have been seized, and its "localization" is said to be pronounced. The malady is reported to be dying out, but its reappearance in the rainy season is anticipated.

— The College of Physicians and Surgeons offers a prize for 1881 of \$500, for any subject in medicine or surgery. The alumni of the college alone are allowed to compete. We believe this is the largest medical prize offered in this country. A similar prize will be given in 1882.

— Dr. Edward T. Williams, physician of the Sea Shore Home, at Winthrop, in submitting the fifth annual report of the Home, states that the house was opened on the 3d of July and closed on the 9th of September, a period of sixty-nine days. The whole number of inmates was two hundred and eighty-five. Their ages were as follow:—

Under three months.....	2
Between three and six months.....	10
Between six months and one year.....	22
Between one and two years.....	34
Between two and three years.....	17
Between three and five years.....	38
Between five and ten years.....	48
Between ten and fifteen years.....	19
Between fifteen and twenty years.....	4
Over twenty years.....	91

The whole number of children, therefore, or persons under twenty years of age, was one hundred and ninety-four. The diseases of these children were as follows:—

Cholera infantum.....	21
Dysentery.....	3
Diarrhoea.....	63
Simple debility.....	35
Other diseases.....	72
Total.....	194

There were but two deaths, one from cholera infantum and one from convulsions.

— The waterproof paper originated by Dr. W. W. Keen, of Philadelphia, is sold under the name of "Mead's Surgical Dressing Paper." Dr. Jones, ex-president of the Ohio Medical Society, says of it,

"This paper provides an excellent substitute for oiled silk or rubber tissue at a trifling cost as compared with these articles. Besides its use in surgery, the ordinary practitioner of medicine can make this paper available as a covering for wet applications (either general or local), and give his patient the benefit of a continuous bath when desirable, with a trifling amount of trouble and cost. Dr. Keen is entitled to the gratitude of the profession and our patients." In a former allusion to this paper we mentioned the cost of it as being four cents per yard. We should have said that except in large quantities the selling price is seven cents the yard.

— The *Louisville Medical News* says, "A cross-grained Boston doctor claims that the faculty of Harvard Medical College is composed of men who are either 'effete reminiscences of other days, or the mere accidental appointees of a system of disgraceful wire-pulling.'"

— In an editorial on Pay Hospitals, suggested by Mr. Burdett's book on that subject, the *New York Medical Record* refers approvingly to the Carney Hospital, at South Boston. The advantages of this institution have undoubtedly been appreciated by the public, of late years; but as it shelters many sick and infirm people who pay little or nothing, and as to all this large class the services of the staff are still entirely gratuitous, more ample funds would enable this hospital to do greater justice to the demands made upon it. The management and nursing are, moreover, in the hands of Sisters of the Roman Catholic Church, so that its expenses are reduced to a minimum.

— "Some time ago," says the *Pacific Medical and Surgical Journal*, "we mentioned the fact of the County Hospital at Sacramento being placed in the hands of the homœopaths. Among the drugs used by them and paid for by the city, according to the published statement of Dr. Tyrell, were fourteen hundred and fifty two-grain quinine pills and three pounds of salicylic acid supplied by one druggist, and three hundred two-grain quinine pills, one ounce of quinine, and a considerable quantity of morphia by another. In fact, the medicine bill was so high that from this cause, in part, the authorities removed the homœopathic doctor, and appointed a 'regular.' It is time for homœopaths to throw off the mask with which they have been deceiving the public, and to make an honest confession that they cannot cure disease without resorting to the regular system."

— Dr. Wm. Strew, of New York city, has brought suit against the *Herald and Telegram* for fifty thousand dollars. He claims that he lost his position as medical superintendent of the insane asylum on Blackwell's Island through false publications in those papers.

— Cincinnati has four bogus medical colleges engaged in manufacturing diplomas. The names of these institutions are the Physio-Eclectic Medical College, the Physio-Medical College, the American Eclectic College, and the American Vitopathic College.

— Efforts are being made to pass a bill in the Ohio legislature "for the establishment of a board of health and the regulation of the practice of medicine."

—It is stated upon the authority of Mr. Lewis, a nephew of General Washington, that Dr. James Craik, his family physician, was the only man between whom and Washington there had always been entire unreserve and confidence.

PROVIDENCE.

—At a recent meeting of the Rhode Island Homœopathic Hospital Aid Association, a committee was appointed to memorialize the city council of the city of Providence and the General Assembly of the State, for the purpose of securing from the former a portion of the amount annually appropriated for the medical treatment of the city poor, and from the latter the privilege of locating a homœopathic dispensary within the buildings of the Rhode Island Hospital. The amount of the appropriation for the sick poor of the city is six hundred dollars per year, which sum is placed in the hands of the overseer of the poor, an officer elected by popular vote, to be applied in whatever manner he may think best. He has divided the city into three districts, and appointed a regular physician for each. These physicians are required to furnish medicines as well as advice to the patients under their care. Applicants for medical aid must first obtain an order from the overseer of the poor, and the fact that this officer has held his present position for seventeen years, and is personally acquainted with the circumstances of nearly every poor family in the city, is a sufficient guaranty against any abuse of this charity. Thus the whole matter is under his exclusive control, and is entirely independent of any action of the city council. The Rhode Island Hospital is an institution founded and supported wholly by private benevolence. It is governed by a board of trustees, elected annually by the corporation. Neither the city nor the State contributes anything to its support, nor holds any control over its management. In view of all these facts it is not at all probable that the action of the homœopaths will be attended by such satisfactory results as were anticipated by the initiators of the movement.

NEW YORK.

—The whole profession sympathizes very deeply with Professors Sayre and Loomis in their recent sad bereavements. The eldest child of the former, Dr. Charles Henry Hall Sayre, died on the 11th, and the wife of the latter on the 14th, of April. The death of young Dr. Sayre was due to secondary hæmorrhage following a very severe compound comminuted fracture of the femur, which he received by a fall of twenty feet into the basement area of the Gilsey House, six days previously. Drs. Markoe, Wood, and other well-known surgeons were in attendance, but the amount of blood lost was so great that collapse ensued before the hæmorrhage could be effectually controlled. The autopsy showed that there was very extensive sloughing of the tissues, and that the fatal hæmorrhage was due to an orifice in the walls of the *profunda femoris*, which was probably perforated by a spicula of bone at the time of the accident. After the fracture the fragments protruded to such an extent that it was

necessary to saw off their ends before they could be replaced. By long association with his illustrious father, Dr. Sayre had acquired remarkable skill in those departments to which his practice was principally confined, and his warm-hearted, generous, and impulsive nature had won him hosts of devoted friends in every circle of society. At the time the injury was received he was engaged, on behalf of the finance committee of the American Medical Association, in soliciting subscriptions towards defraying the expenses of the coming meeting of the association from some of the principal hotel proprietors of the city.

The funeral services were held at the house of Professor Sayre on the 14th, and so great was the attendance that large numbers of friends were obliged to go away without being able to gain admission. An eloquent eulogy was pronounced by the Rev. Dr. William Ormiston, an intimate friend of the family, and the body was then interred in the family vault at St. Andrew's Church in Harlem. Mrs. Sayre's father was the former owner of the land on which St. Andrew's stands, and he presented it to the church, reserving, however, a burial lot for the use of his descendants. After the funeral the floral offerings, which were very numerous and beautiful, were sent by Professor and Mrs. Sayre to be distributed among the patients at Bellevue Hospital.

—Dr. Henri Wachtel, who has been engaged for some months in organizing for New York a system of night medical service such as exists in Paris and other European cities, has finally perfected his scheme. A petition and bill have been sent to Albany. Senator Strahan agreed to introduce the bill, providing the scheme received the approval of the faculty. Dr. Wachtel procured without difficulty the signatures of most of the best known medical men in the city to the petition. Among them are Fordyce Barker, Thomas Van Buren, E. D. Keyes, George F. Shady, Austin Flint, Isaac Taylor, J. Marion Sims, Alfred C. Post, E. C. Seguin, Austin Flint, Jr., H. B. Sands, Alfred L. Loomis, and William A. Hammond.

The bill is modeled upon the French statute, and is entitled "An act to organize a night medical service in the city of New York, and to provide medical assistance in cases of sudden sickness or accident during the night-time." In the bill it is provided that the captain of each police precinct shall keep a list of physicians in good standing who may present their names. Upon application of any person, the physician living nearest to the house of the patient is to be informed by the police of the application and conducted to the proper place. A careful statistical record is to be kept of all cases, the names and addresses of the patients being always suppressed. In case the patient is not able to pay, the visiting physician is entitled to receive a fee of \$3 from the public treasury, on presentation of a certificate indorsed by the captain of the precinct in which the visit was made. Police captains may also cause the list of physicians to be posted in hotels and district telegraph offices. The bill further provides for the annual appropriation of \$2000, for the support of the service.

PHILADELPHIA.

— At the last meeting of the College of Physicians, Professor Da Costa reported three cases, occurring in one family, of death from what he termed "starvation fever," for want of a more distinctive title. The cause appeared to be very clearly due to imperfect or insufficient nutrition, and they presented many of the characteristics of cerebro-spinal fever; although no lesions, beyond marked paleness of the mucous lining of the intestinal canal, were observed. At the same meeting, Professor Henry C. Chapman read an obituary address upon the late Professor Meigs.

— A very convenient method of testing urine for sugar has been recently made available, which is far superior to any of the test solutions now in use. Dr. Pavy proposed (January 23, 1880) to the Clinical Society of London the use of "cupric test pellets" (of solid Fehling's solution), which are to be dissolved in water at the time of examination of the urine. At the suggestion of Dr. Jos. S. Neff, of this city, Mr. McKelway, one of our leading druggists, has prepared these pellets in the form of compressed pills. As they are made of a definite weight, they can be used not only for qualitative but also for quantitative analysis; each pellet representing one cubic centimetre of Fehling's test, and each, when dissolved in distilled water, being reduced by five milligrammes of glucose. In view of the instability of Fehling's test solution, the method here described has much to commend it. (See *Phila. Med. and Surg. Rep.*, April 10, 1880, for original article of Dr. Neff.)

— Dr. J. Solis Cohen has been using oxygen inhalations after tracheotomy for croup, with good temporary results.

— There has been a mild epidemic of measles in progress in this city for several months, but within a very short period the cases have rapidly increased. Small-pox continues to give about one death per week, but has not at any time this winter reached the proportions of an epidemic. Diphtheria is quite prevalent; and so is typhoid fever, although to a less extent. The president of the Philadelphia County Medical Society, Dr. Albert H. Smith, is seriously sick with typhoid.

— The thirty-first annual session of the Pennsylvania State Medical Society will be held at Altoona, on Wednesday, May 19, 1880. Dr. Andrew Nebinger is president of the society, and Dr. John Fay, of Altoona, chairman of the committee of arrangements. A large and interesting meeting is anticipated.

WASHINGTON.

— The United States senate has at last passed a resolution legalizing the health ordinances and regulations for the District of Columbia; but of course it had to be debated, and one vote, at least, was cast against it for the expressed reason that, among other things, it was too arbitrary in declaring the ailanthus-tree a nuisance injurious to health.

— On April 14th a memorial was introduced in the house of representatives from the State Board of Health of Mississippi, to the effect that the National

Board of Health has promptly extended during the past year all the aid needed to protect the State against another epidemic visitation of yellow fever, and expressing in the most emphatic manner the opinion that the affairs of the National Board of Health have been administered with great prudence and ability; viewing with a feeling of great concern the indications of a prejudiced hostility to the National Board of Health, which have been manifested in certain quarters, and urging the senators and representatives of Mississippi in the Congress of the United States to support the National Board in its laudable efforts to carry out the great work imposed upon it; and declaring, finally, "that we cannot efficiently discharge our duty without the aid and coöperation of the National Board of Health, and that any action on the part of Congress tending to restrict the power, or to withhold the means needed to carry out the recommendations made in connection with the National Academy of Sciences by the National Board of Health in its annual report, would be regarded by us as a direct blow at the most vital interests of our beloved State."

Miscellany.

FATAL USE OF THE ASPIRATOR.

MR. EDITOR.—Hall C. Wyman, of Detroit, in volume vii. of the Transactions of the State Medical Society of Michigan for 1879, has an important and interesting paper, describing a case of Fatal Use of the Aspirator, and Experiments on the Introduction of Air into the Veins, which should, I think, be published in every medical journal in the country. Meantime, the aspirator having been a favorite with us, and in daily use by the profession at this time, allow me through the JOURNAL to call attention to the article that a possible repetition of the misadventure may perhaps be avoided.

In the case reported, aspiration some three months before, for the removal of a quantity of pus from the pelvis, had been followed by much relief. The symptoms having returned, the needle was again introduced through the vagina to the left of the uterus, a distance of three fourths of an inch. As soon as the pumping was commenced the patient manifested pain, became convulsed, and grew purple. Congestion of all the superficial veins followed, though the needle was immediately withdrawn as soon as the symptoms began, when no more than four or five strokes had been made. In three minutes the patient was comatose, and in ten minutes the heart ceased to pulsate.

"The autopsy revealed a small punctured wound on the left side of the vagina, one and a half inches before its juncture with the uterus. The probe passed upward and to the left three fourths of an inch in the direction of a soft tumor in the uterus. Around the track followed by the probe was no more than a teaspoonful of clotted blood. A close network of small veins was traversed by the puncture just outside of the vagina, but after the most diligent search it was seen that no important blood-vessel had been touched. The areolar tissue about the uterus contained air. The left lung was much congested. The right chambers of the heart were filled with air, and contained no blood. The left chambers were empty. The valves were nor-

mal. The veins of the stomach were distended with air, presenting the appearance of pale round worms," etc.

The above-described amount of air found in the vessels and tissues can be explained only on the supposition that the valves of the aspirator were accidentally set for condensation instead of aspiration; or that they worked imperfectly from want of care or other cause; or that *when the instrument is in perfect order and the needle introduced the working of the piston may carry or admit into the tissues air enough to cause death, although insufficient to work its valves regularly.* Experience has shown, apparently, that for the entrance of air into the venous system its contact with an open vein or veins situated near the heart or interiorly was necessary. The alternate contractions and dilatations of the right heart tend constantly to draw the contents of the venous system into its chambers, and thus under certain circumstances to facilitate the rapid entrance of air into the circulation.

If one death has occurred from the admission of air into the veins through the aspirator, what shall be done to prevent further accidents of the kind? Dr. Wyman says, "Aspirators should be provided with a check valve at the mouth of the tube which communicates with the needle;" but we already have one check valve between the pump and the receiver to stop the entrance of air towards the body on the descent of the piston. If this at times has been found ineffectual, will it do to trust another instrument of the same kind?

My method of making an exploratory puncture has been first to exhaust the receiver as perfectly as possible, close the stop cocks, introduce the needle, and open the stop-cock connecting it with the receiver; and if no discharge appears after proper manipulation of the needle any additional "pumping" would, I think, be at least useless, and, as we have seen, might result fatally. As a precaution against the possible absorption of the air contained in the needle tube communication with the receiver should be opened as soon as the needle has penetrated the skin. When the expected discharge flows but slowly the vacuum can be removed, safely I think, by more or less pumping, as found necessary, or the stop-cock connecting the needle with the receiver may be closed, if preferred.

With these precautions against the introduction of air by the aspirator, we believe no fatal results can occur from that cause.

S. PUTNAM, M. D.

MONTPELIER, VT., April 13, 1880.

THE PLACENTAL SITE.

MR. EDITOR.—In your first number of the present year, page 9, under the head of Recent Progress in Obstetrics, your collaborator speaks of a peculiar condition of the uterus at the site of the placenta which had been observed by Dr. Roper, of London; a footnote refers to the London *Lancet* for October 25, 1879. I had made the same observation more than two years before, which observation was not published, however, till February, 1879. If you will have the kindness to refer to page 175 of the February (1879) number of the Chicago *Journal and Examiner* (one of your exchanges, I believe), you will see that I spoke of this peculiar condition of the uterine tissue at the placental site at the meeting of the Chicago Gynaecological So-

ciety, held December 27, 1878, nearly a year before Dr. Roper's observation in the *Lancet*.

I wrote this gentleman upon the subject, and also sent him a reprint containing my remarks. In reply I received a letter courteously allowing the evidence of my priority in this matter (which I beg you to regard not too trivial), and I should feel obliged if you would call it to the attention of your readers.

EDWARD WARREN SAWYER.

CHICAGO, April 14, 1880.

A BILL TO INCREASE THE EFFICIENCY OF THE NATIONAL BOARD OF HEALTH.

Be it enacted by the senate and house of representatives of the United States of America in Congress assembled, That the National Board of Health, or, in the interval of its sessions, its executive committee, as hereinafter provided, shall report to the president of the United States when any place in the United States is considered by it to be dangerously infected with contagious or infectious disease; and that upon official publication, by the president, of such report, the transportation of goods or persons from such place into another State shall be unlawful, and all persons guilty thereof shall be liable to prosecution therefor in the circuit or district court of the United States for any district within which such goods or persons shall be transported; and any goods so transported shall be liable to be seized and destroyed, unless such transportation shall be carried on in accordance with rules and regulations made by the National Board of Health and approved by the president, as in other cases. These rules shall apply until the president shall proclaim such place no longer dangerously infected, and in the mean time the board, or its executive committee, shall report to him weekly, in writing, the sanitary condition of the place in question.

Sec. 2. That the commanding officers of all merchant vessels entering any port of the United States from any foreign port or ports situated between the parallels of thirty degrees south latitude and forty degrees north latitude, or upon the Mediterranean Sea, shall, upon demand therefor, produce and deliver to the customs officer of the port of entry a bill or bills of health for such vessel, signed by the consul, vice-consul, or other consular officer of the United States at such port or ports of departure, or from the medical officer at such port or ports, where one has been appointed or detailed for that purpose (such bill or bills to be in accordance with the forms and regulations prepared for that purpose by the board and approved by the president), and in case of non-compliance therewith they shall be liable to the penalties provided by Section 1 of the "Act to prevent the introduction of contagious and infectious diseases into the United States," approved June 2, 1879; that the collectors of customs shall forward monthly to the National Board of Health, through the secretary of the treasury, the bills of health delivered to them during the preceding month by vessels from either foreign or domestic ports, or copies thereof duly certified.

Sec. 3. That whenever, upon an application by the board for a detail of a medical officer as provided in Section 2 of the "Act to prevent the introduction of contagious and infectious diseases into the United States," approved June 2, 1879, it shall appear to the

president that such detail cannot conveniently be made, and such decision shall be communicated by him to such board, the board shall be authorized to appoint such medical officer at its discretion, and, if so appointed, his salary shall be paid out of the appropriation under its control.

Sec. 4. That the board is authorized to confer, from time to time, upon an executive committee, consisting of not less than five of its members, such powers and duties as it may deem advisable, but any such extraordinary delegation of powers shall be in force only until the next meeting of the board, and thereupon shall cease unless renewed.

Sec. 5. That the board is authorized to print its annual report for the year ending December 31, 1879, with the appended documents, and to have the necessary illustrations prepared for the same, at a cost not to exceed eight thousand dollars.

ELASTIC LIGATURE FOR THE CORD.

MR. EDITOR, — The *American Journal of Medical Sciences*, page 567, says that "Dr. P. Budin, of Paris, uses a caution thread to ligature the funis, if bleeding is feared." For years I have used india-rubber bands, for sale anywhere at stationers for this purpose. Put around twice or more times, according to the size of the cord. It tightens as Wharton's jelly issues, and the cord becomes smaller. JAMES O. WHITNEY.

PAWTUCKET, R. I.

SALE OF DIPLOMAS.

DEPARTMENT OF THE INTERIOR,
BUREAU OF EDUCATION,
WASHINGTON, D. C. March 26, 1880.

DEAR SIR, — I have the honor to invite your attention to the following important letter from the United States Minister at Berlin of the 2d ultimo, and to the communication from the Honorable the Secretary of State transmitting the same to the Honorable the Secretary of the Interior, by whom the paper was referred to me.

The issue of fraudulent diplomas by so-called institutions of learning in our country has been brought in many ways, and often, to the attention of this office; the institution named in Mr. White's letter is not the only one of this kind known here.

The accompanying data bring on the character of these disgraceful transactions quite unmistakably. After reading them, I trust that you will cooperate in the detection of the offenders and the prevention of a practice so injurious to the credit of learning in the United States, and so opposed to the laws and practices of other nations.

Very respectfully, your obedient servant,
JOHN EATON, Commissioner.

MR. EVARTS TO MR. SCHURZ.

DEPARTMENT OF STATE,
WASHINGTON, March 12, 1880.

SIR, — I have the honor to transmit herewith for your information a copy of a dispatch (No. 87) of the 2d ultimo, from Mr. White, the Minister of the United States at Berlin, in relation to spurious diplomas issued by a so-called American University at Philadelphia. I beg to express the hope that it will be found practicable to devise measures, through the Bureau of Education or otherwise, for the effectual suppression of the practice of issuing spurious diplomas at Philadelphia, which is proving so injurious to the reputation of this country with respect to higher education.

I have the honor to be, sir, your obedient servant,
WM. M. EVARTS.

The Honorable CARL SCHURZ, Secretary of the Interior.

MR. WHITE TO MR. EVARTS.

LEGATION OF THE UNITED STATES,
BERLIN, February 2, 1880.

SIR, — I regret to state that there seems to be a revival here of the sale of diplomas purporting to be issued by an institution of learning in the United States.

Some weeks since a Mr. Pappenheim brought me a diploma, engrossed on parchment in very handsome style, and issued nominally by "the American University at Philadelphia," conferring the degree of doctor of medicine upon one Christopher Schuetz, living, as I understand it, at Leipzig. It would appear that the diploma was offered to Schuetz upon condition of his paying a sum of money for it. It bears the signatures of a number of persons claiming to be professors in the aforesaid university, at the head of them being the signature of "John Buchanan, M. D." Schuetz desired the Legation to give him a declaration of its genuineness and value, which I refused to do. One peculiar feature of the diploma was that, although evidently entirely new and recently issued, it was dated 1872.

About ten days since another and more serious case was brought to my notice. The judicial authorities at Prenzlau forwarded a copy (which I inclose) of a diploma issued by the same alleged institution to Paul Christoph Erdmann Volland, and signed by a faculty at the head of which appeared the same name of "John Buchanan, M. D." The authorities at Prenzlau asked the Legation regarding the genuineness of the diploma and the standing of the institution, it being with them a question whether Volland could be allowed to practice his profession under such a diploma.

After looking through the correspondence on record in this Legation (a memorandum of which is inclosed), and seeking in vain for the name of the institution in the list of colleges and universities published by the Bureau of Education in the Department of the Interior, at Washington, my answer was unfavorable to Volland's claim.

From the correspondence above referred to, I find that attempts have been made by the legislature of Pennsylvania for the suppression of this nuisance; but that, after all, it is a question whether these attempts have been successful, and whether the institution has not still a legal existence. This being the case, I would respectfully suggest that the matter be brought to the notice of the Commissioner of Education in the Department of the Interior, at Washington, and that he forward me any documents or information in his possession regarding the subject.

You will observe among the papers accompanying the diploma of Volland something much more serious than the diploma itself, and that is the authentication of it by Philip A. Cregar or Gregar, notary public of Philadelphia; and I bring this matter especially to the notice of the Department hoping that something may be done to prevent officials in Pennsylvania lending themselves to what undoubtedly is a fraud, whether under the forms of law or not.

That such cases as these have brought disgrace upon the American system of advanced education and upon the American name in general is certain. This has been recently revealed to me incidentally in a curious way: in a very successful play now running at the Royal Theatre in this city, a play written, strangely enough, by a judge of one of the highest tribunals in the empire, one of the characters, in casting a reflection upon another who is dignified with the title of doctor, declares a belief that the latter had simply bought his degree in America; and in a recent novel, by a popular author here, the scoundrel of the book, having escaped justice in Germany, goes to America, and is at last advised very comfortably settled, and practicing medicine with a sham diploma which he has bought for money.

All this, of course, is of no especial significance in this case, save as it shows that the fair fame of our country has been and can be injured in the mind of a large number of people even by such contemptible transactions as those herein referred to.

I have the honor to be, sir, your obedient servant,

AND. D. WHITE.

The Hon. WILLIAM M. EVARTS, Secretary of State, etc.

THE DIPLOMA OF VOLLAND.¹

Omnibus ad quos littere presentes pervenerint, praeses, censeat, professoresque Universitatis Americanae Philadelphiae, Republicae Pennsylvaniae legibus constituit, salutem.

Quum in omnibus academiis rebus legitime constitutis, aut hic auctoritate gentium, usus laudabilis et antiquus fuerit, ut viri, qui vel litteris vel artibus ingenius, vel quibuslibet studiis liberalibus, non minus diligenter quam felicitate operam dederunt, interea recte atque honeste se gerentes, aliquo eximio honore adornarentur, et ad meritam dignitatem attollerentur, et quum nos, secundum leges republicae nostrae, ampliusnam potestatem insigniendi decorandique titulis academicis, et promovendi ad gradus in sacra theologia, legibus, artibus liberalibus ac medicinis viros bene merentes tenemus, nos igitur, hac auctoritate praefati, usque antiquum laudem immemores, decrevimus virom egregium, studiosi optimis delectum, Paul Christoph Erdmann

¹ The diploma as given here is an exact copy of the original; the words written in the blank form are indicated by the use of italics.

Volland, de enjus eruditione in chirurgia dentaria arte et probis moribus satis compertum exploratorio habemus, dignum atque idoneum qui honoretur, ut vir doctus altissimo dignitatis gradu; quare non animo et creavimus et teximus enim chirurgia dentaria docetur, eique omnia jura et privilegia quæ ad illum gradum attinent delinimus et concessimus.

In quorendi idem, has literas signo magno universitatis literarum nostræ communiri jussimus, hoc decimumquarto die mensis Octobris annoque Domini nostri millesimo octingentesimo septuagesimo nono.

JOHN BUCHANAN, M. D.; JOHN J. FULMER, M. D.; ROBT. DEBESTE, M. D.; RICHARD FORBES, M. D.; CHARLES G. POLE, M. D.; C. H. KEHRROTH, M. D.; JAMES COCHRAN, M. D.; J. K. BOWERS, M. D.

SEAL: { Eclectic Medical College
& American University, }
Philadelphia, 1850.

A. P. BISSELL, LL. D.; JAMES ROBINSON.

THE NOTARY'S CERTIFICATE.

I, Philip A. Cregar, a notary public for the commonwealth of Pennsylvania, residing in the city of Philadelphia, do hereby

certify that the diploma hereto annexed from the "American University of Philadelphia" is the regular diploma of that institution; that the university is a regularly incorporated institution in good standing, and that the signatures on said diploma are genuine, and were acknowledged before me in due form of law.

Witness my hand and notarial seal this fourteenth day of October A. D. 1879.

PHILIP A. CREGAR,
Notary Public.

CERTIFICATE OF THE PROTHONOTARY.

STATE OF PENNSYLVANIA, County of Philadelphia, ss:

I, William B. Mann, prothonotary of the courts of common pleas of the county of Philadelphia, do hereby certify that Philip A. Cregar, Esquire, by whom the annexed certificate was made, was at the time of so doing, and now is, a notary public in and for said county, duly authorized to take acknowledgments and administer oaths, etc., and that I am well acquainted with the handwriting of the said Philip A. Cregar, notary public, and verily believe the signature thereto is genuine.

In witness whereof I have hereto set my hand and affixed the seal of the said courts this sixteenth day of October, 1879.

WILLIAM B. MANN, Prothonotary.

Two thousand six hundred and sixty-one deaths were reported; 1043 under five years of age; principal "zymotic" diseases (small-pox, measles, diphtheria and croup, diarrheal diseases, whooping-cough, erysipelas, and fevers) 430, lung diseases 412, consumption 393, diphtheria and croup 139, scarlet fever 68, measles 54, typhoid fever 48, whooping-cough 32, diarrheal diseases 31, erysipelas 23, malarial fevers 19, cerebro-spinal meningitis 15, small-pox one. From measles, New York 12, Philadelphia 11, Chicago eight, Brooklyn seven, New Orleans and Pittsburgh four, St. Louis and New Haven two, Mil-

waukee, Lowell, Malden, and Palmer one. From whooping-cough, New York, District of Columbia, and Pittsburgh four, Cleveland three, St. Louis, Boston, Cincinnati, New Orleans, and Buffalo two, Philadelphia, Brooklyn, Chicago, New Haven, Nashville, Gloucester, and Bridgewater one. From erysipelas, New York five, Brooklyn three, Philadelphia and Baltimore two, New Orleans, District of Columbia, Cleveland, Pittsburgh, Milwaukee, Providence, Lowell, Chelsea, Taunton, Beverly, and Plymouth one. From malarial fevers, New York seven, Brooklyn four, St. Louis three, New Orleans two, Chicago, Baltimore,

and New Haven one. From *cerebro-spinal meningitis*, Worcester three, New York, Philadelphia, and Chicago two, Cincinnati, Pittsburgh, Milwaukee, Chelsea, Fitchburg, and Brockton one. From *small-pox*, Chicago one.

One hundred and eleven cases of measles, 37 of diphtheria, 17 of scarlet fever, two of whooping-cough, and one of typhoid fever were reported in Brooklyn; diphtheria 22, scarlet fever six, in Boston; diphtheria 12, scarlet fever six, in Milwaukee; scarlet fever 29, diphtheria eight, typhoid fever two, erysipelas one, in Providence; typhoid fever two, scarlet fever one, diphtheria one, in Cambridge; scarlet fever three, in New Bedford.

The total number of deaths reported was about the same as for the previous week; the deaths under five slightly increased. Lung diseases showed an increased mortality, pulmonary consumption somewhat diminished. Typhoid fever continues to prevail in Pittsburgh. Scarlet fever continues to decline in Providence and Cleveland; measles, diphtheria, malarial fevers, declining; diphtheria slightly increased. In 37 cities and towns of Massachusetts, with an estimated population of 986,410 (pop-

ulation of the State about 1,690,000), the total death-rate was 22.89 against 20.89 and 21.96 of the previous two weeks.

For the week ending March 20th, in 148 German cities and towns, with an estimated population of 7,668,125, the death-rate was 27.6 against 26.9 and 28.2 of the previous two weeks. Five thousand six hundred and forty-five deaths were reported; 1954 under five; pulmonary consumption 696, acute diseases of the respiratory organs 506, diphtheria and croup 129, typhoid fever 72, whooping-cough 70, measles and *rötheln* 61, scarlet fever 59, puerperal fever 21, small-pox (Königsbush, Beuthen, Freiberg) four, typhus fever (Königsberg, Posen) two. The death-rates ranged from 17 in Darmstadt to 42.3 in Augsburg; Königsberg 34.9; Breslau 34.7; München 36; Dresden 28.4; Berlin 25.1; Leipzig 19.7; Hamburg 29.1; Hannover 21; Bremen 23.8; Cologne 24.9; Frankfurt 23.6. For the same week, Vienna 34.6, — small-pox still prevalent, also measles and scarlet fever; diphtheria declining; Paris 32.9; London 20.9. The meteorological record for the week in Boston was as follows:—

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U. S. ARMY, FROM APRIL 10, 1880. TO APRIL 16, 1880.

HORTON, S. M., major and surgeon. Assigned to duty as post surgeon, Fort Douglas, Utah Territory. S. O. 39, Department of the Platte, April 6, 1880.

COLLEGE OF PHARMACY.—The exercises of the twelfth commencement of the Massachusetts College of Pharmacy occurred in Union Hall. The roll of the class was as follows: Ida Rebecca Brigham, M. D., John Walter Bachelder, James Sylvester Barry, George Richard Bell, Charles Andrew Boyden, Franklin Edward Boyden, Joseph Allen Chapin, George Sumner Churchill, Frank Clough, Charles Louis Curtis, William Henry Cutting, Azro Milton Dows, Eugene Hamblet, Frederick Albert Jewett, James M. Kerrigan, Elie Henry La Pierre, Charles James Peters, Alfred Pillsbury, Jr., George Henry Sanderson, William Edward Turple. A certificate of proficiency was presented to Dr. Brigham, and the degree of Graduate in Pharmacy was conferred upon the members of the class by President B. F. Stacey, who also made a brief address of instruction. The valedictory on behalf of the class was delivered by Mr. J. A. Chapin; the address for the Faculty by Prof. E. L. Patch, Ph. G. Subsequently the faculty tendered a reception to the graduates of the class of 1880.

SUFFOLK DISTRICT MEDICAL SOCIETY.—The annual meeting will be held at the hall, No. 19 Boylston Place, on Saturday evening, April 24th, at seven and a half o'clock. Reports of committees. Election of officers at 8.30 p. m. The following papers will be read: Dr. F. H. Williams, A Simple Method of determining the Amount of Urea in the Urine. Dr. C. M. Green, A Case of Puerperal Tetanus. Dr. W. F. Whitney, Pathological Specimens. Supper at nine o'clock. All members of the Massachusetts Medical Society are cordially invited to be present and to take part in the discussion.

T. M. RORER, M. D., Secretary.

GYNÆCOLOGICAL SOCIETY OF BOSTON.—The next regular meeting of the society will be held at the Medical Library rooms, 19 Boylston Place, the second Thursday of May at 10.30 A. M. Paper by C. A. Perkins, M. D., on Induction of Premature Labor. Discussion upon Epithelioma in its Gynecological Bearings. Profession invited.

HENRY M. FIELD, M. D., Secretary.

BOOKS AND PAMPHLETS RECEIVED.—Ethylization: The Anæsthetic Use of the Bromide of Ethyl. By R. J. LEVIST, M. D. (Reprint.)

Tetanus terminating fatally from Enucleation of an Eyeball. Reported by JULIUS J. CHISOLM, M. D. (Reprint.)

On the Removal of Foreign Bodies from the Eye. With Four Cases. By Charles Stedman Bull, M. D., Surgeon and Pathologist to the New York Eye and Ear Infirmary.

Die operative Behandlung der Pleuritis bei Trousseau. Inaugural Dissertation. Von Otto von Gizeky. Berlin: H. S. Hermann.

Quarterly Report of the Medical Officers of the United States Army, with their Stations and Duties, as reported April 1, 1880. Washington: Surgeon-General's Office.

The Problems of Insanity. A Paper read before the New York Medical-Legal Society. By George M. Beard, A. M., M. D.

Address on State Medicine. By Thad. M. Stevens, M. D. Indianapolis, Indiana.

A Practical Treatise on Nervous Exhaustion (Neurasthenia). By George M. Beard, A. M., M. D. New York: William Wood & Co., 1880.

The Uterine Glands of the Uterus. By Prof. Giovanni Battista Ercolani. With a Quarto Atlas of Fifteen Plates. Translated from the Italian under the direction of Henry O. Marcy, A. M., M. D., Vice-President of the American Medical Association, etc. Boston: Houghton, Osgood & Co. The Riverside Press, 1880.

A Guide to the Practical Examination of Urine, for the Use of Physicians and Students. By James Tyson, M. D. Third Edition. Philadelphia: Lindsay and Blakiston.

Original Articles.

THE PRESPHYGMIC INTERVAL, OR TIME REQUIRED TO START THE ARTERIAL PULSE AFTER THE BEGINNING OF THE SYSTOLE OF THE VENTRICLE.¹

BY A. T. KEYT, M. D., CINCINNATI, OHIO.

A DEGREE of asynchronism between the beat of the heart against the chest-wall and the carotid pulse is discernible to the delicate and practiced touch. Such interval is more plainly shown by the use of two instruments, constructed on the principle of Herrison's sphygmometer, and supplied with elastic tubing of equal and convenient length to permit the glass tubes to be placed side by side for ready observation. When the pulse bases are in position, one on the heart and the other on the artery, the liquid columns first strike the eye as oscillating in alternation, one ascending while the other is descending, and *vice versa*. Observations to this effect, and by the means just described, were made by Dr. Scott Alison in 1856.²

The sphygmometric part of my differential or compound sphygmograph utilizes the principle of Herrison's instrument, and with it I have observed, time after time, when the bases were placed respectively on the heart and carotid artery, that the liquid columns appeared to rise and fall in alternation. Close inspection, however, discloses that the relation of these movements is not one of perfect alternation, but of succession.

Happily we now have the graphic method which not only demonstrates the succession of the cardiac and carotid pulsations, but permits us, also, to measure with precision the duration of the cardio-carotid interval.

The experimental proof that a cardiogram taken from the chest wall represents the phases of the cardiac revolution, and that the basal point of the main ascent marks the beginning of cardiac systole, has been furnished by Marey in one of his celebrated experiments on the horse. Simultaneous inscriptions of the blood pressure in the interior of the right ventricle, and of the heart's action against the chest wall, showed correspondence with each other in the essential points, and exact synchronism in the beginning of the two up-strokes. Marey also demonstrated, in an experiment of his series on the horse, that the two ventricles begin to contract precisely at the same time; and in another place he states that he has never observed default of synchronism between the two ventricles. Thus we are prepared to accept the cardiograms obtained from the chest wall of man as correct representations of the movements of the human heart, and, especially as concerns the present investigation, to accept the basal point of the main ascending line as marking the beginning of ventricular systole. In yet another experiment of Marey's series on the horse, one sound was lodged in the left ventricle, and another in the aorta just above the valves. The inscriptions thus obtained showed that the blood pressure in the ventricle began to rise a notable time before the beginning of the rise in the aorta. The interval between these beginnings represents the time elapsing after the ventricle begins to contract until the aortic valves open and the blood begins to escape into the artery. This is the pre-

sphygmie portion of the systole of the ventricle, or the *presphygmie interval*, as I term it, — the *syssasis* of A. H. Garrod.³

As it has been proved that the pulse wave rises later in an artery removed from the heart, evidently observations between the heart and an arterial point beyond the root of the aorta will give a time difference, made up of the presphygmie interval and the time required for the pulse wave to travel from the aortic orifice to the point designated, the transit time of the pulse wave.

To determine the duration of the presphygmie interval in man, simultaneous tracings of the heart and carotid pulse are obtained with an accompanying chronogram, or in the presence of a known velocity of the surface receiving the inscriptions, and the time difference thus ascertained is noted. Next, the transit time between the aortic orifice and carotid point is determined by a method presently to be described. The latter time deducted from the former gives the presphygmie interval.

The duration of the heart-carotid interval in man has been investigated. Czerniak⁴ in 1864, by means of his photo-sphygmograph, measured the interval at .087 second. Mosso,⁵ by means of a cardiograph for the heart and a tambour device for the carotid pulse, measured the interval at between 10 and 11 hundredths of a second.

By means of an apparatus of great convenience and accuracy, consisting of two uniform sphygmographs of transmission and a chronograph, all writing on the same smoked slide, I myself have made a very large number of observations and measurements of the heart-carotid interval. I believe that I have the advantage of other experimenters in the facility with which I make these observations, and my method employed with reasonable care admits of no material fallacy. My results demonstrate:—

(1.) That the interval is subject to considerable variation in the same individual, and in different individuals compared with each other. See cuts⁶ Nos. 16, 23, 56.

(2.) That the interval varies inversely with the pulse rate, directly with the pulse duration. See Nos. 16, 37, 56, all from the same person.

(3.) That the average duration of the interval, with pulse at 75 to the minute, four fifths of a second long, is about .08 second.

According to these data, a pulse of 60, one second long, will give the interval one tenth of a second, and the rule may be formulated that the average cardio-carotid interval is one tenth the duration of the pertaining pulsation. This rule is approximate only, for the interval varies from other factors besides pulse frequency; nevertheless, I have found it of practical value in determining approximately what should be a standard time difference for a given pulse rate.

Accepting, then, .08 second as a standard heart-carotid interval in health, with pulse at 75 per minute, in pur-

⁶ The accompanying engravings are used to illustrate, in a general way, an indefinite number of observations. My deductions are based upon my whole experience, and in some instances statements in the text do not exactly accord with expressions of the plates. The discrepancies, however, are few and small, and I can say that my larger experience confirms, in a remarkable manner, the results of my earlier work.

¹ Read before the Cincinnati Medical Society March 23, 1889.

² The Lancet, Ann. Ed., 1856, page 526; 1857, page 240.

suance of our investigation, we now seek a standard transit time of the pulse wave over the arterial tract included. As the aortic root is not accessible for observation in man, obviously the desired data must be arrived at indirectly. This is the method: The velocity of the pulse waves over other arterial tracts is ascertained, and if these are found to differ, the velocity over the arterial tract most nearly corresponding with that between the aortic root and carotid point is selected as the basis for computing the cardio-carotid transit time.

If I could find any trustworthy observations on the velocity of the pulse-wave along different portions of the arterial tree outside of my own, I would gladly present them here. In default of such findings, I am compelled to draw exclusively from my own results. Without entering into details, I will here say that my experiments in reference to the matter in hand have demonstrated the following facts:¹—

The mean average velocity of the pulse wave from the carotid point to the dorsalis pedis is 361 inches per second; from the carotid to the radial 290 inches per second; from the carotid to the femoral 269 inches per second; from the femoral to the dorsalis pedis 464 inches per second.

Thus the pulse-wave velocity over different arterial tracts is shown to vary in an important sense. The tract between the carotid and femoral is most closely allied to the tract between the aortic root and carotid; the similarity, indeed, is very intimate; accordingly, we utilize for our purpose the carotid-femoral pulse-wave velocity.

The measurement of the arterial length between the aortic root and carotid point is placed at 7 inches. Hence $\frac{7}{269} = .026$ second expresses the duration of the interval sought.

The pulse-wave velocity, as has been determined, though differing considerably in different individuals, in the same individual is subject only to a limited variation, even under considerable changes of the circulation, and variations of pulse frequency exert upon it no appreciable disturbance. (The latter fact has also been demonstrated by Garrod.) Therefore, for the short distance of 7 inches, .026 second may stand as an approximate quantity to express the cardio-carotid transit interval for any pulse rate or order of conditions, aortic aneurism alone excepted.

These data give the formula: Cardio-carotid interval, with pulse at 75, .08 second, less the cardio-carotid transit interval .026 second, equals the presphygmie interval .054 second. Then, in any case, physiological or clinical, aneurism within the included tract excepted, to find the presphygmie interval it is only required to find the heart-carotid interval and deduct from it .026 second.

But, inasmuch as the presphygmie varies largely, and the transit for the short arterial length in question inappreciably (aneurism excepted), the cardio-carotid interval practically represents the presphygmie.

Garrod, studying this subject from a basis of experimental observation of the cardiac and radial pulsations, arrived at the theoretical conclusions that the cardiac systole varies inversely as the square root of the pulse rate, and the cardiac systolic portion of the pulse varies inversely as the cube root of the pulse rate; the operation of these rules being to reduce

rapidly the presphygmie interval as the pulse increases in frequency, and at 170 to render it *nil*. Garrod's results from his equations make the presphygmie intervals much shorter throughout, and the rate of reduction more rapid than mine.

My observations do not, as yet, enable me to determine the limit of pulse frequency on the one hand, and of infrequency on the other, at which the cardio-carotid interval ceases to vary, as enunciated, inversely with the pulse rate: between 120 and 60 I am quite sure the rule holds; beyond these there appears to be uncertainty.

By my rule of reduction the presphygmie interval would become *nil* at 230, and at 180 it would be $\frac{1}{1000}$ of a second; yet it is scarcely possible that it should become *nil* even if the former rate could be reached, and the probability is that the shortest permissible interval would exceed that just mentioned.

The variations of the presphygmie interval will bear further elaboration. It often varies in the same healthy person at the same sitting with the same pulse rate; but the range under such circumstances is limited. The explanation of this variation I find in the incessant minor changes in the manner of the heart's movements and relative changes of blood pressure in the ventricle and aorta: at one systole the contraction is quicker, shortening the interval; at another it is slower, lengthening the interval; at one ventricular discharge the arterial pressure is higher, delaying the opening of the valves; at another it is lower, precipitating the opening of the valves. The reality of these incessant changes is exemplified in the cardiac rhythmic changes my observations² have shown to take place,—changes in successive pulsations and successive systoles and diastoles in hearts whose action appeared the most regular.

The interval varies more notably in different healthy individuals with the same pulse rate. This fact finds its explanation in individual characteristics, the same as a pulse rate, or pulse form, or quality of the heart's action, peculiar to different persons.

But as before presented the great variations are correlative with the variations of pulse rate. A difference of a few beats per minute may not cause a difference of interval sufficient for certain measurement by present means; yet, other things being equal, it is probable that any change of pulse frequency changes the presphygmie interval. A variation of ten per minute will almost always show a notable difference in the interval. (See No. 56.)

This correspondence between the presphygmie interval and the rate of the pulse is an interesting and significant fact, and one of a distinctive group we had never known but for the precision of the graphic method. In explanation, to my mind the interval shortens as the pulsations shorten, because: (1.) The abbreviation of the cardiac pulsation tends to abbreviate all its component parts. The length of diastole is markedly diminished as the pulse rate is increased, and the length of systole, although not so regularly corresponding as diastole to moderate variations of pulse rhythm, nevertheless, is found shorter in frequent than in infrequent pulses. The presphygmie interval, being a component part of the cardiac pulsation, is naturally proportional to its duration. (2.) In frequent pulsations the cardiac muscle contracts quicker, and

¹ New York Medical Journal, February, 1878; Cincinnati Clinic, April 13, 1878.

² New York Medical Journal, July, 1878; Cincinnati Lancet and Clinic, August 31, 1878.

more rapidly raises the ventricular blood pressure to the point of forcing the aortic valves. (3.) The accelerated blood current in its passage through the heart, with the usually free passage through the capillaries, constantly tends to surcharge the ventricle and deplete the arteries, thus favoring the earlier opening of the valves.

THE VARIATIONS OF THE PRESPHYGMIC INTERVAL IN DISEASE.

The duration of the presphygmic interval varies immensely in disease. The clinical bearings of these variations are in process of development. Already, facts of exceeding importance have been ascertained. Thus it has been demonstrated that the cardio-carotid interval, which, as shown, stands for the presphygmic, is remarkably increased in mitral regurgitation. I have measured the interval in a considerable number of cases of mitral insufficiency, and always found abnormal delay of the carotid pulse; nor have I yet found it absent in any case in which there was a positive diagnosis of this lesion.

The case of Joseph A., aged nine years, suffering from mitral regurgitation in a pure form, as diagnosed during life and confirmed post mortem, gave a heart-carotid interval of .117 or $\frac{1}{8}$ second, with pulse at 100. (See No. 42.) This is about double the normal interval at that pulse rate, estimating the normal cardio-carotid interval at the age instanced the same as in the adult. My observations have shown, however, that the pulse-wave velocity is slower and the presphygmic interval is shorter in young children than in adults.¹ The application of these facts to the present case evidently would show a still greater lengthening of the presphygmic interval over the normal.

In the case of S. R., aged twenty years, whose clinical history and physical signs afforded positive evidence of mitral regurgitation, the cardio-radial interval measured .222 + or $\frac{1}{2}$ second. (See No. 47.) Deducting from this .0714 second, as the more usual carotid radial time difference, gives .1508 second as the near approximation of the heart-carotid interval in this case with pulse at 80. This will be noted as twice the normal interval at the given pulse rate.

Again, it has been demonstrated that the carotid pulse is abnormally delayed on the systole of the ventricle in that state of the aortic valves designated as *heavy*, the condition in which, owing to organic changes, their play is sluggish and they open with difficulty.

The case of Dena H., aged thirty-one years, presenting mixed cardiac murmurs, basic and apex, systolic and diastolic, and revealing post mortem the aortic valves loaded with enormous vegetations and the mitral valve incompetent, gave for the heart-carotid interval .25 or $\frac{1}{4}$ second, with pulse at 100. (See Nos. 51 and 52.) Obviously, this is about four times the normal measurement at the pulse rate given. It may be thought that the demonstration fails, inasmuch as the delay might be charged wholly to the mitral reflux; but the pronounced systolic murmur with thrill at the second right interspace, and the heavy state of the aortic valves found after death, prove that great difficulty existed at the aortic opening, while the form of the pulse trace — its amplitude, tension, height, and fullness of the second wave — is inconsistent with the

idea of sufficiently free regurgitation through the mitral orifice to account for the very great pulse retardation. Thus I am convinced that an important part of the delay in question was contributed by the heavy aortic valves.

The case of Chris. H.,² aged thirty-one years, presented the greatest pulse retardation I have ever observed. He had systolic murmur accentuated both at the apex and second left interspace, and his post mortem showed mitral insufficiency, thickened yet competent aortic valves, and two considerable aneurismal pouches near the origin of the aorta. Simultaneous tracings of the heart and subclavian arteries showed two fifths ($\frac{2}{5}$) of a second as the delay of the subclavian pulse on the heart. In this case a part of the enormous delay was due to the aneurisms, but unquestionably the much larger part was due to the mitral insufficiency and heavy aortic valves.

Yet another important fact has been developed by François-Frauck,³ who has shown in opposition to authoritative teaching that the cardio-carotid interval is shortened in large aortic insufficiency. When opportunity presents me to measure the interval in a case of free aortic reflux, I confidently expect to confirm M. Frauck's observation; for in this condition the base of the arterial column rests against the sides of the ventricle instead of against the aortic valves, and is advanced, causing rise of the pulse with the first movement of ventricular contraction, insuring thus a short interval between cardiac systole and arterial expansion. Indeed, in a typical case of open aortic valves I expect to find the carotid pulse delayed on the ventricular systole little, if any, more than the transit time of the pulse wave between the points concerned.⁴

The remarkable range of variation of the cardio-carotid interval in disease, thus demonstrated, in the face of the comparatively very small variation in health opens the way for new and invaluable additions to our diagnostic resources. The few facts presented afford positive and precise indications of the existence and gravity of certain cardiac valvular lesions, and are an earnest of the rich harvest of results that may be expected to follow this line of observation.

In further remark as to the facility with which these observations are made, I will say that with my combined instrument I make them as readily as I would conduct an ordinary physical examination of the heart. The patient is not annoyed, but usually pleasantly interested in the procedure. The apparatus is sufficiently simple, its adjustments are easily made, and with due care any one with a steady hand may soon learn to use it with entire success.

EXPLANATION OF THE PLATES.

The three tracings on each cut were taken simultaneously; the lowest one being a chronogram, marking fifths of seconds between the points.

The space between the lines B and C shows the difference of distance between the basal points of the respective pulsations and the signal lines A, A'; the figures near express the value of this difference in fractions of a second as measured on the

² New York Medical Record, February 14, 1880.

³ Comptes rendus Ac. Sc. L xxxvii, p. 296.

⁴ Since the above was written, by the kindness of Dr. C. G. Comings, I have been permitted to trace a case in the Cincinnati Hospital diagnosed by that able clinician as one of aortic insufficiency. The tracings show the characteristic features of this lesion and a cardio-carotid interval of one thirty-second of a second, with pulse at 100.

¹ New York Medical Journal, July, 1878; Cincinnati Lancet and Clinic, August 31, 1878.

chronogram below. The figures placed above a pulsation indicate its rate per minute. In Plates III. and IV. time differences are expressed by figures placed below the distal basal point,

without indicatory lines. In Plates I. and II. the tracings are by reversal of the bases to prove the accuracy of the instrument. Other features are self-explanatory.

THE SIGNIFICANCE OF ALBUMINURIA AS A SYMPTOM.¹

BY CALVIN ELLIS, M. D.,

Jackson Professor of Clinical Medicine in Harvard University.

EPIDEMIC.—The extraordinary epidemic of albuminuria described by Limousin (8) occupied a period extending from March to June, 1857, when there was no disease prevalent to explain it. Thirty cases were seen in which, without any known cause, persons were attacked in the midst of perfect health with general œdema, dyspnoea so severe as to threaten life by asphyxia, and albuminuria. The albumen varied in amount in different cases, being sometimes very large, but almost never absent, and disappeared with the œdema and dyspnoea. With no further knowledge of this anomalous epidemic, we can draw no very accurate conclusions, but may suggest that dropsy alone furnishes a source of albumen when all parts of the body are affected.

EPILEPSY.—As albumen has not always been found in this disease (80; 81, p. 75), we give in some detail the investigations of Huppert (6, p. 369), who first assured himself that the urine was normal under ordinary conditions, then examined that passed after the commencement of an attack, without finding albumen, as the contents of the bladder at that time were secreted before the paroxysm. These precautions being taken, the urine was tested three quarters of an hour after the attack, and other portions subsequently, until the tests no longer showed albumen. In severe cases, the abnormal condition lasted three or four hours, more rarely six or eight, and still more rarely only two, the largest amount being found in the first portion examined, about three quarters of an hour after the attack, from which time it gradually diminished. The more rapidly the paroxysms followed each other, the more abundant was the albumen. Though the quantity was apparently greater in cases of long standing, the amount was generally sufficient to cause opacity only, though at times flocculi were seen. The albumen was not due to the presence of blood, for, after severe attacks, there were never more than one, two, or three, red blood globules seen; and these were excessively rare, even in cases where petechiæ appeared in the conjunctivæ or eyelids. The writer assured himself that the urine must contain a much larger number of corpuscles before it becomes albuminous. Colorless corpuscles were more common; indeed, were hardly ever absent. The vertiginous attacks of epilepsy, where they succeed each other rapidly, may also be followed by albuminuria, but this is often wanting. These observations are confirmed by Dr. De Witt, who found albumen in more than twenty cases (104).

ERYSIPELAS (45, p. 265).—Albumen is most likely to make its appearance in severe cases. This is equivalent to saying, what is often true, that it depends not upon erysipelas as a disease, but upon the extent of the morbid processes in any given instance. As an explanation, we have the fever and perhaps some secondary though transient changes in the tissue of the kidneys.

EXERTION.—We have selected this head as expressing the most probable supposed cause. Edlefsen noticed in three healthy but anæmic men transient albuminuria after bodily effort (92).

Leube (28) examined the urine of a large num-

ber of healthy soldiers in the morning, and found it normal, but after a five hours' march, or severe exercise, in the months of June, July, and August, with a temperature of 54° to 77° F., it contained albumen in sixteen per cent.; though the amount was small, perhaps just perceptible, and never exceeded one per cent. This could not be detected when another examination was made between four and six p. m. There were no casts nor blood corpuscles. The same has been seen, under similar circumstances, in army officers, in connection with scanty urine, and also in nervous persons (97, p. 345). The specific gravity has been at times high. In such cases peculiar variations, diurnal or longer, occur, in which there is no albumen, and the latter may disappear without returning, and without any special change in the mode of life. It is most natural to suppose that its presence was owing either to some variation in the blood pressure, or to some change in the vessels. The rapidity of its appearance and disappearance makes it extremely improbable that there was any change in the vessels, and we are left with a variation of the blood pressure. The view that the last might be operative seems to be supported by the statement of Ranke, that the blood accumulates in the muscles of a healthy man during exertion, while it is diminished in the organs which are at rest.

Edlefsen (97, p. 345) always found congestion of the lesser circulation in the bodies of soldiers who died on the march in consequence of exertion. It is suggested, also, that the deficiency of water in long-continued exertion may favor the diminution of pressure more than muscular effort. But if exertion causes albuminuria through a diminution of pressure, such a result does not necessarily follow, as was shown by Fürbringer's own experience. After a long mountain climb in the summer, with profuse perspiration and scanty urine of a high specific gravity (1030–1033), no trace of albumen was found. We must admit, however, that, until we know through farther investigations whether any change of pressure takes place, our solution is merely plausible. We must not forget, in this instance, the possible influence of the nervous system, which might well be affected by prolonged exertion.

FEVER.—There is hardly any affection accompanied by severe fever in which albuminuria may not show itself as a transient symptom, independent of the localization or nature of the disease (1, v. 9^e, p. 45; 35, p. 249). No positive law can be laid down in regard to its manifestation; inappreciable individual differences seem to control it. In some it is met with early, in others late, and is not always in proportion to the rise of temperature, being absent, perhaps, when the latter is 104°. In all acute diseases it disappears as patients recover; or, if they die, no structural changes are found which may not also be found where there is no albumen. Persistent structural disease rarely follows the febrile affections, and if it does it is by no means certain that it is dependent upon the increased temperature (35, p. 347). The idea that it is connected with any special poison in the blood is inconsistent with the fact that we do not always have it in certain diseases where such might be the explanation, and that it is seen at various periods, perhaps early, and disappears before the temperature falls, perhaps late, even during convalescence (35, p. 249). In scarlet fever itself it may be detected before the kidneys are appreciably affected, merely be-

¹ Concluded from page 388.

cause there is fever (16, v. 2, p. 862). Bartels and other observers have supposed that it might be attributed to direct paralysis or relaxation of the walls of the capillaries of the kidneys in consequence of the high temperature, but this is hypothetical (35, p. 248). Though Runeberg's experiments show that the permeability of membranes increases with the temperature, the increase within the body is not sufficient to produce it alone (35, 253). We must not forget that in the febrile diseases we have, besides the increased temperature, decided derangements of the circulation, caused partly through changes in the tissue of the heart, partly by the effect of the high temperature on the nervous system (35, p. 249). As a consequence of this interference, when the elevation of the temperature lasts some time, according to Liebermeister (65, p. 475), we have increased rapidity and weakness of the contractions of the heart, and, in the adynamic forms of fever, excessive diminution of arterial pressure and great rapidity of the circulation (65, p. 469). The pulse is quick and easily compressible, the quantity of urine is small, and albumen makes its appearance. Experiments with the new instrument devised by Marey (62) show that in this form of disease the pressure of the blood in a finger may fall to three cc., while it rises to twenty cc. in interstitial nephritis. Though Bartels has advocated the view of congestion, he does not think it possible to explain the appearance of albumen by this, as in many cases it is not found, and when present it may be combined with inflammatory swelling and infiltration (1, v. 9, p. 170).

Having demonstrated that a marked influence is exerted by the nerves over the blood-vessels, it must be accepted as at least one element in the albuminuria of febrile diseases. Still it cannot be denied that, after the long duration of fever, the elements of the kidney may be changed, particularly the walls of the vessels, and constitute permanent disease, just as serious changes of nutrition may follow section of the nerves of vessels, if the animal live long enough (1, v. 9, p. 48). The red globules may also be so changed as to furnish albumen. Other complications may intensify the effect, and must be noted as they arise.

FEVER, INTERMITTENT.—The diversity of opinion about the frequency of the occurrence of albuminuria (16, v. 2, p. 862), as well as that about the time of its appearance (45, p. 241; 52, v. 2, p. 29), warrant the belief that it certainly is found at any time during the paroxysm, and that it may persist in the intervals. Blood and casts may also be seen. Though the albumen generally disappears with the fever, chronic disease of the kidneys may follow, and even amyloid, as a consequence of the general cachexia. In cases which have proved rapidly fatal there has been found marked congestion, with acute swelling and the deposition of pigment.

FEVER, MILK.—The effect of the preëxisting pregnancy being carefully eliminated, albumen may be detected (45, p. 268).

FEVER, PUERPERAL.—This furnishes us with many instances (45, p. 268).

FEVER, TYPHOID.—Many writers concur in stating that albuminuria is very common, and that the amount is considerable (52, p. 188), but it disappears with the disease in the vast majority of cases (45, p. 250).

FEVER, TYPHUS.—The urine is more frequently albuminous than in typhoid, it being noticed in a very large proportion of the cases towards the height of the

fever, and even on the sixteenth day, but it lasts only four or five days (45, p. 260).

FEVER, YELLOW.—Albumen is never absent when the disease is severe, the quantity being so large at times as to render the urine solid (45, p. 242). It disappears, however, after recovery, even if accompanied by uræmic symptoms. According to Griesinger, renal affections never follow (52, v. 2, p. 79).

The explanation is the same as in diphtheria.

GOUT, EXOPHTHALMIC.—Albumen has been found in a considerable number of these cases (4). The amount is generally small, perhaps a mere trace, when there is no affection of the heart or kidneys, but in one instance the quantity was excessive, though recovery was complete. It is generally transient, lasting but a few days or weeks, but may continue for months, and after disappearing return, not always persisting as long as the local changes, being apparently connected with the more marked symptoms. In certain cases it was limited to the period of digestion, being present immediately after a meal, and absent when the patient fasted. It was also more abundant after breakfast than after other meals.

The urine furnished no other indications of disease. Cœdema of the lower limbs has borne no constant relation to the albuminuria, though at times present. There is always much disturbance of the nervous system, and the sufferers are often hysterical.

Judging from the marked pulsation of the arteries and the distention of the same, there is general dilatation resulting from paralysis, and, being general, the pressure would be diminished in the capillaries for reasons previously given. But we must not overlook the anæmic condition of the patients and the possible transudation of serum.

GOUT.—A small amount of albumen is not uncommon, and may perhaps be accompanied by casts, but is generally so temporary as to lead to the suspicion of true renal disease if it persist (45, p. 296.)

GUM ARABIC.—See Skin, page 417.

HÆMOGLOBINURIA.—It is necessary to mention this, as it occurs in connection with albuminuria as a distinct affection, in a transient and intermittent form. The albumen is of course derived from the dissolved blood-discs.

HEALTH, IN.—See page 362.

HEART, VALVULAR DISEASE OF.—See page 364.

HYDROGEN, ARSENIURETED.—See page 391.

INDIGESTION.—See page 389.

INFANTS, NEW BORN, ALBUMINURIA OF.—This is described by Vierordt and others as occurring soon after birth, and disappearing in a short time (47, v. 1, p. 143). It has been attributed to the irritation of the uric acid which accumulates in the tubuli, and to insufficient pressure on the glomeruli (35, p. 258). The first suggestion is plausible, as such a collection of uric acid is common, but the connection between the two has not been demonstrated. The second seems corroborated by the very small secretion of urine before the end of the third day, and the disappearance of the albumen with the increased flow, which implies a larger supply of blood to the kidneys.

INTESTINAL CATARRH.—See Catarrh, page 392.

IODINE.—Boehm (1, v. 15, p. 17) states that the urine may contain a small amount of albumen after poisoning by iodine injected into ovarian cysts. No structural change of the kidneys is described.

J. Simon made repeated applications to the heads

of children affected with favus, and after a number of days there was albuminuria in one half of the cases where the application was made to surfaces as large as ten centimetres square. It was transient, appeared with the absorption of the drug, and disappeared with the abandonment of its use. The urine was in other respects normal. It is suggested that this acts (35, p. 256) by causing a contraction of the arteries in the same way as lead, the flow of urine being thereby diminished, owing to the diminished pressure.

KIDNEYS, AMYLOID DEGENERATION OF. See page 368.

KIDNEY, CANCER OF.—Though the urine may be free from albumen through the whole course of the disease (1, p. 50), it may be present; but the amount will probably be small, unless considerable blood is lost. The same is true of other new formations.

LEAD.—That the presence of lead in the system may give rise to albuminuria has been shown both by numerous clinical observations and experiments upon animals (24, p. 530), the latter being fed with the metal, as well as exposed to its fumes. In the clinical observations upon which the statements were based, the persons affected were in good health in other respects. In the experiments on animals the time was too short for cachexia, and the consequences followed directly upon the introduction of the poison. In man albuminuria may be overlooked, unless its occasional transient character is remembered. Ollivier (24 p. 530) describes eight cases in which it appeared during the attacks of colic, and was absent in the intervals. But it may last as long as the symptoms of poisoning persist, or may be associated with real disease of the kidney, the character of this varying with the amount and duration of the action of the metal, showing all degrees: sometimes mere fatty degeneration of the contents of the tubuli; at others the permanent changes belonging to interstitial nephritis. The conviction that we have here the relation of cause and effect is strengthened by the fact that traces of the metal have been found both in the urine and kidney. But experiments have also shown that lead poisoning may take place without any affection of the kidneys (26). There seems to be doubt about the immediate action of the lead upon the kidney (26), as the albumen appears and disappears with the paroxysms of pain (35), during which there is contraction of the muscles of animal life throughout the body. The muscles of the minute arteries participate, and we have, as a consequence, a diminished flow of blood and urine.

MANIA, TRANSITORY.—Temporary albuminuria with a few hyaline casts has also been observed in the paroxysms of excitement of transitory mania, lasting half an hour or more (6, p. 394). The disturbance of the nervous system probably causes derangement of the circulation of the kidneys, as in other similar cases.

MEASLES.—It is very common in some epidemics. Commencing with the eruption, it may then disappear, to return when the rash fades (82); though when the latter is very tardy, the albumen may be absent. Blood globules may also be found in the urine, and evidences of some structural change of the kidneys may be first seen after the fever has passed away, as in scarlatina. Here we have as causes fever, blood, and renal disease.

MERCURY.—The use of this is sometimes followed by temporary albuminuria, which disappears permanently as the symptoms of mercurialism subside (79, p. 554).

MILK, INTRAVENOUS INJECTION OF. See page 390.

MIND, DISTURBANCE OF.—Fürbringer (97) reports the case of a physician twenty nine years old, in whom albumen appeared, with a diminution of the quantity of urine, under the influence of mental strain, grief, or fear, while it was sure to be absent when the mind was at ease. The ingestion of a large quantity of fluid did not promote diuresis while under the same depressing influences, but by increasing the flow of urine the albumen could be made to disappear. Neither food nor ordinary movement was followed by albuminuria, while haste caused it.

After a duration of eight months there was so marked a diminution of the symptom that great exertion produced no effect, and after a vacation of some weeks in the mountains it was absent.

Johnson (94, p. 930) thinks that an increase of albumen in chronic renal disease may, at times, be traced to the same cause. The supposition is that, through reflex irritation of the inhibitory centre, the power of the heart is diminished, the arteries in consequence receive a smaller supply of blood, and the tension of the glomeruli becomes less. This seems confirmed by the diminution of the quantity of urine.

NERVOUS SYSTEM. See page 366.

NITRE.—Bartels states in a general way (1, v. 9, p. 171) that large doses of this drug may give rise to hyperæmia of the kidneys; but it is very difficult to obtain any definite proof of the appearance of albumen. Dr. Lawrence's case (93) of a young man eighteen years of age, whose urine became albuminous after using an ounce of sweet spirits of nitre daily for three weeks, is not reported sufficiently in detail to make it unequivocal, though it is to be supposed that the previous and subsequent conditions of health were ascertained.

OXALURIA.—Four cases with albuminuria are reported (70), but in three of them there was blood. The quantity of oxalate of lime was large. In one there were epithelial casts. The presence of bladder epithelium indicated irritation of that organ also.

OIL OF ACAJOU. See Skin, page 417.

OIL, CROTON. See Skin, page 417.

OIL OF HEMP OR FLAXSEED. See Skin, page 418.

PARALYSIS, GENERAL.—In this, as well as other severe affections of the central nervous system, albuminuria is probably owing to the influence exerted on the circulation (35, p. 247).

PETROLEUM. See Skin, page 417.

PHOSPHORUS.—While there is a difference of opinion about the amount of albumen and the frequency of its appearance (11; 23, p. 257), it is admitted that there is fatty degeneration of the cells, and to this hyperæmia and enlargement of the kidneys may be added (32).

When the organs are swollen, the circulation would, necessarily, be more or less interfered with; but when the cells are alone changed, as described, they would by accumulating in the tubuli, and interfering with the escape of the urine, so equalize the pressure on the two surfaces of the glomeruli as to favor the escape of

albumen. But such an accumulation would be expected only in the most marked cases.

PLEURISY.—Though seen, albumen is not common (45, p. 281).

The febrile character of the affection would be a sufficient explanation at times; but the interference with the circulation might often exert a great influence.

PNEUMONIA.—Albuminuria is present in a large proportion of the cases (45, p. 276). It begins generally at the height of the disease, or, possibly, may be first noticed with convalescence, or after recovery (16, v. 2, p. 863), but it may not occur with very extensive consolidation (45, p. 278), and is not always in proportion to the extent of the local affection. Casts are very common, and blood may be seen in small quantities, but not in proportion to the albumen. The explanation seems simple. We have two important factors: first, the interference with the circulation in the lungs, which must be felt throughout the body, and consequently in the kidneys; second the high temperature of acute inflammation, which we have already seen is sufficient to cause albuminuria. A certain amount of morphological change is also probable.

PNEUMONIA, CATARRHAL.—Observers differ much in their statements of the frequency with which albuminuria occurs (45, p. 319), and this must necessarily be the case if the different stages of the disease are overlooked. The appearance of albumen does not in all probability depend upon the pathological condition as much as it does upon the accidents and varieties of constitutional disturbance accompanying it, and the quantity must vary accordingly. It cannot be attributed to the diminution of the aerating surface connected with destruction of tissue, atrophy, or emphysema, for there are no indications of cyanosis in the vast majority of cases, and the quantity of blood diminishes with the progress of the disease. Fever must often play a very important part, and there may be structural disease of the kidneys themselves. Accurate observations about the time when the albumen appears might throw much light upon the subject.

PREGNANCY.—In addition to the albuminuria caused by convulsions during parturition (41, p. 68), and by pressure on the veins, we have a form dependent upon a change of the kidneys, resembling that of acute nephritis, and constituting one of the most frequent of purperal diseases. It is rare before the sixth month, more frequent in first than in subsequent pregnancies, and liable to return (10, p. 13). In many cases it disappears with the other evidences of renal disease during or soon after convalescence (41, p. 69), though the amount is generally large.

The statement that the changes resemble those of acute nephritis carries the explanation with it.

PURPURA.—See Scurvy, page 417.

PCS.—See page 363.

RHEUMATISM, ACUTE.—Though albumen is not uncommon, it may last only a single day, and the amount is usually small. Blood or elements of the kidney are rarely met with (45, p. 290).

SCARLATINA.—It is seen in a large proportion of the cases, though not in all, the frequency varying according to the character of the epidemics (45, p. 263).

It may appear at the beginning of the disease (1, v. 2, p. 215), but it is most common after the sixth day (45, p. 263) and during desquamation, lasting but a few days. Sometimes it returns when the dropsy comes

on, two or three weeks later. When the renal disease is well marked it resembles that of acute parenchymatous nephritis, and the urine is consequently similar in its character.

We have here three distinct causes,—the fever, the renal disease, and the dropsy, though the latter may occur without albuminuria.

SCURVY.—Immerman (1, v. 13⁹, p. 625) states that it is frequent, but marked only in severe cases. There is often no demonstrable anatomical lesion of the kidneys. Still we may suppose some change of the vessels, which, though not demonstrable, may be sufficient to allow the albumen of the blood to escape, as is seen in other parts, and which, when still more strongly developed, may give rise to hæmaturia.

SEPTICÆMIA.—See page 390.

SKIN, APPLICATION OF GUM ARABIC TO.—The experiments on animals reported by Feinberg (86) were followed by congestion of all parts of the body, and, at times, extravasations of blood, with more or less advanced parenchymatous inflammation of the kidneys.

This congestion was attributed to the paralysis of the vaso-motor nerves, properly traceable to the irritation of the peripheral nerves. As other evidence of disturbed innervation, there were increased reflex action, tremors, convulsions, incomplete paralysis, slow respiration, and weakening of the action of the heart.

To show that the results were not owing to cold the animals were protected by cotton-wool, but such a precaution was probably unnecessary, as experiments seem to show that rabbits whose skins have been treated in this way die at the same time, whether the bodies have been protected by cotton or not.

SKIN, APPLICATION OF MUSTARD TO.—Mustard when absorbed after the application of poultices may cause active hyperæmia of the kidney and excite true inflammation (1, v. 9⁹, p. 171), but as persons rarely die from its effects, we cannot claim that the changes produced are known. If, however, we have evidence of true inflammation during life, we have also an explanation of the albuminuria.

SKIN, APPLICATION OF OIL OF ACAJOU TO.—When a large surface is covered with this, its absorption may be followed by hyperæmia and even true inflammation of the kidney (1, v. 9⁹, p. 171).

SKIN, APPLICATION OF CROTON OIL TO.—Lassar (101, p. 158), after removing the hair from rabbits and dogs, applied to the denuded surface croton oil, which excited the usual inflammation. The animals treated in this way secreted a highly albuminous urine, and died in a few days. The kidneys showed no changes except in the cells. To prove that this result was due to the absorption of the oil, and not to the inflammation, he excited extensive suppurative in the subcutaneous cellular tissue by injecting a five per cent. emulsion of turpentine, but no albuminuria followed. These experiments seemed to indicate that the changes in the skin and kidneys were coeffects of the same agent, acting upon different parts of the body in its passage through it. Indifferent oils passed without causing trouble.

SKIN, APPLICATION OF PETROLEUM TO.—Lassar (17) cites a case of scabies, in which petroleum was applied to the skin of the whole body of a healthy man for four days. A week after, oedema began in the feet and extended upwards. There were marked albuminuria and casts until he died, after an illness of four months. The temperature was normal. A mi-

eroscopic examination showed a localized inflammatory process in the skin, but no anatomical change in the kidneys. No other cause of albuminuria was noticed. Later observations of the same writer make this matter much clearer. After taking every precaution to prevent the introduction of oil except through the skin (101, p. 166), he found in the subcutaneous tissue, the kidneys, and other parts of the body a great accumulation of oil drops, but the appearance of albuminuria depended upon a certain continuance of the experiment. Though in the earlier stages certain modifications of the urine were noticed, described as resin urine (Iarlzlharn), pepton urine, and albumen urine, with the last only was there granular degeneration of the epithelium.

To explain this series of changes, he supposed that the oil underwent some change in its passage through the body which rendered it irritating. The same infiltration followed the application of other oils, such as olive and cod-liver, but these produced no prejudicial or irritating effect. Their use merely illustrated a point in the law of absorption.

SKIN, APPLICATION OF STORAX TO. — Uuna (27) examined the urine of one hundred and twenty-four healthy persons while storax was applied to the body for the cure of the itch, the duration of the treatment being about three days. Great care was used to ascertain that all other causes of albuminuria were absent. The urine was tested in the morning, after one, two, or three applications, and until the termination of the treatment. If albumen were detected the patients were kept under observation as long as possible. In two instances the urine was tested every four hours. In the last twelve cases an examination was made before each application. The nine cases upon which the proof of albuminuria was based showed large, thick flocculent deposits; the others, in which only a trace of albumen was found, were rejected. The most marked feature was the rapidity with which the albumen appeared and disappeared. That the drug escaped through the kidneys was shown by the peculiar odor of the excretion, and yet no mention is made of any casts or other evidence of structural change.

It is difficult to explain the appearance of albumen in this connection. As we have but two factors to work with, namely, the agent applied and the albuminuria, we cannot attach much value to the solution offered by the reporter of the cases, as the supposition that the higher atomic weight of the particles of abnormal matter allowed them to pass more readily through the walls of the capillaries is only a supposition, however probable it may seem, as the odor of the urine shows that something does pass.

SKIN, APPLICATION OF OIL OF HEMP OR FLAX-SEED TO. — Sokoloff (43, p. 43) experimented upon dogs or rabbits, whose skins he covered with asphalt, glue, gum arabic, collodion, and, finally, with oil of hemp or flaxseed, of the consistence of syrup. The latter proved to be the best, as it acted simply as an impermeable covering of the skin, without causing the irritation of the other applications, or restricting the mobility of the animals, and was not liable to crack. The albumen in some cases appeared soon after the application, even while the animal seemed perfectly healthy; and such was the result whether the covering was partial or relatively complete, though the consequence was more immediate in the latter case, the albumen being seen, perhaps, in the evening, after the oil had been seen in the morning, while in cases of

partial application it might not be found before the third or sixth day. But in both instances it was liable to increase from day to day, and after a time other indications of renal disease were noticed, such as formed elements. After death, there were found, in acute cases, together with inflammation of other parenchymatous organs, swelling of the cortical substance of the kidneys, diminution in size or closure of the tubuli, and opacity of the contents as well as of the epithelium of the Malpighian bodies. If the animal lived a long time after a partial use of the oil, the appearances differed from the above. The cortical substance was swollen and of a grayish-yellow color, and the tubuli were filled with a granular mass, in which the cells and nuclei could no longer be distinguished. At times there were fat drops and a new formation of connective tissue.

These experiments seem quite conclusive, but Senator (18) initiated, as he supposed, on human beings the experiments on animals, though the object was to relieve some affection of the skin. The consequences, however, were not at all serious. He therefore inferred that much depends upon the size of the animals used, the effect diminishing with the increase of bulk. The element of time seems also to have some influence, as Gerlach, in completely covering the skins of horses, noticed nothing in the first few days (43, p. 81); and it is suggested that Senator may not have continued his experiments long enough. We must also bear in mind the character of the materials used.

The experiments of Stockvis (11, v. 45, p. 218) were only partially successful, as he found traces of albumen but twice, although there was fatty degeneration of the epithelium of the kidneys, of the liver, and heart.

Sokoloff's researches seem to point to some deleterious effect upon the blood (43, p. 76), as he found that the injection of the blood of an animal which had been covered with oil into the veins of a healthy one was followed in a short time by albuminuria, which lasted three or four days. The mere tying of the jugular vein, or the injection of the blood of a healthy animal, did not produce similar results. The effect upon the nervous system must also be considered, as this may act upon the heart (35, p. 260).

Lassar's experiments (101, p. 168) make it probable that the consequences are attributable to the absorption of the oil, afterwards rendered irritating by some change it undergoes while passing through the body.

SKIN, VANISHING OF. — Although this title has been used as indicating an immediate cause of albuminuria, it conveys an erroneous impression, the applications having been so different in character as to prevent any comprehensive statement in regard to them. We have therefore considered each instance by itself.

SPERMATIC FLUID. — See page 363.

STORAX. — See Skin, page 418.

STUPOR. — See Collapse, page 393.

TETANUS. — Though not common, albuminuria does occur in these cases, and may be attributed to the spasmodic action alone. The fact that the heart becomes almost stationary (35, p. 244), while the secretion of urine is much lessened, points to diminished pressure upon the glomeruli as the immediate cause.

THIGH, FRACTURE OF THE. — Riedel (89) in nineteen cases of fracture of the neck of the thigh, found albumen eight times, and still more frequently casts and fat.

We can of course make no attempt to explain this without a knowledge of the facts in each case, but it is not probable that any new special influence would be exerted by this accident.

TRACHEA, COMPRESSION OF THE.—The experiments of Overbeck, in which the trachea was compressed, are often quoted, though Stockvis (11, v. 45, p. 209) did not succeed in verifying them.

Admitting, however, that albuminuria may follow, we can explain it by supposing diminished pressure on the glomeruli (35, p. 235), owing to the enfeebling of the heart's action by asphyxia.

TURPENTINE.—Albuminuria may be either the result of its inhalation or introduction into the stomach (1, 9', p. 171), and it disappears with the removal of the cause. In one case where the vapor was inhaled the albuminuria continued three days, and ceased before the urine lost its peculiar odor. The drug acts as a powerful irritant (29, p. 478), judging from the effects produced, but as patients rarely die we know but little about the pathological process, though we are told that there is hyperæmia or even inflammation of the kidney.

It is reasonable to suppose that an irritating substance in passing through the walls of the vessels should so alter their character as to render them more permeable, but we are not aware that such has been proved. In addition to this, however, there are structural changes, caused by cantharides and turpentine, which play an important part in the production of albuminuria.

But Lassar seems to show that to secure this result absorption must take place through certain surfaces, as the injection of a five per cent. emulsion into the subcutaneous tissue of animals was not followed by albuminuria, although extensive oedematous and purulent inflammation was excited (101, p. 158).

VARIOLE.—The occurrence of albuminuria in the course of an attack of variola has been frequently noticed (5, p. 434), though not so often as in scarlet fever, and only in certain epidemics. Consequently the statistics of its frequency differ according to the special opportunities of the various observers. As it is most common in severe, confluent, and hæmorrhagic cases, it is about three times as frequent in the unvaccinated as in the vaccinated. It has generally appeared from the eighteenth to the thirty-first day, the patients usually being young males from five to twenty-one years old. Blood and casts have also been found.

YOUTH, INTERMITTENT ALBUMINURIA OF.—In Moxon's nineteen cases (31, p. 238), in which the children, though ailing, were suffering from no special disorder, and the urine was free from other indications of disease, the closest repeated examinations showed albumen at times, though it was often wanting. Recovery was demonstrated in a number of instances.

These facts were confirmed by other observers, the albumen being absent at certain times of day, in one case disappearing while in the recumbent posture (30), perhaps showing some connection with a chill or indigestion (57).

In Fürbringer's cases the specific gravity of the albuminous urine varied from 1008 to 1031, while that of the non-albuminous varied from 1002 to 1025; but there was a very free flow at times after the diminution. The amount of the albumen was small, and generally there was no other evidence of disease, though a few times hyaline and pale casts were found (37, p. 348).

In addition to this intermittent form, Vogel (98, p. 522) refers to persons who for years have had continuous though slight albuminuria, with no other signs of renal disease, and who appear to be perfectly well in other respects.

This may continue a very long time without ending in serious disease, as is shown by a case which lasted thirty years; or it may be completely relieved after a long duration, certainly seven years (94, p. 930).

We may suggest that, some of the patients being in rather feeble health, though not subject to any special disease, the action of the heart was less vigorous than it should be, and therefore the pressure on the glomeruli was less than usual, while at the same time the tissues themselves were in an abnormal condition, and the blood-vessels might be more permeable. But this is only a suggestion without the slightest proof. Some of the cases might, perhaps, be traced back to previous disease, but many of them, offering no points for analysis, are necessarily inexplicable.

As some of the above subjects may seem to have received inadequate attention in proportion to their importance, it should be stated that care has been taken to exclude such points as did not appear to have a direct bearing upon the subject of the article.

In the course of this inquiry many important and interesting questions have presented themselves to the writer, and an answer may perhaps be expected by those who take sufficient interest in the matter to consider fully its significance.

Among these is that of the connection between renal affections and the various diseases with which they have been found associated in the careful examination of the records of large numbers of autopsies, such as that of Bamberger (91).

Any investigation of the kind, however, is foreign to our purpose. We have attempted only to show how far the present state of knowledge will enable us to explain the appearance of albumen under certain conditions. If the results arrived at be correct and the single factors understood, their combination will offer no difficulty.

If some of those mentioned as transient or unaccompanied by renal lesions should prove to be permanent, or the initial agents in the production of any of the forms of nephritis, the fact has only to be ascertained to carry the explanation with it; for the various changes of the kidneys act in certain ways, whatever their cause may be, and it is this mode of action alone we have attempted to elucidate.

RECENT PROGRESS IN DERMATOLOGY AND SYPHILIS.¹

BY EDWARD WIGGLESWORTH, M. D.

CHIRYSAROBIN AND PYROGALLIC ACID IN SKIN DISEASES.

HERRA reports² that chrysarobin has not, in his clinic, answered so well for extended territories of psoriasis as for more limited ones. Spread over large tracts, inflammation followed, succeeded in its turn, as is the custom in this disease, by psoriatic patches upon the inflamed spots. For small local patches it an-

¹ Concluded from page 396.

² Wien. med. Presse, Nos. 43, 44, 1879.

swered well. On the head it could not be used, as it dyed the skin and hair. In other diseases chrysarobin was no better than those means now employed. Pyrogallacid, however, possessed great advantages applied twice daily as a ten per cent. salve, the spots being then covered with flannel. The results were always good, the duration of the treatment was not much longer than with chrysarobin, inflammation less rarely occurred, and pigmentation was less marked. No case of poisoning took place, though the remedy could always be detected in the urine. Single patches were removed in from one to three weeks. Tinea tonsurans yielded speedily. For lupus the ointment applied on cloth for three days was often sufficient to destroy nodules, the skin healing in three weeks more with an indifferent salve; so, also, for syphilitic infiltrations and even epitheliomata, the last requiring often, it is true, more severe applications. Experiments made with pyrogallacid¹ prove, however, that it may produce toxic results, and Neisser reports² the case of a healthy man, a patient in the dermatological clinic at Breslau for universal psoriasis, half of whose body was treated by chrysarobin and half by rubbing with the ten per cent. pyrogallacid ointment. Chills, vomiting, and collapse followed, repeated forty hours later, and on the fourth day death ensued, with coma and marked fall in the temperature of the body. The urine (1600 c. cgm. in the four days) demonstrated to the highest degree haemoglobinuria. Controlling experiments made upon rabbits showed no change after the application of chrysarobin; chills, dyspnoea, tremor, collapse, and death after pyrogallacid (two grm. to one kilo. animal). These results Neisser attributes to the marked absorption of oxygen by this acid in the presence of alkalies and the consequent decomposition; which effects can be shown outside the body equally well. The therapeutics would be venesection and transfusion. Active diuresis in the early stages is also called for to render the uriniferous canal patent, as these are early blocked by a sediment. Pyrogallacid, a non-irritant, but a general poison, will do for small tracts like the head; chrysarobin, a violent local irritant, but not a general poison, is preferable only for the body.

HEREDITARY SYPHILIS.

Dr. Maximilian Zeissl records³ with admirable terseness a most clearly defined case of syphilitic infection in utero, which meets precisely the conditions demanded by Kassowitz, who denies⁴ the possibility of such infection: (1.) The father must be healthy at the moment of fecundation. (2.) The mother the same, and the moment of the subsequent infection must be exactly known. (3.) The child must be born, and must show positive marks of syphilis. Abortion is not enough, nor death in utero, nor death soon after birth, nor a weak constitution. Mr. X., a trade drummer, left his home, a healthy man, July 15, 1877. He left a healthy wife two months pregnant; last menstruation May 5th. He had connection with a strange woman in Vienna July 24th. Came to Professor Zeissl's clinic August 20th. On the inside of the prepuce was an ulcer one half c. cgm. in diameter, with tough edges and a hard base, suppurating slightly. An astringent wash was applied and secondary ap-

pearances waited for. September 23d, there appeared a maculo-papular syphiloderm and specific catarrhal angina. October 29th, Mr. X. returned to his home, the initial sclerosis still slightly indurated, to bring his wife to Vienna to be confined. He, spite of warning, had connection with his wife. Early in December, the wife, now seven months pregnant, showed to Zeissl an evident initial sclerosis on the left labium minus, and by the end of December a general macular syphiloderm. February 14, 1878, at the normal time, a living child was born, which showed, eleven days later, bullae on the soles and between the toes and a maculo-papular eruption upon the rest of the body, and died after a few days. The necropsy was forbidden by the parents. Had either parent been already infected, such one would not have had a primary sclerosis. The child showed no primary sclerosis, and had no time after birth to acquire one from any external source. The wife subsequently had a specific iritis, and in July, 1878, gummata; at which date, and in February, 1879, she aborted. Since July, 1879, both she and her husband have had good health. Is not, then, the virus of syphilis a contagium vivum, not chemically soluble, like that of variola or of scarlatina? Mauriceau, the celebrated obstetrician of the seventeenth century, was born with small-pox. Klebs discovered the helico-monas, a parasite, which he cultivated and inoculated upon an ape, producing syphilis. Zeissl rubbed cinnabar into a chancre (Aner. chancroid), and Stricker found the drug in blood taken from the patient's hand. It is not yet proved that blood globules, even, may not traverse the placenta, still less bacteria; for the most careful filtration will not free a liquid containing them from the presence of micro-organisms. Mireur has recently inoculated the sperm of a syphilitic man, with negative result; so Pellizari blood plasma, while the various inoculations with the blood of syphilitic patients have succeeded about one time in three. Yet the following goes to prove that semen may infect: In 1866 Zeissl treated a man for syphilis. This man waited one and a half years after the disappearance of every symptom, and then married a healthy woman, having first confessed to her the facts. She was examined once a week by Zeissl for six months, and never showed any primary sclerosis. Then her hair fell out, nodes came upon her shins, and her health gave way. Under iodide of potassium she recovered entirely, and in 1878 bore a healthy child, which is still alive and well. Birch-Hirschfeld concurs with Zeissl in his views upon this subject.

UNIVERSAL ERYTHEMA FOLLOWING THE USE OF CALOMEL.

Engelmann describes⁵ a general erythema following the administration during one half day of three doses of calomel of fifteen centigrams each, the patient being a healthy but nervous and thin-skinned man of forty-two years. The erythema appeared two hours after the last dose, with malaise, a dry, itching skin, photophobia, hoarseness, fever, thirst, and insomnia. The patient reported a similar condition years before after taking blue pill, and again when he had been present during the exhibition of some of the toy "Pharaoh's serpents." The fever grew daily less, and on the fourth day desquamation began. The strength and appetite were not normal, however, for a fortnight.

TRYCOPHYTIC ONYCHOMYCOSIS.

Vidal's wards in L'Hôpital St. Louis presented¹ recently this rare disease. A man, aged sixty-seven, had been anemic for nine years, with general desquamation and itching of the body, on which there were, on inspection, no hairs, while those upon the hands were broken, and, under the microscope, showed trycophyton spores. Patient left, after treatment, uncured, and returned five months later with marked *tinea circinata* of body, and with his nails thickened, raised, and showing small yellow spots under the external horny layers, due to the presence of spores. In some cases these had formed longitudinal striae, and had also separated, raised, and split off some strata of the nails, this exfoliation corresponding to the broom-like splitting of hairs. One toe-nail was also affected. Favus would be more limited in extent, and grows under the nail in the subungual derma and soft parts. The trycophyton enters at the extremities between the layers of the nails. Both come from scratching. Eczema would also have longitudinal striae, but the nails do not separate into filaments. Psoriasis has transverse striae. The trycophyton may destroy the nails. Vidal thinks favus would require an infinite time to destroy the matrix of the nail. In onychophytosis, which results from alterations due to long irritation, eczemas, crushing, tight shoes, etc., adventitious parasites may be found, the *torula vulgaris*, for instance, being possibly present wherever vacuoles exist in epidermic products. To treat true onychomycosis the nail should be thinned by scraping with a bit of glass, and then wet frequently with corrosive sublimate, one gramme in two hundred of water, which is about three times as strong as one would use it upon the skin or hair.

SCLERODERMA ADULTORUM.

Neumann, of Karlsruhe, gives² the case of a peasant woman, aged sixty-three, who in the autumn of 1878 felt a disagreeable tightness of the skin of the right leg and thigh, the latter showing soon afterwards some thickening and a reddish-brown color. On examination, the right leg seems smaller than the left; the skin from the knee up stiffened, shining, and separated into fine longitudinal wrinkles, in parts scaly, and from the calf to the heel full of hæmorrhagic points. The skin cannot be raised, and the whole limb seems of one consistence, and that cartilaginous. The knee is bent. Sensation preserved, though no blood follows the needle. Changes of temperature are noticed by the patient. Pressure causes pain. The thigh is yellowish in front, brownish spots and bands appearing after exposure to the air; behind, it is rough and fissured, a greenish-brown crust covering a livid, bluish spot, partly hæmorrhagic, like a vascular naevus. A syringe of a two per cent. solution of pilocarpin caused profuse sweating everywhere except upon the affected limb, which remained quite dry. A piece of skin excised showed, under the microscope, unchanged epidermis and normal sebaceous glands, but a thickened corium forming a uniformly consistent tissue to the fascia, and passing into the subcutaneous cellular tissue without demarcation, and total absence of fat. Minor details proved indisputably a scleroderma, a stage of infiltration and elevation having been followed by atrophy or cicatrization, the cicatrix not being the primary symptom.

¹ Gaz. des Hôpitaux, March 9, 1880.² Virchow's Archiv, December 15, 1879.

Blood-vessels were sometimes dilated, and again at times contracted. Ætiologically, the case is negative, there being no history of rheumatic, erysipelatos, varicose, Basedow's, vaso-motor, or other affections. As to treatment, stimulant frictions, warm or alkaline baths, pilocarpin, etc., produced no effect. Possibly at an early stage these means, with hygienic conditions, might have been of service; but the present anatomically fixed condition, resulting from long continuance of the abnormal process, is not to be changed. The patient walks, although upon her toes.

SO-CALLED VIRULENT BUBOES.

Berger quotes³ a paper⁴ of Dr. Gustaf Trägårdh upon the overestimation of the virulence of chancroidal virus as compared with that of degenerated simple pus. He found, out of one hundred and fifteen sailors with buboes, fifteen affected by urethritis alone, without any chancreoids. The buboes were all alike, and inoculation from the freshly opened chancroidal buboes produced no chancreoids; while all will admit that no special "gonorrhoeal" virus is to be obtained from buboes derived from a clap. No special virus, in the latter case, is passed along to the glands and there stored up, and the writer holds that such a supposition is equally incorrect in the case of chancreoids. Where buboes had been opened before coming under his care, positive results were obtained in nearly fifty per cent. of the inoculations, and he holds that in cases where chancreoids have been inoculated from buboes, these last have themselves been changed from simple sores by indirect or direct contact with the preëxisting chancreoids. The writer has many times seen the ulceration in the groin exactly correspond to the position of the ulceration upon the penis. If the affected glands in the groin are depositories of chancroidal poison rather than simple irritation products, why are not the walls of the endothelium-lined lymph vessels affected by chancreoids? Furthermore, if a special virus can reach the first gland of the lymphatic system, why does it not also extend to the second, and so on, which fact has never yet been observed? Finally, if chancroidal virus is present, why do so few of even chancroidal buboes ever suppurate and form of their own accord open chancreoids?

CASE OF CHROMIDROSIS.

Dr. Camuset furnishes⁵ the case of an unmarried woman, twenty-one years old, anæmic, though from healthy parents; menstruating at twelve years once, then not for four years, but at present profusely; prurient and dyspeptic. The discoloration (quite black) was noticed one morning upon awaking. It was situated upon the lower eyelids, whence it extended upon the cheeks. During the following three years the breast, abdomen, and inner thighs took on the same appearance, which was better at times, and again worse, especially after the patient had slept well. Tonics and treatment for dyspepsia produced no effect, and the patient finally resorted to cosmetics.

COLLOID DEGENERATION OF THE SKIN.

Dr. Besnier reports⁶ the case of a forester, aged forty-six, the upper half of whose face and nose showed an eruption of small, yellow, shining, translucent protuberances,

³ Schmidt's Jahrb. Bd. 181, No. 12.⁴ Hosp. Tidende, 2, B. Vt. 53. 1879.⁵ Gaz. des Hôp. 98, 1879.⁶ Gaz. hebdom., 1879, No. 4.

appearing like blisters, but containing jelly rather than fluid. They were removed by the scraping-spoon. Histologically, the contents of the nodules consisted of a colloid mass seated in the upper layers of the corium. The papillae, glands, and epidermis in the neighborhood were pushed aside, and had become partially atrophied. The writer objects to the name colloid-milium proposed by Wagner for this disease, upon anatomical grounds.

NON-VENEREAL SYPHILIS.

Dr. Plummert, assistant at the clinic of Professor Pick, of Prague, gives¹ detailed accounts of four cases of primary affections of the mamma in women, and one of the breast, under the clavicle, in a man; two of the lip in women, and two in men; one of the chin in a baby boy; one of the thumb in a woman. The first four were infected by their foster-children; the fifth from his brother, by means of a scratch. The lips of the women, where affected, had, in the first case, come in contact with the plates, glasses, etc., used by a syphilitic sister; in the second case, with the sugar teat of her infected infant, and, in caressing, probably with the infant himself. The sugar teat was frequently moistened in the mouth of a syphilitic woman, a fellow-lodger, before being given to the child, the baby boy mentioned above. The men with affected lips had acted as cunnilingi. The woman whose thumb was affected had, as midwife, delivered a syphilitic woman.

HYMENOPTERA AS PARASITES IN THE SKIN.

Professor Fischer, of Breslau, records² the case of an elderly lady, well educated and not hysterical, who for six months had been afflicted by a general exanthem, especially upon the fore-arms, legs, and back. Blisters, she stated, would form, causing intolerable itching, and, being scratched open, would emit small living insects, which flew away. The husband and immediate family testified to the same effect. Still doubting, Professor Fischer induced the lady to visit a son-in-law who was a physician. This gentleman, Dr. Theodor, of Tost, observed the fact with his own eyes, and caught a female specimen, which was examined by Dr. G. Joseph, and proved to belong to the Braconidae, Hymenoptera. The case will be now most thoroughly investigated. No applications have as yet afforded relief. The hymenoptera are known to be parasitic upon rodents and caterpillars, but have not been described as attacking human beings.³

PEMPHIGOID INFLAMMATION OF THE HANDS FROM ARSENIC INTERNALLY.

The English School of Dermatology is at last finding out that arsenic is not a universal panacea in affections of the skin, especially acute ones, and Mr. Startin contributes⁴ a case of apparently bullous dermatitis, due to the internal administration of Fowler's, and later of Donovan's, solutions, in five-minim doses ter die. Both hands were freely perspiring, hot, swollen, itching, and tender. Some fever. Pulse 100. Temperature 38.5° Cent. Palmar and dorsal surfaces covered with vesicles and blebs, discrete or coalescing, entire or broken, and oozing a serous or sero-purulent fluid, which was alkaline and coagulable by heat or nitric acid. Microscope showed pus and epidermic cells.

SYPHILIS.

Dr. Schenck, in a lecture to students upon syphilis, collates⁵ some interesting facts and statistics: 1,500,000 new cases occur annually in England, Scotland, and Wales; 58,000 cases are annually treated at Guy's Hospital alone. David suffered from it. Herod died of it. Horace speaks of the *morbus caninum*, and certainly old Dr. Grimbée caught it "in the field on a summer's afternoon;" the clergy, blameless though suffering, denying that "the stars were at fault," and asserting that "it was in the air." The aetiology of its nomenclature has been supposed to suggest miscegenation, *sus* and *phileo*. Welch has shown that forty-six per cent. of patients dying from aneurism are syphilitic. Hutchinson has taught that "all living pus is contagious, and soft chancre is due to contagion with inflammatory products. If the pus contains syphilitic virus we have syphilis; if not, chancreoid." Dr. Schenck regards syphilis as an exanthem, and its so-called tertiary lesion as its sequela; urges that one, in all one's givings, give mercury; would commence treatment thus before the appearance of any symptom beyond the primary sclerosis; and desires a law, not merely to protect men from the diseases of women, but, in accordance with common sense and justice, one which shall also protect women from the diseases of men, and that without giving impunity to lust, discouraging marriage, and lowering the general moral tone.

ETIOLOGY AND PROPHYLAXIS OF PREMATURE BALDNESS.

The majority of cases of premature baldness result from seborrhoea; that is, from not using enough soap and water. But every rule has its exception. There are some skins so dry that the use of soap and water should be avoided. Over-stimulation may cause the loss of hair, though the irritants employed are those of most use in exciting sluggish follicles to the production of hair. Ellinger found⁶ that eighty-five per cent. of patients suffering from a particular kind of baldness had been in the habit of liberally washing the head from youth. Of elderly people with specially luxuriant hair growth, only eight per cent. were washers, while nearly all wore the hair loose and dried it immediately after washing. Baldness of the crown of the head he does not connect with washing, but rather with seborrhoea. It is the "frontal alopecia," where, in addition to the change in the natural direction of the growth of the hair, the parts are frequently stimulated by the water used to wash the face, which he holds is due to over-use of water, the external layer evaporating rapidly, the lower ones forming, "at the exit of the hair from its follicle, with epidermal scales and sebum, an emulsion which hardens, occludes the hair follicles, and, by stopping these up, produces atrophy of the hairs." Thorough mechanical cleansing is Dr. Ellinger's prophylaxis; not with soap, but with sand and a steel brush. His opinions had best be received *enim* *see centigrams salis*.

— We are happy to state that Dr. G. H. Lyman, president of the Massachusetts Medical Society, who has been confined to his house for some weeks by severe illness, is better, and hopes soon to be able to give his personal attention to correspondence and other business connected with the society.

Recent Literature.

A System of Medicine. Edited by J. RUSSELL REYNOLDS, M. D., F. R. S., Fellow of the Royal College of Physicians of London, etc. With numerous additions and illustrations by Henry Hartshorne, A. M., M. D., Fellow of the College of Physicians of Philadelphia, etc. In three volumes. Vol. I. General Diseases and Diseases of the Nervous System. Vol. II. Diseases of the Respiratory and Circulatory Systems. Philadelphia: Henry C. Lea. 1879.

The importance and scope of this work is well known to our readers, and through the enterprise of the American publishers we now have the somewhat bulky and expensive English edition presented in three compressed volumes instead of five, with a corresponding decrease in the cost. The text is interspersed with additions and comments by the American editor, on those subjects which the experience of American physicians has shown to present different practical aspects here; so that, in spite of the fact that many of the articles in the earlier volumes were written several years ago, as is the case in all cyclopaedic works so extensive in plan, the recent additions, combined with the standard character of the various chapters or treatises, give this system of medicine a value which no other work on English medicine possesses.

Among the contributors to Volume I., which treats of General Diseases and Diseases of the Nervous System, are Drs. Aitken, Anstie, Bastian, Begbie, Beigel, Bristowe, Buchanan, Chambers, Tilbury Fox, Gamgee, Garrod, Gee, Gull, Hartshorne, Hutchinson, Hughlings Jackson, Maudsley, Parkes, Reynolds, Ringer, Roberts, Sutton, and others of equal note.

The fatal epidemic of whooping cough which has prevailed in England this year gives emphasis to the statement by Dr. Edward Smith, in the article on that disease, that in the London district during ten years only six affections caused a greater mortality, namely: phthisis, pneumonia, bronchitis, typhus, convulsions, and scarlatina. The variable course and duration of whooping cough, the fact that it usually subsides after a longer or shorter interval, either with or without remedies, and that the most potent specifics in the hands of one practitioner may entirely fail when applied to a different class of cases by another, lead the author to regard attention to the general health, and the alleviation of the spasms as the chief desiderata, and for the latter purpose he has found the muriate or acetate of morphia, given in doses of one sixty-fourth of a grain, every four hours if necessary, for a child a year old, producing and maintaining a slight drowsiness, to be usually efficacious. The constant experimenting with newer remedies, however, shows a want of faith in the specific character of any of the old ones in this distressing malady.

To the article on Typhoid Fever, by Dr. Harley, the editor has added paragraphs on the expectant and the antipyretic modes of treatment. Professor McLean, writing on dysentery, expresses great confidence in the early use of hot baths to restore the suppressed action of the skin, and in the administration, in the early stages, of twenty-grain doses of ipecacuanha, after the method which has proved so successful in India. Dr. Garrod's valuable articles on Gout and Rheumatism are supplemented by the editor's notes on the sal-

icylic acid treatment, in which the inconvenience and possible dangers of a too free use of that drug are set forth.

The chapters on Diseases of the Brain and Nervous System, which occupy the last half of Vol. I., are of especial interest and value to the general practitioner, and are written by the best authorities on those subjects.

Vol. II. begins with a practical article on Diseases of the Larynx, by Dr. Morell Mackenzie, which concludes with an appendix on the use of the Laryngoscope. Then follow chapters on Emphysema of the Lungs, by Sir William Jenner; Asthma, by Dr. Hyde Salter; Phthisis Pulmonalis, by Dr. Bennett; Pneumonia, by Dr. Wilson Fox, and others of equal importance. The article on Pleurisy, by the late Dr. Anstie, contains a *résumé* of Dr. Bowditch's original papers on Paracentesis Thoracis, which operation is commended to the attention of British readers in language much more forcible and appreciative than had previously been adopted by writers on that subject.

The chapters on the Diseases of the Heart and Blood-Vessels, by Drs. Peacock, Sibson, Gairdner, Gowers, Begbie, Hilton Fagge, Douglas Powell, and Bristowe, are perhaps the most complete portions of the work, which is soon to be finished by the appearance of the third volume.

A review of such an extensive work is hardly practicable, but we have indicated above its general scope for the benefit of those of our readers whose attention has not been called to this important American reproduction with its essential additions.

The Spectroscope in Medicine. By CHARLES A. MACMUNN, B. A., M. D., University Dublin. Philadelphia: Lindsay and Blakiston. 1880.

This treatise, which considers the applications of the spectroscopic to medicine, and more especially to the study of blood, bile, and urine, contains but very little that may not be obtained from other sources. It is chiefly valuable in that it gives much information which otherwise must be sought for over a wide field, and on this account it will probably prove of great service to many. It contains three chromo-lithographic plates of physiological and pathological spectra, and in an appendix a complete bibliography relating to the study of absorption spectra, etc. The latter is very useful for reference.

Minor Gynecological Operations and Appliances. By J. HALLIDAY CROOM, M. D. Edinburgh: E. & S. Livingstone, 57 South Bridge. 1879.

As a simple reminder to the author's own students of the lessons he has given them, we think the book may serve its purpose, which Dr. Croom implies in the preface to be the one intended for it. But as a work to send out to the profession, it is of little value. It is beautifully printed, and contains about a hundred pages.

— We observe that Mr. Edison, not having succeeded in dispelling darkness by electricity, has consoled himself by an invention to relieve the suffering of neuralgia. It has been patented under the suggestive name of Edison's Polyform.

Medical and Surgical Journal.

THURSDAY, APRIL 29, 1880.

A Journal of Medicine, Surgery, and Allied Sciences, published weekly by Houghton, Osgood and Company, Boston. Price, 15 cents a number; \$5.00 a year, including postage.

All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.

Remittances by mail should be sent by money-order, draft, or registered letter to Houghton, Osgood and Company, Boston, Mass.

AN UNUSUAL MODE OF SUICIDE.

A YOUNG man, who, with his father, worked a small farm near Chelsea, committed suicide lately in a manner and under circumstances which deserve notice. He and his father slept in an old barn on the place Saturday night, and Sunday morning the father started to go to their home, which was at a distance, remarking to his son, who had not risen from the hay where he was lying, that he should come back Monday morning, and that in the mean time he too had better go home to the house. The young man did not appear, and on Monday when the father returned, about midday, on entering the barn he found his son lying dead on the floor of the barn, with his head completely severed from his body, or attached only by a portion of skin at the front of the neck. The decapitation had been performed by a rough sort of guillotine, which the self-ordained victim must have spent the whole day Sunday in constructing. There was reason for thinking that the deed was consummated between seven and eight o'clock Monday morning. The young man must have been unconscious, if not dead, from the effects of ether at the moment when the blade descended. We extract from a daily paper, the *Boston Herald*, a description of the guillotine as constructed, with a diagram of the apparatus:—

This machine was improvised from material found in the barn, and its plan of operation, which proved equal to all its builder expected, was as follows: Two uprights, three by four joint, twelve feet in length, extended from the floor of the lower story to the ceiling, to which they were securely spiked. The lower ends of the uprights were mortised in a solid piece of hard wood, about eight by twelve inches in size, and some three and a half feet in length. In the centre of this bed-piece was chiselled out, apparently with a very dull implement, a groove sufficiently deep and wide to admit the entrance of a man's neck. Fitting between the uprights, in an easy, sliding position, was a square piece of two-inch plank, to the lower edge of which was securely fastened the blade of a carpenter's ordinary broad axe, sharpened to a keen edge. The bottom of this slider rested upon a lever fifteen inches in length, working upon a pin secured in the left upright, and from the end of which, suspended by a cord three feet in length, was a watering-pot, which had been filled with water. On the top of the slider was a box containing fifty pounds of stone. The bottom of the watering-pot, which was an ordinary twelve or fourteen quart vessel, such as is commonly used on a farm, had been perforated with holes, so that the water might leak out and release the lever, thereby allowing the sliding block with the axe attached to fall. The axe, after being released, had a fall of six and a half feet. In order to render the uprights more firm and prevent any lateral motion, a piece of scantling was mortised in between them at about eighteen inches from the top. At the base of the uprights were two holes, through which was thrust a broom-handle, which, effectually imprisoned the neck of the victim and prevented any attempt to remove it. In front of the machine, on the floor, was a small piece of timber, about two feet long, six or seven inches wide, and some four inches thick. In the end, next to the bed-piece of the guillotine, was gouged a cavity large enough to hold about two quarts, and in it was found

about a pint of ether. This ether came directly under the nose of the victim, which rested upon the floating lid of a cigar box. On either side of this, with their ends firmly braced against the bed-piece in order to steady it, was a large box filled with stones and dirt. The following is a diagram of the apparatus:—

- AA. Upright posts of guillotine.
- B. Cross-bar uniting and holding them in place.
- C. Box weighted with stone to give blade force.
- D. The knife-slide, going up or down in the grooves on uprights.
- E. Broad-axe.
- F. Lever holding axe and weight in place.
- G. Water-pot, which, leaking, released the axe and block.
- H. Collar in which deceased placed his neck.
- I. Box in which ether was placed under nose of deceased.
- JJ. Boxes filled with stone and used to brace the uprights.
- K. Piece of broom-handle inserted in uprights over the neck to keep head in position.

This case recalls a very similar one which occurred in a town in Indiana, and may be found fully reported in the *American Practitioner* for July, 1876, from which we quote a description of the instrument as constructed on that occasion:—

The essential parts of the instrument were a broad-axe and lever screwed at one end to the floor; the axe was secured to this lever, seven feet in length, the lower two thirds of which consisted of wood, by upright pieces of bar-iron fastened with bolts and screws. The lever was composed of three separate parts, for convenience in transportation, firmly bolted together, the widened end being attached to the floor by means of hinges to prevent any possible lateral motion. At the other end of the lever, the iron bars to which the axe was attached were very heavy, in order to give the machine great effectiveness when put in motion. The axe being elevated, was sustained at the proper angle for falling the greatest distance possible by means of a double cord attached to the free end of the lever, and to a small hook in a bracket, which was securely fastened to the wood on the side of the window, about five feet from the floor. On this bracket was placed a lighted candle between the cords, which were consumed when the candle had burned sufficiently. The axe being then unsupported, fell. The suicide had placed an ordinary soap box on its side, with its open end just even with the

line where the axe would fall; this box contained his head when he lay stretched on the floor at right angles to the direction of the falling axe; three pieces of pine board sustained his neck; the chin was held back and the head kept in place by a little wooden rod falling through the sides and across the box. The body and legs were fastened to the floor by means of straps.

The suicide had provided himself with an anæsthetic; but it is questionable whether the quantity or method of administration were such as to cause unconsciousness.

The arrangements in this case were marked by the same deliberation and determination as in the other. The suicide came to a hotel Saturday morning, selected his room, made his preparations during the day, paid some visits, during which he was cheerful and talkative, returned to his room about eight in the evening, and was found the next day decapitated. Both of these men were of good habits, as reported, and happy and prosperous in their domestic and social relations. The Indiana man was said to have always shown a great interest in methods of causing death, and much admiration for men who have rendered themselves famous as inventors of machines which would cause death suddenly and with dispatch. Of the Chelsea man, too, his acquaintances report that his conversation was mainly upon criminal matters and suicides, and that he was full of information on all such subjects. One of them was a man of remarkably fine physique, and the other by no means the reverse. In regard to the Indiana case no family history was given, but in the Chelsea case the hereditary taint was extremely probable, both grandparents on the father's side having been confined in insane asylums, the grandmother dying in one. In the former case the choice of surroundings seems to indicate a morbid desire for notoriety as the influential motive; in the latter a letter was left, addressed to the family of the suicide, saying he considered the step he was about to take the only right one, and that he would therefore offer neither regrets nor excuses. There was no theatrical display.

The precision with which the fatal work was accomplished in each case might serve as an example to official executioners, who sometimes make sadly bungling work, of which we were reminded not long ago in two neighboring States, and suggests anew the question by which method society would in the long run be the gainer and the tendency to crime diminished,—by a frequent painless execution of the death penalty, or a more rare and terrifying one.

SPECULATION IN OPIUM.

A WRITER in one of the New York daily papers calls attention to the fact that there is now likely to be a "corner" in opium, gotten up for speculative purposes. For some weeks past, he says, it has become evident that the supply of medicinal opium would fall short of the actual public requirements. It seems that the supply for the last two years has been five thousand to six thousand cases, of one hundred and fifty pounds each on the average; but last year the production fell off to about four thousand cases, and the estimate of the coming crop is reduced to about fifteen hundred or two thousand cases, owing,

it is stated, to the unusually cold weather that has prevailed in Turkish Asia. The annual consumption is about five thousand cases, and had it not been for the extraordinarily large crop in 1877-78, which amounted to nearly ten thousand cases, the scarcity of the drug would have been felt during the current year. This unusual surplus, however, is now exhausted, and the visibly supply is reduced to about four thousand cases, distributed between London, Smyrna, and New York, of which it is estimated that at least one thousand cases are unfit for use. Such being the statistical phase of the supply and demand of opium, it is not perhaps surprising to learn that Wall Street, aided by some London speculators, has gobbled up nearly all the available opium in the United States, and that the price has already gone up from \$1.00 or \$1.50 a pound in bond to \$6.50 or \$7.00. Opium being an article that the public cannot dispense with, it seems altogether probable that during the present year it will rise to at least ten or twelve dollars, thus recalling the days of a dozen years ago, when the small supply of the drug was controlled by a few men, and it was sold in jobbing lots as high as thirty dollars a pound. There can certainly be no doubt, if the above statistics are correct and the short crop of opium in Turkey is a fact, that the speculators will have it all their own way, because our own trade cannot look to Europe for a renewed supply, on account of the scarcity of the drug there as well as here.

But the Wall Street men are not the only ones who are now hoping to grow rich off the necessities of suffering humanity. The wholesale druggists are also very largely interested in this disgraceful and iniquitous scheme of speculation, and the coolness and freedom with which they speak of the unscrupulous operations in which their insatiable greed induces them to engage affords a melancholy commentary on the boasted civilization and enlightenment, to say nothing of the Christian spirit, of the age. The situation is described by a member of one of the firms as follows: The stock of medicinal opium in the world to-day is estimated to be about four thousand cases, seventeen hundred of which are in the United States and thirteen hundred in London. Two months ago a syndicate of capitalists began to buy up and concentrate the stock. Probably they now control two thousand cases,—or half the entire stock in the world,—and they have concentrated it in New York and London. The average annual consumption of opium in the world is from five thousand to six thousand cases, and the coming crop from Turkey will be three thousand cases (a considerably higher estimate, it will be noticed, than that of the writer mentioned above). The syndicate unquestionably has a very long purse, it being probable that there are at least fifty million dollars at its back. "If you want to buy any opium," the gentleman remarks in conclusion, "you must go to Wall Street or come to us. They would like to have us come in with them, but we prefer to row our own boat."

Probably the only consolation that can be derived

from a consideration of this opium "boom" is that the price of the drug is not likely to reach the extreme high figures that it did twelve years ago, partly because the stock is not so low in quantity as it was then (the entire supply of the world being reduced, it is said, to sixteen hundred cases), and partly because the duty on importation was then \$2.50 per pound instead of one dollar, as at present.

THE WARREN PRIZE.

WE are authorized to announce that none of the essays offered this year for the triennial prize have been found worthy of an award. We are also able to state that one of the causes operating to lower the standard of the work offered for competition was the lack of a reasonable amount of care in the preparation of the manuscript. This is, we believe, a crying complaint of prize committees. Few writers appreciate the labor necessary to read and estimate articles under even the most favorable conditions. If an author sets any value upon his own work, he should at least confer upon it the honor of being copied and bound in a form that will make handling a possibility. If the writer shows little respect for his work, he can hardly hope to exact it from others. That an author should preserve his incognito goes without saying, and yet these rules are in a great number of instances ignored.

The Warren prize is the largest offered in this country for general competition. The subject for 1883 will, we understand, be announced shortly.

MEDICAL NOTES.

— We call attention to the advertisement of the committee of arrangements of the Massachusetts Medical Society with regard to the exhibition of drugs, instruments, and books at the annual meeting in June.

— A cottage hospital containing twelve beds was opened with appropriate ceremonies on the 20th inst. in the city of Auburn, N. Y.

— Dr. Joseph Rogers writes to the *British Medical Journal*, "In the *London Medical Record*, which frequently contains useful hints for the general practitioner, I saw lately a formula for the treatment of post-nasal catarrh. It was, I believe, originally suggested by Dr. Duffin. It consists of oxide of bismuth, powdered gum acacia, and a small quantity of muriate of morphia. This should be well mixed, and then, if used as a snuff in severe coryza or post-nasal catarrh, it acts in a most charming manner. Cases of great severity and long duration have yielded to it after three or four days."

— The *Maryland Medical Journal* says, "Listerism, pure and simple, it is stated, is dying out in New York city. It is employed in New York and Roosevelt hospitals by only one surgeon. It is but little used in Bellevue, Presbyterian, St. Luke's, and St. Francis hospitals. At the Woman's Hospital it is applied as a rule in ovariectomy, but not always. In Baltimore it

has never been generally employed, its use being confined to one or two test cases. This is due to the great inconvenience attending the use of the spray, and to the fact that thorough cleansing and drainage have been considered the only essential results secured by these methods, being as good as those effected by the employment of Listerism in all of its details."

— The *Chicago Medical Gazette* says with regard to unusually high temperatures: Dr. John W. Teale, of Scarborough, England, our readers will perhaps remember, published a very notable case of extreme high temperature in 1875, which was the subject of considerable criticism at the time. The temperature of the patient, who was suffering from a severe spinal injury, ranged as high as 122° F.; the observations were made with unusual care and confirmed by two observers. The patient recovered, but subsequently had a relapse under another physician, and the same peculiarities were noticed, a thermometer bursting on one occasion at 117° F., the index being found in the broken-off air-space at the top. At the meeting of the British Medical Association at Cork, last summer, a paper on the subject was read by Dr. Donkin, of London, and published in the *British Medical Journal* of December 20, 1879. In it he reports an observation of his own of a case of enteric fever in which the temperature ranged as high as 111.6° F., and also refers to seven other cases observed by competent medical men, in which it was even higher. In none of these were specially dangerous symptoms or conditions mentioned as apparently connected with these high temperatures. On the strength of this Dr. Teale again comes to the front in a communication to the *British Medical Journal* of January 24th, in which he claims that his observations have been fully vindicated, and that the following points are clearly established: (1.) "Temperatures above the degree formerly supposed to be necessarily fatal do sometimes occur without a fatal issue; nay, even without extreme peril to life. (2.) Such exceptional and excessive temperatures as a rule end in recovery. (3.) The conditions of body in these cases of excessive temperature appear to be distinct from the conditions existing in fevers, in which the rule as to the extreme peril of temperatures of 107° F. and upward remains unassailed."

NEW YORK.

— Dr. Salvatore Caro, who some time ago brought suit against the Metropolitan Elevated Railroad, in order to recover damages for the injury done him by the running of the road in front of his residence on Fifty-Third Street, has had a decision rendered in his favor by the superior court. In his complaint he referred to the noise of the trains, the obstruction of light, the offensive odors arising, and the fouling of the air by noxious gases, detrimental to the inmates of the house, and stated that he would never have bought his lot nor built his house in that street had he known that he would be subjected to such a nuisance. The company demurred to the complaint, and the referee in the matter sustained the demurrer. Some months ago the case was argued on appeal by

eminent counsel on each side, and on the 5th of April Chief Justice Curtis announced that the judgment was reversed, two written opinions being read in favor of the decision, that of Judge Speir, and a concurring one by the chief justice. Judge Speir concludes his opinion as follows: "No one will question the utility of the elevated railroad as a public improvement of great convenience and accommodation to the city and the public at large, but these accommodations cannot authorize or justify its invasions on the rights of any portion of our citizens. The individual whose property is affected because the road is of great public value should be indemnified and fully compensated by the public or by the company which profits by the improvement for any loss or damage he has or may sustain. . . . The defendant admits the injury and wrongs done to the plaintiff, as alleged in his complaint, and its want of ability to make reparation. We are of opinion that the appellant is entitled to relief, and that the judgment should be reversed, with costs." This, it seems, however, is not the end of the case, as it is now to be carried to the court of appeals.

—At a meeting of the Medico-Legal Society, held April 7th, Dr. William A. Hammond read a paper on general paralysis of the insane, with special reference to the case of one Abraham Gosling, which has lately been before the courts, and which has attracted a good deal of attention on the part of the public. During the course of it he stated that he was perfectly willing to stake his medical reputation on this case, and that if Gosling were alive in three years he would burn his diploma and retire from the profession. In the discussion which followed the paper two physicians who were employed as experts on the opposite side of the case combated Dr. Hammond's views, and attempted to prove the entire absence of the symptoms of general paralysis, and the perfect sanity of the patient.

—At the last meeting of the society, April 14th, the evening was principally taken up with a discussion of a paper, previously read by Dr. George M. Beard, on The Problems of Insanity, Dr. Beard bringing the debate to a close with some remarks in which he also discussed the Gosling case.

—On the 2d of April the first of a series of free popular lectures, by physicians, at the Young Men's Christian Association was given by Dr. Willard Parker, Jr., on Good Health and How to Keep It. The second, on The Skin in Health and Disease, was given by Dr. L. Duncan Bulkley on the 9th, and the third on Some of the Relations between the Physical Organism and the Moral Nature, by Dr. Fessenden, on the 16th. The remaining three will be by Drs. Bosworth, Kelsey, and William H. Thomson, their subjects being respectively, What is a Cold, and How is It Contracted? The Bowels and the Care of Them, and Psychological Relations of the Will.

—At the recent Brinley sale of rare old books, some of the works of Cadwallader Colden, the medical lieutenant-governor of New York, brought very high prices. His *Explication of the First Causes of Action in Matter, and of the Cause of Gravitation*, brought

\$112.50, and his *History of the Five Indian Nations Depending on the Promise of New York*, printed by Bradford, in 1727, brought \$330, while his *Papers Relating to an Act of the Assembly of the Province of New York*, printed by Bradford, in 1724, sold for no less than \$685. It was purchased by Mr. Moore for the Lenox Library.

—The commissioners of charities and correction have made several changes in the medical staffs of the public insane asylums of the city, the principal of which are the following: Dr. A. E. MacDonald, superintendent of the asylum on Ward's Island, who, several months ago, on the removal of Dr. Strew, was placed in charge of the one on Blackwell's Island in addition, has been relieved from the latter, and Dr. Franklin, who for some time has had the management of the branch institution on Hart's Island, has been appointed permanent superintendent of the Blackwell's Island asylum, while Dr. Healy, who has been assistant physician there, will succeed Dr. Franklin as chief of staff at the Hart's Island asylum.

ST. LOUIS.

—It is again our painful duty to announce the death of a prominent physician of St. Louis. On the 27th of March, 1880, at Hot Springs, Arkansas, Dr. John James McDowell departed this life. He was the son of Dr. Joseph Nash McDowell, the founder of the Missouri Medical College, the first medical college west of the Mississippi River. He was a nephew of Dr. Daniel Drake, of Cincinnati, and grandnephew of Dr. Ephraim McDowell, the originator of ovariectomy. From 1855 to 1861 he was demonstrator of anatomy in the Missouri Medical College, and from 1864 to 1873 was demonstrator of anatomy in the St. Louis Medical College. In 1873 he was unanimously chosen professor of anatomy in the latter institution, which position he held till the time of his death. He was most sincerely loved by the large circle of his professional acquaintances and by his patients. St. Louis, and especially the St. Louis Medical College, have met with a truly great loss in his death. Appropriate memorial resolutions were adopted by the St. Louis Medical Society.

—The February meeting of the St. Louis Obstetrical and Gynecological Society discussed Dr. S. G. Moses' paper on post-partum hemorrhage, reported in the *JOURNAL*, April 1st. Dr. George G. Engelmann indorsed the views expressed in Dr. Moses' paper, and in addition recommended in desperate cases swabbing out the uterus with cotton balls steeped in a solution of the perchloride of iron, "thus causing mechanical irritation, bringing the iron in contact with all the parts, and at the same time removing the dangerous coagula." He had used this method and seen it used a number of times where it had answered admirably, and he regarded it as much safer than the injections usually recommended. He objected to the injections of solutions of iron, because they form clots which remain in the womb, and about the third day begin to putrefy and disintegrate, and thus expose the patient to septicæmia. He regarded the free use of

ergot as dangerous, as being liable to produce prostration and weakness. In great prostration following post partum hemorrhage he recommended the hypodermic injection of ether, not upon his own experience, but upon that of Dr. Chadwick, of Boston.

Dr. Gehring thought that cases of great prostration depending on a relaxed condition of the uterus remedied by the use of ether could be explained in the following manner. The excited condition of the nervous centres prevented their concentrating their energies on the uterus, and it remained relaxed; but the effect of the ether was to quiet the nervous centres, and thus to allow them to act upon the uterus without any disturbing influence coming in to divert them.

Dr. Moses, in corroboration of this theory, said that in prostration from other causes he had used hypodermic injections of ether without the benefit he had expected.

The use of nitrite of amyl, hot-water applications to the head and to the spine, and hot-water injections into the vagina were also spoken highly of as means of treating post-partum hemorrhage.

Dr. Gannall reported a case of trismus nascentium, treated with minute doses of bromide of potassium and chloral, in which recovery occurred.

Disclaim.

THE INHALATION OF ETHYL IODIDE FOR THE RELIEF OF DYSPNOEA.¹

BY ROBERT M. LAWRENCE, M. D.

AMONG the agents whose use by inhalation has been recommended for the relief of certain forms of dyspnoea, there is one — the iodide of ethyl or hydriodic ether² — which has been but little used in this country, but which appears to possess merits entitling it to a fair trial. As early as the year 1850 experiments were made by M. Huette,³ with a view to testing its therapeutic value. After this it seems to have been for a long period quite forgotten, until attention was directed to it by Professor Sée⁴ in 1878, in a report of twenty-four cases of asthma successfully treated by iodide of potassium and iodide of ethyl. After a series of observations extending over several years he thus summarizes his conclusions: "Ethyl iodide cures the paroxysms of asthmatic dyspnoea very speedily, and appears to present advantages as a remedy in cardiac, and even in laryngeal, dyspnoea." Dr. Thorowgood⁵ has also reported beneficial results from its use in the treatment of several cases of asthma at the Victoria Park Hospital.

It may be administered by pouring a few drops on a piece of linen; or, where a stronger effect is desired, inhalation may be directly from the vial, care being taken to allow a sufficient admixture of air. Its physiological effects, when thus employed for purposes of experiments, are those of a mild exhilarant. It strengthens the pulse, increases the appetite, and invigorates the

functions generally, and particularly that of respiration. After frequent prolonged inhalations, repeated for ten and fifteen minutes, I have experienced no ill result except a slight degree of dizziness. By means of the chloroform and starch tests, I have found iodine in urine voided at the following intervals after the inhalations: Forty-five minutes, one, seven, eighteen, twenty-four, and thirty hours. Before and after these limits its presence in the urine was not detected.

The rationale of its action appears to be as follows: In certain cases, as in the reflex variety of nervous asthma, ethyl iodide may relieve dyspnoea by lessening excitomotor action. In the dyspnoea of bronchitis complicating asthma, it not only relaxes bronchial spasm, but, by virtue of its iodine, promotes free mucous secretion. In other chronic affections of the air-passages, it may relieve embarrassed respiration in one or both of these ways. Its action is therefore partly antispasmodic and partly expectorant and alterative. Inhalations of ten minutes each twice daily, may be prescribed. It should be borne in mind that failure to obtain the best results in a given case may be due to individual idiosyncrasy. A hasty judgment on the merits of the drug, after a single trial, is therefore to be deprecated.

CASE I. Katharine N., aged fifty, short and of slender build, unmarried, tailoress, first came under the writer's care at the Boston Dispensary, in October, 1876. She had been a martyr to asthma and chronic bronchitis for twelve years. Frequent paroxysms of dyspnoea had greatly reduced her strength, and her sufferings were unusually severe. During the next two years trial was made of nearly every known remedy, but without much benefit. Tonics and alteratives seemed of no avail.

The nitrite of amyl gave some relief, but was dreaded by the patient on account of its disagreeable physiological effects. In February, 1879, trial was made of ethyl iodide. The result was remarkable. Not only was the dyspnoea relieved, but there was no recurrence of it for several hours, and a good night's rest was obtained. Similar favorable results have followed each inhalation. At the present time, April, 1880, the attacks of dyspnoea are few and far between, and much less severe than formerly.

CASE II. James B., aged fifty-six, slender-built indoor man, contracted spasmodic asthma in the army in 1865, and has been subject to it ever since. He had attacks of dyspnoea frequently in the early morning. Has tried most of the usual remedies. In February, 1879, began inhaling ethyl iodide, and found that it gave positive relief. When used at the commencement of a paroxysm, it had the effect of rendering the latter abortive. A decided amelioration of symptoms followed its continued use.

CASE III. Thomas A., aged fifty-seven, plasterer, has had nervous asthma for sixteen years. It first supervened on an attack of bronchitis. Paroxysms of dyspnoea were frequent, and lasted some hours. Was obliged to sit up at night. After trial of different remedies, began inhaling ethyl iodide February 14, 1879. Marked relief followed. After several weeks of this treatment, the paroxysms, which had steadily diminished in number, at length ceased altogether.

April 16, 1880. Patient has been free from dyspnoea for a year past, though his respiration is still wheezy.

In several other cases I have employed this treatment for the relief of dyspnoea, and in almost every

¹ Abstract of a paper read at the annual meeting of the Suffolk District Medical Society, April 24, 1880.

² Dr. J. F. Oliver has lately prescribed a syrup of hydriodic acid in the treatment of asthma with excellent results.

one with excellent effect. If others shall be induced to give it a trial my object in reporting these cases will be attained.

REMARKABLE RESUSCITATION.

In the *Medical Record* Dr. W. E. Forest gives these details of his successful treatment of a case of prolonged asphyxia in a newly born child:—

"The child was placed in a sitting posture upon blankets before the fire. My hand was placed behind the head and thorax of the child, and its body leaned backward so that it rested upon this hand. The hands of the child were carried as far as possible above its head by my left hand. By this the ribs and shoulders were raised, while the head was thrown backward, thus expanding the thorax and drawing air into the lungs. The second movement was to lower the arms of the child so that they fell by its side, while my hand, still retaining those of the child in its grasp, rested against the front of the child's thorax and head. The third movement was to lean the child forward and press suddenly downward upon its shoulders, at the same time that the hand in front pressed the ribs inward. This method, which is somewhat difficult to describe, but easy to carry out, caused the first certain expulsion of air from the child's lungs (and a consequent refilling of them), for the air could be heard bubbling out through the nose and mouth of the child. Then the lungs were refilled by the first movement. Still this respiration was entirely involuntary on the part of the child, and ten minutes' persistent effort by this method gave no sign of returning animation. Nearly three quarters of an hour had now elapsed since the birth of the child, and meantime the child's skin began to feel cold and clammy. On account of the coldness of the child I determined to use external heat in conjunction with artificial respiration. I called for a deep bowl partly filled with water, at a temperature of about 112°. I placed the child in the bowl in a sitting posture, so that the water came up to the child's diaphragm when its body was in what I have called the 'first position' in the last method of artificial respiration.

"Then the artificial respiration was kept up according to this method, while the child's body was partly immersed in hot water. After a few minutes I was astonished at the child showing a little color in its cheeks, and then making its first spasmodic effort at inspiration. Fully five minutes elapsed before it made another gasp, but gradually its efforts became more frequent, and at the end of an hour and three quarters from the time of its birth I ventured to cease artificial respiration. The child was then breathing rapidly with a shallow, gasping respiration. I ordered it to be rolled in blankets, without being dressed, and placed in bed with its mother. Two hours later its breathing was stronger, but still shallow. The following day it appeared as strong as any child, and since then has grown rapidly."

HYDRATE OF CHLORAL.

Dr. H. H. KANE, of New York city, specially requests members of the profession with any experience whatever in the use of the hydrate of chloral to answer the following questions, and give any information they

may possess with reference to the literature of the subject:—

- (1.) What is your usual commencing dose?
- (2.) What is the largest amount you have administered at one dose, and the largest amount in twenty-four hours?
- (3.) In what diseases have you used it (by the mouth, rectum, or hypodermically), and with what results?
- (4.) Have you known it to affect the sight?
- (5.) Have you ever seen cutaneous eruptions produced by it?
- (6.) Have you known it to affect the sexual organs? If so, how?
- (7.) Do you know of any instances where death resulted from or was attributed to its use? If so, please give full particulars as to disease for which given; condition of pulse, pupils, respiration, and temperature; manner of death; condition of heart, lungs, and kidneys; general condition, age, temperament, employment, etc. If an autopsy was held, please state the condition there found.

(8.) Have you seen any peculiar manifestations from chloral, as tetanus, convulsions, or delirium?

(9.) Do you know of any cases of the chloral habit? If so, please state the amount used, the disease for which the drug was originally administered, the person's temperament, and the present condition of the patient, with reference to the state of body and mind in general, and of the various organs and systems in particular.

Physicians are earnestly requested to answer the above questions *fully*, especially 7 and 9, in order that the resulting statistics may be as valuable as possible.

All communications will be considered strictly confidential, the writer's name not being used when a request to that effect is made. Address all letters to Dr. H. H. Kane, 191 West 10th Street, New York city.

CULTIVATION OF THE CINCHONA-TREE IN CALIFORNIA.

THE *Pacific Medical and Surgical Journal* writes on the cinchona-tree as follows: "There is no subject on which our legislature could act with so much benefit to the Pacific coast as in the adoption of measures for introducing the growth of the cinchona-tree. We are more and more convinced, from all we read of its introduction and cultivation elsewhere, that there are many sections of country in our State in which it would flourish and prove a source of bountiful revenue. The latest evidence of this which we have met with is in a communication to the department of agriculture at Washington from Willis Weaver, written at Bogota, South America. Mr. Weaver has studied the habits and history of the tree, which, he says, seeks a soil inclining to dryness, but well watered during a portion of the year. We copy from his letter a few passages, which may be found in the *Scientific American* for February 28th:—

"The coasts of Northern California and Oregon would fulfill the conditions as to moisture; the slopes, of the mountains would probably furnish hilly ground very similar to that occupied by the tree in its native habitat; while I believe that the temperature would admit of its cultivation even north of the mouth of the Columbia. It is also uncertain as to how far any undue dryness of the atmosphere may be overcome by

irrigation. The surprising results already attained in the cultivation of the trees prepare us to expect further advances, and this may be one of them as naturally as anything else.

"It is well known that the barks produced under cultivation are much superior to the natural bark, as the process of mossing the tree causes a remarkable development of the alkaloids in which their virtue consists; also, that the cultivated trees are not destroyed. A strip is taken off reaching the length of the trunk and one third its circumference. The wound is then dressed with straw matting, and kept wet until the bark forms anew. The next year another strip is taken, and so on indefinitely. I am told that the harvest begins when the tree is five years old, but am not in a position to verify the statement.

"I have calculated roughly, according to the prices of land and labor here, that a plantation of a hundred acres might be put in at less than \$1000 an acre, covering all outlay, or, say, \$1500 to cover interest and all contingencies. A yield of \$8000 an acre has been reported from Indian plantations."

OBESITY.

"No doubt," says the *London Lancet*, "it is unpleasant to be excessively obese; but the morbid dread of fat which has in recent years become fashionable has no foundation in physiological fact. Fat answers two purposes: it acts as a non-conducting envelope for the body and protects it from too rapid loss of heat, and it serves as a store of fuel. In the course of exhausting diseases it not unfrequently happens that the life of a patient may be prolonged until the reserve of fat is exhausted, and then he dies of inanition. Fats supply the material of the heating process upon which vitality mainly depends. In great excess it is inconvenient; but the external layings-on of fat is no certain measure of the internal development of adipose tissue. Much less does a tendency to grow fat imply or even suggest a tendency to what is known as 'fatty degeneration.' It is time to speak out on this point, as the most absurd notions seem to prevail. Again, it is *not* true that special forms of food determine fat. That is an old and exploded notion. Some organisms will make fat let them be fed upon the leanest and scantiest and least saccharine descriptions of food, while others will not be 'fattened' let them feed on the most 'fattening' of diets. The matter is one in regard to which it is supremely desirable and politic to be *natural*, adapting the food taken to the requirements of health rather than substance. Simple food, sufficient exercise, regular habits, with moderation in the use of stimulants, compose the maxim of a safe and healthy way of life."

LISTERISM IN INDIA.

THE *Indian Medical Gazette* (February 2d), noticing the welcome fact that antiseptic surgery has "at length won for itself more than tolerance in London," adding that "this measure of recognition will, we feel assured, ere long be followed by its final triumph and all but universal adoption," offers the strongest possible testimony in its favor, founded on the experience of its employment in Calcutta. "We have long held, from

personal observation and experience, that Listerism constitutes an immense improvement in surgery and a great boon to humanity, and in the principal surgical hospital of this city a signal illustration of this truth has been given. Under surgeons of singular eminence and skill, the results of surgery in the Medical College Hospital were, not many years back, — to use a mild term, — most discouraging. Gangrenous cellulitis and osteitis, septicæmia, pyæmia, and the worst forms of erysipelas followed almost every entry of instruments into the tissues. The hospital was blamed, and nothing short of its demolition and the building of a new hospital on a better site and improved principles would, it was held, prove of any avail. Now wounds and sores heal kindly and operations succeed, patients recover in a manner eminently satisfactory, and hospitalism has almost vanished. No great change in hospital arrangements has taken place; diet and stimulants have been less liberal than in those days. The improvement is entirely due to antiseptic surgery, and the more closely Listerism has been followed the better the results. The time has now come when the system should be adopted in its purity and totality in every hospital in India. It is capable of effecting a great saving of suffering and life, and the additional expense caused by it is, under careful management, by no means formidable."

A DISPENSARY IN CABUL.

THE *Calcutta Pioneer* says: "After the capture of Cabul, in October, it was found that there was a vast amount of disease and suffering among the poorer inhabitants of the city, and that native surgery never attempted to cope with these except in the rudest way. Sir F. Roberts therefore ordered a charitable dispensary and hospital to be opened in Cabul, and Dr. Owen, staff surgeon, was placed in charge of the institution. The Kotwal's house, vacant by reason of the execution of that official for complicity in the massacre, was turned into a hospital, and work was begun at once. The rooms were cleaned and put in order, wards for men and women arranged, the tottering walls, shaken by an earthquake, made safe and sound, and then patients were invited to attend. On November 21st, Dr. Owen was first consulted, twelve wretched beings, suffering from various ailments, coming to him for treatment. They were all carefully treated; and although, on account of the scarcity of English drugs in camp, no elaborate prescriptions could be made up, the best bazaar medicines were freely given. The news of the Sirca's latest eccentricity soon began to spread throughout Cabul, and for several days the place was visited by little crowds of persons, who were either sick, or had sick friends who needed treatment. With the suspicion always at work in Afghan minds, that every act of the stranger has some obscure tendency to harm them, the citizens were full of mistrust. They could not appreciate the generosity of their conquerors, and argued that it was absurd to suppose that men who had come to destroy Cabul would sink their ideas of vengeance, and, instead of taking life, would save life and make it worth living. Gradually their ideas changed; they believed in the disinterestedness of the English *hakem*, and the number of patients increased; but no women were permitted to seek relief.

Eventually, however, some women also were found waiting at the hospital doors. A room was set apart for them; a middle-aged woman, a Cabulee, acted as matron, and reassured them when their fears overcame their desire to be made whole. By December 11th, the daily attendance had risen to 118, of whom fully two thirds were women; and Dr. Owen's services were sought after by well-to-do citizens, in whose zenanas were sick wives or favorite concubines pining under mysterious ailments. Just when attendances were daily growing more numerous came the rush of Mahomed Jan's host upon Cabul. The city was occupied, and, in the stupid madness which prompted the Ghazi to destroy all marks of our occupation, the dispensary was looted and partly wrecked. Fortunately, the few cases of instruments which Dr. Owen had to leave behind were taken away by one of the attendants, and buried in a neighboring house. But the bottles of medicines still on the shelves were broken; chairs, tables, and partitions smashed to pieces; and even

doors and windows pulled out. This was in the outer court-yard of the late Kotwal house; the rooms grouped about the inner yard were not much interfered with, as they bore but few signs of the stranger's hand. When, on Christmas Day, Dr. Owen once more visited the place, nothing but empty rooms greeted him, and so filthy that they could scarcely be entered. However, those in the outer court-yard were soon cleaned, and on the following morning patients were again found waiting at the doors. . . . Dr. Owen is now freely admitted even to houses where Afghan exclusiveness is most severe, and thus imperceptibly an influence is being gained over the minds of the people which cannot fail to do great good. The jealousy of Mahomedaus where the women are concerned is quite dismissed when they see how entirely devoted our English surgeon is to his profession, and how little it affects him whether his patients are street-beggars, in the lowest depths of misery, or ladies of the zenana, surrounded with every comfort."

REPORTED MORTALITY FOR THE WEEK ENDING APRIL 17, 1880.

Cities.	Population estimated for July, 1879.	Reported Deaths in each.	Deaths under Five Years.	Percentage of total Deaths from				
				The Principal "Zymotic" Diseases.	Lung Diseases.	Diphtheria and Croup.	Scarlet Fever.	Typhoid Fever.

Two thousand seven hundred and thirty-nine deaths were reported; 1118 under five years of age: principal "zymotic" diseases (small-pox, measles, diphtheria and croup, diarrhoeal diseases, whooping-cough, erysipelas and fever) 444, lung diseases 416, consumption 385, diphtheria and croup 142, scarlet fever 70, measles 56, typhoid fever 49, whooping-cough 34, diarrhoeal diseases 28, malarial fevers 26, cerebro-spinal meningitis 17, erysipelas 15, small-pox six, typhus fever one. From

measles, New York 18, Brooklyn nine, Philadelphia six, Chicago and Pittsburgh five, New Orleans four, St. Louis three, Cincinnati two, New Haven, Lawrence, Fitchburg, and Worcester one. From whooping-cough, New York six, Boston five, Brooklyn, Cincinnati, and Pittsburgh four, St. Louis, Baltimore, and New Orleans two, Chicago, District of Columbia, Milwaukee, Brookline, and Palmer one. From malarial fevers, New York 12, Brooklyn five, New Orleans four, St. Louis and Balti-

more two, Springfield one. From *cerebro-spinal meningitis*, New York six, Chicago, Milwaukee, and Fall River two, St. Louis, Baltimore, Cleveland, Worcester, and Springfield one. From *erysipelas*, New York four, Boston three, Brooklyn, Chicago, and St. Louis two, Baltimore and Buffalo one. From *small-pox*, Philadelphia and Chicago three. From *typhus fever*, Lawrence one.

One hundred and forty-one cases of measles, 28 of scarlet fever, 24 of diphtheria, five of whooping-cough, and five of typhoid fever were reported in Brooklyn; diphtheria 27, scarlet fever six, in Boston; diphtheria seven, scarlet fever six, cerebro-spinal meningitis six, in Milwaukee; scarlet fever 33, diphtheria 10, measles four, typhoid fever one, in Providence; diphtheria three, in Cambridge; scarlet fever 12, diphtheria eight, in New Bedford.

The total number of deaths reported was somewhat increased over that for the previous week; the deaths under five increased in a still larger proportion. Lung diseases and pulmonary consumption about the same. Principal "zymotic" diseases slightly increased. Typhoid fever continues to prevail in Pittsburgh. An increase of scarlet fever in Providence. Three deaths from small-pox in Chicago, and the same in Philadelphia. In 3 cities and towns of Massachusetts, with an estimated population of 989,650 (population of the State about 1,690,000), the total death-rate was 22.66 against 22.89 and 20.89 of the previous two weeks.

For the week ending March 27th, in 148 German cities and towns, with an estimated population of 7,688,299, the death-rate was 28.9 against 27.6 and 26.9 for the two previous weeks. Five thousand five hundred and ninety deaths were reported; 2044

under five: pulmonary consumption 659, acute diseases of the respiratory organs 579, diphtheria and croup 176, scarlet fever 75, whooping-cough 74, measles and *röteln* 62, typhoid fever 50, puerperal fever 26, typhus fever (Frankfurt a. M., Danzig, Thorn, Posen, Königsbütte, Berlin) eight, small-pox (Danzig, Königsbütte, Ratibor, Görlich) four. The death-rates ranged from 19.1 in Darmstadt to 40 in Elberfeld; Königsberg 32.8; Breslau 33.9; München 37.8; Dresden 25.3; Berlin 27.3; Leipzig 26.5; Hamburg 27; Hanover 27; Bremen 29.3; Cologne 26.1; Frankfurt 25.6; Strassburg 32.7. For the same week, Vienna 31.8, — small-pox and scarlet fever diminishing; Paris 32.2, — small-pox and diphtheria prevalent.

For the week ending April 3d, in the 20 English cities, with an estimated population of 7,499,468, the death-rate was 24.9. Three thousand five hundred and seventy-eight deaths were reported: acute diseases of the respiratory organs 395, whooping-cough 215, scarlet fever 119, measles 107, diarrhoea 34, fever 28, diphtheria 19, small-pox nine. The death-rates ranged from 14 in Portsmouth to 36 in Nottingham; London 25; Bristol 23; Birmingham 24; Liverpool 27; Manchester 32. In Edinburgh 27, Glasgow 28, Dublin 43. In the 20 chief towns in Switzerland, population 445,790, there were 46 deaths from acute diseases of the respiratory organs, diarrhoeal diseases 18, diphtheria and croup 11, whooping-cough 11, typhoid fever six, scarlet fever two. Death-rate of Geneva 29.5, of Zurich 38.2, Basle 41.8, Bern 30.7.

The meteorological record for the week in Boston was as follows: —

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U. S. ARMY, FROM APRIL 17, 1880, TO APRIL 23, 1880.

HALL, J. D., captain and assistant surgeon. Assigned to duty as post surgeon at Fort Randall, Dakota Territory. S. O. 42, Department of Dakota, April 13, 1880.

WINNE, C. K., captain and assistant surgeon. When relieved by Assistant Surgeon Corbuser, to comply with paragraph 1, S. O. 74, C. S., A. G. O. S. O. 32, Department of the Platte, April 13, 1880.

MERRILL, J. C., first lieutenant and assistant surgeon. Relieved from duty at Fort Shaw, Montana Territory, and assigned to duty as post surgeon at Fort Custer, Montana Territory, relieving Assistant Surgeon L. S. Tesson, to enable him to comply with S. O. 74, C. S., A. G. O. S. O. 42, C. S., Department of Dakota.

CORBUSER, W. H., first lieutenant and assistant surgeon. Relieved from duty at Camp Sheridan and assigned to duty at Fort Washakie, Wyoming Territory. S. O. 32, C. S., Department of the Platte.

So much of paragraph 1, S. O. 74, April 3, 1880, from A. G. O., as relates to Assistant Surgeon Meacham is revoked, and as relates to Assistant Surgeon W. C. Shannon is suspended until October 1, 1880. S. O. 87, A. G. O., April 20, 1880.

BOSTON SOCIETY FOR MEDICAL OBSERVATION. — The regular semi-annual meeting will be held on Monday next, at the hall of the Medical Library Association, 19 Boylston Place. Reader, Dr. H. Derby. Subject, The Use of the Artificial Lench in Ophthalmic Surgery. Election of members.

A. T. CABOT, Secretary.

BOOKS AND PAMPHLETS RECEIVED. — Common Mind-Troubles, and the Secret of a Clear Head. By F. Mortimer Granville, M. D., etc. Edited, with additions, by an American Physician. Philadelphia: D. G. Brinton. 1880.

Wood's Library: Veneral Diseases. By E. L. Keyes, A. M., M. D., of New York. Foreign Bodies in Surgery. By Alfred Poulet, M. D., of Val-de-Grace. Handbook of Physical Diagnosis. From the German of Paul Guttman. By Alexander Napier, M. D., of Glasgow.

Lunacy Reform, III. (Reprint from the Archives of Medicine.)

The Population Question at the Medical Society of London. Edited by Charles R. Drysdale, M. D. London. 1879.

A Few Cases of Leprosy. By J. H. Bemis, M. D., Labaina, Maui, H. I. New Orleans. 1880. (Reprint.)

Sea-Air and Sea-Bathing. By John H. Packard, M. D. (American Health Primers.) Philadelphia: Presley Blakiston. 1880.

Post-Mortem Examinations, with especial reference to Medico-Legal Practice. By Rudolph Virchow, of the Berlin Charité Hospital. Translated by T. P. Smith. Philadelphia: Presley Blakiston. 1880.

Dartmouth Medical College. 1880.

Thirteenth Report of the St. John's Hospital, Lowell. 1880.

Muscle Beating, or Active and Passive Home Gymnastics, for Healthy and Unhealthy People. With Illustrations. By C. Klenm, Manager of the Gymnastic Institution in Riga. New York: M. L. Holbrook & Co.

Aspiration of the Knee-Joint. By Henry O. Marey, A. M., M. D. Riverside Press, Cambridge, Mass.

First Annual Report of the Board of Health of the Taxing District of Shelby County (City of Memphis), for the Year 1879. By G. B. Thornton, M. D., President.

Lectures.

DISPLACEMENT OF THE OVARIES.¹

A LECTURE DELIVERED AT RUSH MEDICAL COLLEGE,
CHICAGO, JANUARY 30, 1880.

BY PROFESSOR W. H. BYFORD, M. D.

GENTLEMEN,—Before speaking to you of the displacements and diseases to which the ovaries are subject, I will remind you of some of the more important points in connection with their position and anatomy.

As you probably know, the ovaries are situated on each side of the uterus, to which they are attached by stout fibrous ligaments about one and a half inches long. They occupy the posterior border of the broad ligament, just behind and a little below the Fallopian tubes. When in their natural position they are slightly below the linea ilio-pectinea, and somewhat anterior to the sacro-iliac synchondrosis. When their size and weight are somewhat increased by congestion they may vary from their usual locality by sinking somewhat in the pelvis. The peritoneal membrane of the broad ligament rises around them and embraces the lower two thirds of their substance, but the upper border of these organs stands out free into the peritoneal cavity, in contact with some of the fimbriae of the Fallopian tubes. The main substance or stroma of these organs is made up of a pretty firm, spongy substance, held together by delicate connective tissue. In the cells of this spongy stroma are numerous dark microscopic points, which by some are supposed to be the points around which the ovi-sacs are formed.

In each ovary of the adult woman may be seen several ovi-sacs of different sizes, from the dimensions of a pin's head to that of a pea. Enveloping the whole of this is a strong fibrous membrane called the tunica albuginea. The stroma presents a delicate buff color when incised.

The first deviation from these conditions to which I shall call your attention is their various displacements. Their intimate and firm ligamentous connection with the fundus of the uterus causes them to partake of the changes of position of that part of this organ. When the fundus rises into the abdominal cavity during pregnancy the ovaries are carried up with it, and in very thin persons may sometimes be felt as small movable, sensitive tumors on the sides of the uterus. The same thing occurs in some cases where the uterus is much enlarged by a fibroid tumor. In the former condition the displacement is physiological, and does not ordinarily give rise to serious inconvenience unless the organ is rendered unusually sensitive by disease.

When the uterus is retroverted or retroflexed the ovaries are displaced to a greater or less extent downward and backward. Sometimes the displacement is so great that they may be felt by the side of the fundus uteri in the posterior cul-de-sac, and constitute a very annoying complication. In fact, this condition is often of more consequence than the uterine displacement, and is a serious barrier to the correction of the uterine displacement on account of their liability to be compressed by the instrument used for that purpose. But sometimes the ovaries fall into this position without the uterine deviation. When this is the case there are apt to be many grave symptoms, which are attrib-

uted to that vague and as yet imperfectly understood term "ovarian irritation." In most cases of this sort of displacement the ovaries are the subject of some form of organic change, when we may reasonably doubt whether the symptoms arise from the preëxisting disease more than the deviation of position. There can be no doubt, however, that the displacement very greatly embarrasses their circulation and contributes still further to their morbid condition. In such cases the enormous reflex nervous influences exerted through the genito-spinal centre awaken a long chain of morbid phenomena, destructive of the comfort of the patient, and sometimes establish a series of oöphoro-neuroses, that wreck the patient mentally and bodily.

To complete the variety of ovarian displacement, I must tell you that, rarely, these organs make their way out of the inguinal canal in something of the same way that the testes do in the male. As there is no scrotum, however, in which they can find lodgment, they are arrested at the upper edge of the os pubis, and there constitute a harassing and painful hernia. In passing, I may say that an ovarian hernia may generally be diagnosed from an omental or intestinal hernia, from the facts, in the first place, that these last two seldom pass out of the inguinal ring in females, but frequently through the femoral ring; secondly, that they are not particularly sensitive to the touch unless in a state of inflammation from strangulation, while the ovary is *always* sensitive; and, thirdly, the sensitiveness of the ovary is said to be peculiar, resembling nothing so much as the sickening sensation experienced upon pressing the testicle.

After saying this much with reference to the different varieties of ovarian displacement, I desire to confine my remarks to the pelvic deviation of position. What are the symptoms of pelvic displacement of the ovaries? I have already alluded to these, and shall be very brief in my further development of them. They may be included under two heads, namely, local and general. The local symptoms are not distinctive: pain, weight, or bearing-down sensations and sometimes heat in the pelvis, backache, sacral or coccygeal tenderness, and occasionally radiating neuralgia. There is also very frequently, though not always, some sort of menstrual derangement. But these local symptoms may be produced by many of the disorders incident to other organs of the pelvis.

Now as to the general symptoms, they are very numerous and varied. It is indeed questionable whether all the hystero-neuroses ought not to be regarded as oöphoro-neuroses, direct or indirect morbid emanations from the ovaries themselves.

It is probably impossible for us completely to separate the general symptoms arising from disease of the pelvic viscera into uterine, ovarian, vaginal, and vulvar. The nervous supply to these organs is essentially a unit, and for their nervous influence they are subject to the same presiding centres. In them is comprised a circle of functions to the perfection of which soundness of all the organs is essential.

Whether the terrible nervous symptoms arising from certain diseases of the vulva, the vagina, or the uterus can be reflected upon the organization in any other way than through their connection with the ovaries is, I say, a question not yet solved. I think we cannot doubt, however, that to the term "ovarian irritation" may be attributed the whole array of reflex nervous phenomena so frequently noticed in the wrecked con-

¹ Reported for the JOURNAL by B. W. Griffin, M. D.

stitutions of broken-down women. In the retro-uterine displacements of the ovaries these conditions are prominent features. The nervous symptoms often assume a very aggravated form, and the suffering of the patient becomes unendurable. The general symptoms are those of ovarian irritation; and this is to be expected, because the circulation and innervation of these organs must necessarily be much affected by the malposition. The diagnosis of the displacements of the ovaries is not generally very difficult. When they are in the inguinal canal, on examination of the tumor its shape and peculiar sensitiveness are both peculiar. The only thing for which this displacement may be mistaken is hernia of the omentum or intestine. A tumor formed by the protrusion of either of these is more globular, less firm, and, unless in a state of strangulation, not very sensitive. The sensitiveness of the ovary has been compared to the peculiar sensitiveness of the testicle; while the sensitiveness of the omental or intestinal hernia is the tenderness of inflammation. When in the cul-de-sac behind the uterus, the ovary, if not changed in shape by disease, has the same outline as when naturally situated, and is movable. We may reach it by passing one or two fingers deep into the vagina or rectum.

In many instances their displacement is associated with retroversion or retroflexion of the uterus, apparently the result of the malposition of that organ. In others, however, the ovaries fall into the pouch behind the uterus, because of their enlargement and increased weight from structural disease. Possibly a relaxed condition of the fold of the broad ligament in which it is contained may permit the ovary to settle down out of its natural position.

Is displacement of the ovaries always and necessarily accompanied by serious local symptoms or distressing general disturbances? I think not. Probably every gynecologist of extensive observation has noticed instances in which the ovaries could be felt in the cul-de-sac, and the patient experienced little, if any, inconvenience from such malposition. These, judging from my own observation, are not very uncommon cases.

Why should some patients suffer so much from these displacements, while others meet with so little inconvenience from them? I must employ another term that is not very definite, and perhaps not always intelligible, to answer this question, — "nervous susceptibility." This nervous susceptibility seems with some patients to be the result of their original constitution, or "make up," if you please, while with others it is an acquired condition. Nervous susceptibility and neurasthenia, if not connected as cause and effect, are very closely associated. To treat these cases successfully we must have in mind this important item of "nervous susceptibility" or neurasthenia in this connection.

When displacement gives rise to symptoms of ovarian irritation, what is the prospect of relief? Such cases are justly regarded as very unpromising, but not necessarily incurable. The treatment of the symptoms attendant, and to some extent dependent, upon displacement of the ovaries is sometimes followed by the most satisfactory results. By treating the symptoms I do not mean the administration of medicines for the relief of nervous headache, hysterical convulsions, sleeplessness, etc., but the removal of the condition of the system which encourages their manifestation.

Whatever may have been the diathesis of our immediate ancestors, whether they were afflicted with dis-

eases resulting largely from hyperæmia or plethora or not, it is evident that we have fallen upon times when anæmia or hydræmia among women is, to say the least, a very common state of the general system. This is especially the case with a large proportion of patients suffering from ovarian irritation, either with or without displacement of the ovaries, and the nervous centres in such people are habitually anæmic. Nervous exhaustion means imperfect nutrition or lack of trophic energy in the nervous centres. This, I have no doubt, is mainly because there is not a sufficient amount of good rich blood circulating through them. I cannot understand how nervous exhaustion can take place when there is an unailing supply of nutrition to the centres; but it is plain that an exhaustion of supply will render the regular working of the brain and spinal cord as nervous centres impossible. It is blood exhaustion instead of nervous exhaustion.

I have allowed myself this much physiological speculation as an introduction to what I have to say about general treatment.

What we want to do with these patients is to turn them entirely around in their habits, and lead them to the adoption of measures that will make them plenty of blood and fat.

Dr. Weir Mitchell has taught us how to do this and his system of managing patients of this character is admirable. It is not always practicable, nor indeed necessary, to adopt his method as a whole. This, however, does not detract from its merits. Absolute rest is essential only in cases of extreme prostration.

In most instances active exercise will be better than passive, and should always be enjoined upon the patient and attendants. The exercise in kind and quality should be prescribed and enforced with exacting regularity, or induced by diversion that will not fail.

The most important part of the treatment, however, is the regulation of food. By regulation of the food I mean the prescription of it in items and quantity from day to day. My routine prescription is four ounces of beef-steak for breakfast, with bread and butter or toast, potatoes and other vegetables, as the capacity for digestion will allow; six ounces of roast beef or mutton, bread and butter, potatoes and vegetables for dinner; for supper the same as for breakfast. After each meal and at bed-time one pint of good fresh milk. With this or some other equivalent method of feeding the patient, there should be associated some plan by which the patient can get plenty of fresh air and have as much exercise as she is able to take. The exercise may be passive at first, but as soon as possible it ought to be active. Active exercise may be begun by having the patient walk supported as much as necessary by a strong nurse. After she can walk alone the support ought to be withheld. You will see, gentlemen, that I do not advise rest, but exercise. I advise exercise because I have proved by experiment, I think, that it is much to be preferred. If nutrition can be supplied the patient will profit by exercise; if nutrition is impossible, then of course exercise will be impossible. Before leaving this part of the subject allow me to say that the limit I would place to the amount of food of the kind I have indicated is the capacity of the stomach to digest it. If the food is not rejected by vomiting, or it does not irritate the bowels enough to cause diarrhoea, I would not allow the want of appetite or the inconveniences that may arise during digestion to be considered as reasons for not taking it. Usually the

stomach will soon become tolerant and after a time the enriched blood circulating through its glandular apparatus will engender a relish for food, and the patient will eat with pleasure. This intimation that an anæmic stomach digests with difficulty is intentional; for I do not believe that energetic innervation, if that were possible without adequate supply of blood, is sufficient to secure good digestion.

I have said nothing about the use of medicines to aid digestion or to increase nerve force, not because I have no faith in them, but for the reason that I believe them of secondary importance, — mere adjuvants instead of principals in the treatment of this condition of the system. I could cite a number of instances in which this course of treatment resulted in averting the dangers and mutilations of the more heroic method of castration by establishing a vigorous and tolerant condition of the nervous system, and thus cured "ovarian irritation." These remarks are applicable to other cases beside displacement of the ovaries in which there is ovarian irritation.

As to the management of the few instances where the ovaries are borne down by a displaced uterus, we may occasionally correct the displacement so far as greatly to improve the circulation of these organs, and thus remove the great element in ovarian distress. This is of course done by correcting the position of the uterus by proper means of support, — a well-adjusted pessary. In the many cases, however, in which the symptoms are the most grave — retroflexion and retroversion of the uterus — the location of the ovaries in the cul-de-sac beside the fundus is a cause of almost insurmountable difficulty. The instrument is pretty certain to cause pressure upon these sensitive organs, and thus become intolerable. We ought not to despair of accomplishing the object, however, until we have exhausted our ingenuity in mechanical appliances for this purpose. When every other measure fails, either to render the condition of the patient bearable, or to save her from mental or physical wreck, we still have the resource furnished us by Dr. Battey, of Rome, Georgia, namely, the removal of these organs. In taking the consequences of this operation, however, we should remember that it is very dangerous, and that if successful it unsexes our patient in the sense that she is at least barren for all future time.

When the ovaries are displaced so as to occupy the inguinal canal the operation for removing them is less hazardous than when in the pelvic cavity, and for that reason may be resorted to with less hesitation.

THE CAUSE OF SLEEP.¹

BY WILLARD EVERETT SMITH.

It is strange that so practical a thing as sleep should be so illogically investigated. Every one must recognize that there are certain physical conditions accompanying our periodical losses of sensibility which we call sleep, but every one has not recognized that these conditions are almost universally mistaken for actual causes. The gun lock, hammer, percussion-cap, and powder are all of them conditions, but no one would maintain that they are the immediate and efficient

cause of the firing of a gun. They are only disposing causes. The sufficient and exciting cause is that some one has pulled the trigger.

Because this confusion of ideas has been allowed to befog the minds of physiologists, and because the anæmic theory is so firmly rooted in the fancy, many of the attempts to ascertain the active and immediate cause of sleep have been in vain. I say nothing of the mere hypotheses that have been advanced; to accept such vague generalizations as a scientific proof for the complex phenomena of sleep were as sensible as to accept the notion Thomas Cogan held in 1612, that sleep was caused by the ascent of vapors, fumes, etc., from the stomach to the head, and was therefore especially induced by milk, wine, and other drinks.

We must constantly bear in mind always to submit our conclusions to two rigid tests: (1.) Do they incontrovertibly agree with facts? (2.) Do they afford any real explanation of the *cause* of sleep?

The theories offered to explain the immediate cause of sleep are four in number: hyperæmic, anæmic, lactate, and Pilgrer's.

We must not suppose that the hyperæmic and anæmic theories give us a logical dichotomy; that if one be true the other must be false. The hyperæmists concede to the anæmists that the arteries of the brain during sleep may be bloodless, but maintain that this is not the true cause of sleep. According to them, anæmia is only a disposing condition. I hope to show that the most careful observations support neither theory, and that even if they did neither would *prove* anything in regard to the *cause* of sleep.

In discussing the hyperæmic² theory we must remember that there are two kinds of congestion, active and passive; the former due to an excessive nervous excitation, the latter to a want of vascular tonicity. In normal sleep we find a loss of temperature and nerve activity; therefore it is said that we have a passive or venous congestion of the brain. It has been observed, — and both hyperæmists and anæmists accept the very same observations as a foundation for their respective theories, — that the brain when artificially exposed to view becomes during sleep inactive and shrunken because of the anæmic contraction of the capillaries. During waking hours it is said to rise again, and even to protrude above the fractured skull. In the normal skull, then, there would be during sleep a vacuum to be filled. Darham, upon the side of anæmia, says it is filled with cerebro-spinal fluid; Crippie, speaking for hyperæmia, says with venous blood. He thinks the diminution in the molecular vibrations of the brain allows the venous sinuses to enlarge and press so violently upon the gray cortex as to render it inactive.

The hyperæmic theory makes no distinction, except of degree, between sleep and coma, a fatal mistake. That an abnormal insensibility may be produced as well by hyperæmia as by any other pressure upon the brain few would care to deny, but that a normal sleep can be thus produced seems very improbable, both *a priori* and more especially as an authenticated fact.

Even if venous congestion be the actual cause of sleep, what power is there in the system to prevent a still further congestion? Would it not be true that the greater the congestion the less the power to relieve it? Why, then, does not every sleep develop into coma, and why after normal sleep, as after coma, is there not the feeling of languor which always fol-

¹ Read at a Physiological Conference, Harvard Medical School, February 25, 1890.

² Crippie, Causation of Sleep.

lows cerebral congestion? Since such practical questions as these can be asked without hope of satisfactory reply, would it be fair to accept a theory which allows them to be thus propounded?

The anæmic theory¹ steers clear of the intricate hypothesis that venous blood congests in the brain sinuses, and this, *a priori*, seems very probable. What is more reasonable than to say that a free and abundant supply of blood to an organ carries with it activity, while a scanty supply causes a period of inaction? If narcotics and anæsthetics produce sleep, do they not seem to do so through the vaso-constrictor nerves acting upon the cerebral vessels?

This theory holds that during sleep blood is withdrawn from the brain to the alimentary organs. Undoubtedly after a full meal blood is attracted to the stomach to aid digestion, and no one denies that sleep may at such times be agreeable. To say that one is therefore the cause of the other may be and probably is not only to fall into the fallacy of "*post hoc ergo propter hoc*," but also to misinterpret facts. When sleeping after a heavy meal we are likely to present a face, to say the best, not much paled from loss of cerebral blood, but on the contrary often considerably flushed.

On the whole, however, anæmia seems so very plausible that we might perhaps hope there were no objections to it. Let us see. It is well known that cold will produce insensibility with the appearance of anæmia, heat with hyperæmia. Hammond found that chloroform caused sleep by an increased, but ether and opium by a decreased, cerebral vascularity; Vulpius, that ether did not produce much pallor of the brain, that chloroform had still less effect upon vascularity, and opium no effect at all. The action of narcotics, judged by the most careful experiments, is neither to increase nor to decrease vascularity, but to diminish the power of the blood to absorb oxygen and nourish the tissues. It thus favors the theory of sleep advocated by Pfliiger.

Vulpius has destroyed what little plausibility either hyperæmia or anæmia ever had. From his experiments, as well as from the confessions of the advocates of the theories, we are justified in maintaining that although during sleep there may be a slight hyperæmia followed by a slight anæmia, neither appear to precede but only to accompany sleep. Both are effects rather than causes. We can now understand, perhaps, why we feel sleepy when we have eaten a hearty meal, when our feet are at the fire, or when we are exposed to a cold temperature. Some of the conditions attending sleep having been freely furnished us, we are forced, *nolens volens* (generally *nolens*), to yield to them.

This, however, is far from accounting for the fact that sleep regularly and periodically returns to us to repair our wasted energies. Indeed, it does not give the least hope of a solution of that problem. What we demand to know is, granting for the sake of argument that the brain is anæmic during sleep, why it should be so. To reply that it is weary, inactive, anæmic, and therefore is produced sleep, is simply to restate what may be an erroneous idea without assigning the least reason for holding to such an idea. In truth, it seems rather ludicrous, in view of the fact that the inactive state of the brain has been considered to mean sleep, to say that the brain is inactive, therefore anæmic, and

therefore causing sleep, the state with which we started. We reason in a circle, assuming what we wish to prove, and trying to prove what we have already assumed. Thus far, then, we have investigated only some of the conditions attending sleep, but have got no inkling of a cause.

The only theories that even attempt to assign a logical reason for periodical inactivity are the lactate theory and the theory offered by Pfliiger.

I have said that Durham favored the anæmic theory. He does to a certain extent. Nothing, however, has surprised me more than to find him everywhere quoted, even by Vulpius, as the ardent disciple of the theory. I fail to understand how any man can read the essay so as to comprehend it, and then say that Durham believes anæmia to be the cause of sleep. He believes it to be only a condition, and to the question, "What are the proximate causes of such conditions?" very distinctly replies that the probable reason why sleep follows activity is because "the products of chemical action interfere with the continuance of the action by which they are produced." As one of these products he specifies lactic acid.

This can be nothing more nor less than the lactate theory, as recently held by Preyer² and Obersteiner; an exceedingly ingenious theory, resting, however, not upon facts, but merely upon supposition and analogy. We know that the accumulation of lactic and butyric acids hinders the fermentation by which they are produced, that muscle supercharged with lactic acid loses its contractility, that a candle expires in a closed box from the CO₂ generated, and that an electrical battery stops from the accumulation of ZnSO₄. May it not be, then (although we have no direct proof), that in the brain the products of decomposition accumulate faster than they can be excreted?

The most conclusive proof we can obtain is by giving subcutaneous injections of lactates and watching the results. Even the experiments of Preyer, the especial advocate of the theory, were by no means uniformly successful, while those of Drs. Erlcr, Mendel, and Auerbach were almost complete failures. Dr. Auerbach experimented upon sixty patients in a lunatic asylum, some of them being accustomed to sedatives, others not. The dose, varying from ten to thirty-five grains of lactic acid, from twenty to forty grains of lactate of soda, was given during both day and night, under the most favorable collateral conditions. In not a single case was there a sedative effect, but on the contrary in one third of the cases severe intestinal disturbance.

The theory has a plausibility drawn from the fact that the amount of the CO₂ exhaled and of the lactic acid produced in a muscle during contraction is so nearly the same as to suggest a common origin. It loses its probability from these practical experiments, which go to show that, although muscular irritability may be impaired by the accumulation of the products of decomposition, the vitality of the brain is not thus impaired.

The theory advocated by Pfliiger strives to show that it is not the accumulation of waste products that checks the nervous system, but the lack of certain vital conditions. The theory is not entirely original with him. It was foreshadowed by Carnichael, Binz, Ranke, Henker, Sommer, and Richardson. These all queried whether the substance of the brain might not

¹ Hammond, Sleep and its Derangements. Durham, Guy's Hospital Reports, 1860, third series, vol. vi.

² Centralblatt, 1875.

be so modified that external stimuli would be powerless to create cerebral molecular motion. Had the question been asked of them, "Why and how does the brain become so changed?" no answer could have been given. There was simply a tendency of thought in the right direction. Brown-Séquard called sleep a sub-*asphyxia*. Vulpian got so far as to say that the influence of various narcotics was to be found, not in the "vascular modification of the nervous centres," but in some direct "histo-chemical alteration" of the centres themselves.

Pflüger¹ has made the experiments of Voit, Bernard, and Vulpian upon respiration of great account in his theory. He has noticed that frogs deprived of oxygen for a long time become as it were "sleep-drunk," and then insensible. Is this due to a lack of oxygen, to an excess of CO_2 , or to both? When an animal breathes an atmosphere containing only nitrogen, dyspnea follows, but the CO_2 which is generated diffuses, and does not accumulate in the blood. On the other hand, if the animal breathes an atmosphere rich in CO_2 , but at the same time rich in oxygen, true dyspnea does not occur. The action of insufficiently arterialized blood upon the respiratory centres is due, then, to a deficiency of oxygen.

The next question that arises is, "Does this deficiency primarily occur in the blood or in the tissues?" Several different experiments prove that the oxidation of our body takes place primarily in our tissues, and that then the products of decomposition pass into the blood. For example, a frog in which the blood was replaced by a normal saline solution continued for a time all the respirations and oxidations as before the operation; and Pflüger has shown that a frog at a low temperature will continue to produce CO_2 in an atmosphere totally deprived of oxygen. The oxygen necessary to form this CO_2 must have been stored up in the tissues previous to the experiment. Muscle, however, contains no free oxygen, and is not directly oxidized. The oxygen necessary for its oxidation must then, before it can be converted into CO_2 , pass from the hemoglobin of the blood into the tissues, where, in some unknown way, it is locked up as in a store-house.

When, in a way equally unknown, this intramolecular oxygen is unlocked and chemically united with the tissues to form the CO_2 , it produces a little explosion, which excites molecular vibrations that are at once distributed throughout the nervous system. All investigations favor the belief that in the gray cortex of the brain exist the most ready conditions for the breaking up of living matter, since no part of the body needs oxygen for its life as much as the brain. So quickly is the brain destroyed by lack of oxygen that it cannot be restored even when restoration of the spinal cord is still possible.

The consumption of this molecular elasticity of the brain is, however, so great that during our hours of action the absorption of oxygen into the tissues cannot keep pace with the molecular disintegration. Gradually the explosions become less frequent and powerful; stimuli have less and less effect; the cohesion of the cerebral molecules becomes greater and greater, until finally an impulse upon them is without effect. They are insensible to stimuli, and we say we are asleep. The fundamental idea, then, in the theory is that a certain amount of intramolecular oxygen is necessary for the waking state.

It is well known that during sleep the respiration is slower and deeper, the exhalations are less, the beats of the heart slower and less forcible, the circulation is less rapid, and the body heat somewhat lower than during waking hours. It is well known, too, that the voluntary muscles and nerves are at rest, and that some organs—for example, the stomach—are comparatively inactive. These are, however, effects, not causes. At such times the body is unfavorable to oxidation. Oxygen can therefore be stored up. After a time the molecules of the brain are so saturated with this oxygen that their oscillations become more frequent and powerful. They furnish a stimulus to awaken the bodily activity.

Is it not an objection to the theory, however, that we need to sleep so large a part, say one third, of our time to store up this oxygen in the tissues? I do not think so. It is not maintained that there is absolutely no activity in the body during sleep, but that the accumulation of this oxygen results simply as an overplus which is not expended, and which can therefore be absorbed or stored up. Neither is it claimed that all the force, that is, all the intramolecular oxygen of the brain, is consumed by fatigue, because we know that the will—an internal stimulus—has great power to urge on our flagging energies, even when external stimuli fail us. Fatigue from over-exhaustion comes partly from exhaustion of muscular fibres, partly from exhaustion of motor nerves, but chiefly from exhaustion of that portion of the central nervous system which produces voluntary impulses. The will rarely, if ever, calls forth the full powers of the tissues. If, however, every external stimulus could be removed we might expect, even *a priori*, that sleep would ensue, because we know that absence of stimuli must decrease cerebral molecular motion, and consequently the consumption of oxygen.

It has been the good fortune of science to confirm such an expectation by an actual experiment.² A young man of sixteen appeared, in the spring of 1876, at the hospital in Leipsic. His entire skin and muscles had so lost sensation and power that he could be burned or made to move around the room without any feeling of pain or motion. He had lost taste, smell, sight in the left eye, and hearing in the right ear. His only means of receiving sensations was by his right eye and left ear. If these were artificially closed by an attendant, the boy, after two or three minutes of restlessness, would go into a sound and tranquil sleep. This experiment could be repeated whenever desired. By throwing a flash of light upon his eye, or by making a loud sound close to his ear, he could be awakened; if left alone, he would after a few hours awaken of himself, from either external or internal stimulus.

This is in striking confirmation of the theory. To be sure, the boy might not exhaust all his intramolecular oxygen between the times he might be put to sleep; but it must be remembered that he did not at such times go to sleep of his own sweet will and by a demand of nature,—he was put to sleep by diminishing molecular disintegration.

While every evidence, then, is in favor of this theory, we cannot say that it has been perfectly elaborated. It has yet to explain how the store of intramolecular oxygen is exhausted in the nervous system, and exactly what are the resulting molecular changes in

¹ Archiv x.

² Recorded by Strömpell in Archiv. xv.

the brain. Although it has not answered the question *how*, it has answered the question *why*, some "histochemical" change takes place in the nerve centres. It offers a sufficient reason for the periodicity of sleep and for the influence stimuli, both external and internal, exert upon sleep. The possibility of mistaking effect for cause in it is reduced to a minimum. In a word, it is the only theory ever advanced upon the subject which even attempts consistently both with theory and facts to assign an active, immediate *cause* for sleep.

RECENT PROGRESS IN PHYSIOLOGY.

BY G. M. GARLAND, M. D.

DIGESTIVE FLUIDS.

THE researches of Richet¹ have thrown some additional light upon the vexed question of the cause of activity in the gastric juice. The method employed depended upon the observation of Berthelot that when an acid solution is shaken up with an equal volume of ether the free acid, if organic, is distributed between the two fluids, but if mineral, remains almost entirely in the water. The number which expresses the proportion in which the acid is divided between the two fluids is called by Berthelot the "coefficient of distribution," and is constant for each acid. Pure gastric juice, when tested in this way, was found to have a coefficient of distribution very different from that of hydrochloric acid; but by combining hydrochloric acid with various organic substances found in the stomach itself, Richet succeeded in producing a compound which resembled the gastric juice not only in its coefficient of distribution, but in its action upon cane sugar, starch, etc. Richet therefore considers that in pure gastric juice the hydrochloric acid is united with organic substances, particularly with leucine, which somewhat modify its action as a mineral acid. The products of digestion obtained from albuminoid materials by the use of this combination of acid and leucine seem to be much more diffusible than those obtained by pure hydrochloric acid. During the progress of digestion the hydrochloric acid of the pure gastric juice is to a certain extent replaced by phosphoric and lactic acids derived from the food, and separated from their combinations there by the stronger mineral acid with which they are brought in contact. There is also, in certain cases, an acid fermentation in the contents of the stomach, resulting in the production of an additional amount of acid. The *mixed gastric juice* as found in the stomach after several hours' digestion is therefore a very different fluid from the *pure gastric juice* as originally secreted.

These experiments of Richet have been repeated and confirmed by a recent French writer.

This observer has also investigated the action of the pancreatic juice upon the various classes of nutriment in the presence of the gastric juice. The pancreatic juice is found to be a very delicate reagent for determining whether the gastric juice thus used is "pure" or "mixed;" that is, whether its acidity is due to hydrochloric acid alone, or to other acids (phosphoric, tartaric, lactic, etc.) set free from the food by the stronger mineral acid or produced by fermentation. In the former case pancreatine is found to be without

action upon starch, and to digest only five times its weight of albumen; whereas, in the latter case it converts seven times its weight of starch into sugar and changes thirty-eight times its weight of albumen into peptones.

DIASTOLE OF THE HEART.

The diastole of the heart is generally assumed to be a period of rest during which the wear and tear of the previous contraction is remedied, and those who strive after proofs of infinite wisdom in the constructive agencies of the body have delighted themselves in figuring out the amount of rest allowed a weary, self-destroying heart during the busy period of life. On the other hand, skeptics have frequently arisen to deny that the heart is indulged with rest during diastole; for they claim that this phase of its existence is as much an active one as is the systole, the two differing only in intensity. Among such skeptics were Galen and Vesalius. Haller was an advocate of the rest theory, for he considered the heart purely passive during dilatation.

This question has excited much interest of late, especially among Italian and German physiologists, and the discussion thereon has been illustrated by many interesting experiments. Fick introduced a canula into the left ventricle of a dog and connected it with his spring manometer and thereby discovered that the blood pressure inside that cavity was apparently less than in the aorta. Gräde observed the same peculiar condition with a mercury manometer. It seemed hardly credible, however, that the tension in the aorta could exceed that in the ventricle, since the former is directly derived from the latter. It was contended, therefore, that the apparent difference was due to the fact that the spring and the mercury manometers were too sluggish in their movements to trace accurately the rapid variations of pressure which constantly occur in the ventricle. Hence Marey² tested the point with his more delicate air drums, and found that the maximum pressure in the ventricle exceeds that in the aorta.³ Goltz and Gaule examined the subject by a very ingenious method. Every one knows that an ordinary Davidson syringe bulb exercises a suction force through one of its tubes and a positive pressure through the other by means of the opposite action of its corresponding valves. It is also clear that a manometer attached to the nozzle tube of the syringe would exhibit the amount of force with which the bulb contracts, while another manometer, attached to the opposite or basin tube, would show only the negative force exerted by the reëxpansion of the bulb. Goltz took advantage of this simple arrangement of valves in the following manner: he passed a canula through the right carotid of a dog into the aorta, and thence into the left ventricle. The outer end of the canula was connected with a manometer by means of a tube which contained a valve. This valve could be reversed at will, and thus the manometer could be made to record alternately the direct or maximum pressure produced by the contraction, or by a series of contractions, of the ventricle, and the negative or minimum pressure developed during the reëxpansion of the same. Testing first the positive force, he found that the maximum pressure in the ventricle is always a little *greater* than in the aorta. Comparing the two ventricles he obtained the following figures:—

² Marey, *Physiologie mët. de la Circulation du Sang*.

³ Arch. f. d. ges. Physiologie, 1878; Bd. xvii. p. 200.

¹ Journal de l'Anatomie et de la Physiologie, March and April, 1878.

Maximum systolic pressure in left ventricle = 135 mm. mercury.
Maximum systolic pressure in right ventricle = 61.8 mm. mercury.

On reversing the action of the valve he discovered that the left ventricle in expanding exerts a minimum or negative pressure of 52 — mm., mercury, while the right ventricle records — 17.2 mm. As an average he finds that a dog's heart can suck with a force equal to — 320 mm. of water, and the intensity of this force depends on that of the contraction. On taking the heart out of the body and squeezing it, and then noting the force with which it expanded, he could obtain a suction of only — 100 to — 200 mm. of water. In other words, the physiological expansion of the heart is accomplished with more force than that which follows an artificial compression of heart. Mosso poured water around a frog's heart in a small chamber, until the weight of the water prevented further movements, that is, kept the heart compressed. He thus found that 15 to 20 mm. of water are necessary to overcome the diastolic resiliency of the frog's heart.

Morison¹ cut out a sheep's heart, and tied all its outlets except the pulmonary artery, which was connected by a canula and tube, with a manometer. Then squeezing the left ventricle he found it would, on re-expanding, draw up a column of water 30 mm. high. The right ventricle did the same thing to less extent. On injecting the coronary arteries and repeating the experiment, he found that the left ventricle would suck up 120 mm. of water, or four times as much as before.

The influence thus exerted by the coronary arteries has been noticed by Brücke, Donders, and others, who have argued that the diastolic expansion of the heart is intensified by the rush of blood into those arteries from the aorta. Brücke says the semilunar valves are thrown widely open by the discharge of blood out of the ventricle during systole, and are thus brought to lie against the orifices of the coronary arteries in such a way as to prevent blood from entering therein during that phase of the cardiac action. Moreover, he thinks that the blood is even squeezed out of the arteries by the contraction of the muscles. Then, as systole ceases, the cardiac muscles relax; the valves close and uncover the coronary orifices; the distended aorta rebounds and drives blood into the coronary arteries, thereby producing a diastolic erection of the cardiac walls. Donders injected these arteries forcibly, and found that by so doing he was able to produce a diminished pressure in the cavities of the heart, as indicated by manometers attached to the same.

Ceradini² contests this theory on the following grounds: he says that the semilunar valves do not cover the mouths of the coronary arteries, and therefore can not hinder the entrance of blood during systole. Moreover, he has observed, by introducing canulas into these arteries, that the blood spurts out of them during systole, and not during diastole. Brücke says that this spurt of blood is that which enters the arteries at the very beginning of systole, while the valves are opening, but have not yet come against the orifices. Ceradini says that this systolic pulse indicates that the orifices are open both in systole and diastole, and that the rapidity of flow through them is greater in systole than in diastole.

Among the Italians, Luciani has shown a strong in-

terest in this subject, and advances the following considerations to prove that the ventricles are active in diastole: —

(1.) During the systole of the auricles one does not observe a reflux of blood into the vena cava, although those veins are not guarded by valves. This shows that the pressure in the auricle does not exceed that in the veins, and this is due to the fact that the ventricle keeps the auricular tension down by aspirating blood toward itself during its own diastole.

(2.) In the horse, whose heart-beats are slow, and in whom the auricular systole does not begin until near the close of ventricular diastole, we can attach a manometer to the vena cava and see a negative wave of aspiration occur at beginning of ventricular diastole.

(3.) Place a canula in the ventricular cavity of a dog and connect it with a horizontal tube, and one can see a slight aspiration of blood with each diastole.

These various experiments seem to prove indubitably that the ventricles of the heart do exert a negative force during their diastole, and thus assist the circulation in a twofold manner. Simple as the problem thus far appears, it becomes more obscure and more difficult when one tries to explain the mechanism of this diastolic aspiration. Some say it is the negative pressure which is exerted on all the organs of the chest, the heart included. This explanation is unsatisfactory, because it can readily be shown that the diastolic aspiration persists in expiration as well as in inspiration, and even when chest is opened and heart removed from body. Others maintain that the aspiration is due to forcible rebound of cardiac walls after the systolic compression. It is not proven, however, that the heart can squeeze itself powerfully enough to cause such a rebound. Luciani thinks that the heart is supplied with two sets of nerves, — contractors and dilators. Under the influence of the former the longitudinal axis of the molecules of the muscle becomes shorter and the heart contracts, while the dilator nerves produce an elongation of the axis of the molecule and a corresponding dilatation of the heart. Thus he claims that irritation of the vagus does not stop the heart by paralyzing it, but by inducing a particular condition of extension of the muscular fibres, — a sort of "extensible tetanus." A very feeble irritation of the vagus will sometimes cause a contraction of the heart, and Luciani explains this by the hypothesis that the vagus also contains contractile fibres, which are more excitable than the dilator fibres, and therefore become active first. As the irritation increases, however, the action of the dilators begins to overpower that of the contractors, and dilatation takes place.

Another argument in favor of this diastolic activity is derived from some experiments of Claude Bernard. He observed that the injection of quinine into the circulation produced at first an enfeeblement of the systole and a prolongation of the diastole, and that finally the heart became quiescent in a state of exaggerated dilatation which exceeded the ordinary cadaveric diastole. Mosso is a strong opponent to the theory that diastole is marked by an active protrusion of the molecules of the cardiac muscles. He found, as stated above, that fifteen to twenty mm. of water would suffice to overcome the tendency to a diastolic expansion in a frog's heart, while the same heart would lift seven hundred and fifty mm. of water during systole. He seems to think that the mechanical rebound of the heart after compression is sufficient to account for so slight a force.

¹ Edin. Med. Journal, November and December, 1879.

² Der Mechanismus der halbmondförmigen Herzklappen, Dr. Julius Ceradini, Leipzig, 1872.

He cut out a frog's heart and bathed it in a five per cent. solution of neutral sulphate of quinia. This brought the heart to rest in diastole, but the expansion was no more than ordinarily occurs, and therefore Mosso does not believe that quinine can produce an exaggerated diastole.

Engelmann advances an ingenious theory to explain the mechanism of muscular action. He supposes that certain portions or segments of a muscular fibrilla become endowed with a higher absorbing power under the stimulus of nervous impulse, and that they thereby draw into themselves a larger amount of water from neighboring segments. By this means the muscle assumes a greater transverse diameter and a shorter longitudinal one, that is, it contracts. When the osmotic current tends in an opposite direction the reverse of this phenomena occurs, and the muscle elongates or expands. If this be true, then both muscular contraction and elongation are determined by osmotic force, and one may be considered as essentially active as the other, though they may differ from each other in intensity.

To sum up, it is evident that the heart exerts an aspiratory force during its diastole, and thus accelerates the approach of blood to itself, but different authors vary widely regarding the mechanism of this phenomena. A full index to the literature of this subject may be found in the *Revue des Sciences médicales*, tome ix, page 345.

ORIGIN OF THE ASPIRATORY FORCE IN THE CHEST.

Bernstein¹ has raised the question as to the moment and manner in which a negative pressure is established within the human chest. Evidently such a pressure cannot exist in utero, or it would draw the amniotic fluid into the lungs. To test this point Bernstein attached a manometer to the trachea of a still-born infant. Then, having inflated the child's lungs, he opened the chest wall, and found that they contracted with a force equal to 6 or 7 mm. of mercury. This shows that the first breath creates a permanent enlargement of the thoracic cavity. This increased space, he thinks, may result from the driving out of blood which cannot afterward return, or from the establishment of a new set to the ribs.

The latter explanation would seem the more plausible, and Bernstein found that the transverse diameter of the chest is permanently increased 1.4 mm. by inflation. He was unable to explain this inability of the ribs to resume their original position, but suggested that it might be due to some cog-and-ratchet arrangement of the costo-vertebral joint; or that the elastic expiratory agents of the chest might be so over-stretched that they assume a new set, and are thus unable to bring the chest back to its former position.

— Dr. W. J. Morton, of New York, has been invited to deliver the course of lectures on Diseases of the Nervous System in the University of Vermont, Burlington, during the present term.

— A correspondent of the *Medical Times and Gazette* says: "So long ago as 1733, Mr. Paul, a surgeon at Stroud, Gloucestershire, extracted from the kidney of a woman, by an incision through her back, a rough stone as large as a pigeon's egg, and made an entire cure."

Hospital Practice and Clinical Memoranda.

TWO CASES OF HYSTERO-NEUROSES.

BY G. H. LYMAN, M. D.

Few physicians will find it difficult to recall puzzling and annoying cases of long-continued and painful affections, which, for want of a more definite name, they have ranked under the convenient head of neuralgia, or which, perhaps, the simulation being perfect, have with a more positive diagnosis treated a long time without success for cerebral, cardiac, pulmonary, or gastric disorder, until finally, their true reflex character being discovered by themselves, or possibly, to their annoyance, by others, relief is prompt and effectual. I could recount many such cases which have fallen under my own observation: a chronic dyspepsia, for instance, of many years' duration, which was immediately and permanently relieved by the simple rectification of a retroverted uterus; anaesthesia and threatened paralysis of one leg, lasting for months, due to a similar cause, as clearly proved by the result; an exhausting laryngeal cough, continuing half the night for weeks, and resisting all general and local medication, until its cause was discovered in an irritable uterus.

The following cases, occurring recently in my service at the City Hospital, are worth reporting as striking examples of unusual forms, treated for a considerable time without relief before their reflex character was suspected. For the distinction to be made between such cases and the ordinary manifestations of hysteria I would refer to the excellent paper by Dr. Engelmann in the second volume of the *American Gynaecological Transactions*, my experience leading me to acquiesce in his statement that ordinary hysteria is "but very indirectly influenced by the condition of the uterus," meaning thereby its pathological and not its physiological condition.

CASE I. E. M. K., aged nineteen, unmarried, entered the hospital on the 12th of June, 1879, with slight febricula, which ran its course with no unusual symptom but a tendency to vomiting. July 3d she was transferred to another ward to be treated for leucorrhœa. She reported that her catamenia began at fifteen, and that she had been always well before entering the hospital. As will be seen later this was incorrect, and probably arose from her reluctance to speak of these details unless closely questioned in reference thereto.

July 11th. Has a slight, dry cough, and for the past two days it is noted that she is able to retain nothing but a little milk.

July 22d. She now says that all last winter she had pain and distress in epigastrium after eating, and that she vomited blood two or three times. No hæmatemesis noted since entrance.

July 26th. Food is now given only by the rectum.

July 29th. Able to retain but a teaspoonful of milk at a time.

August 1st. A digital examination was made, and the uterus was found to be in position. Some tenderness in the left cul-de-sac and iliac region; dysuria. For the next three weeks her condition was not materially changed; sometimes able to retain a little food, but generally not. Complains occasionally of dysuria and pelvic pain. Her symptoms were at-

tributed to gastric ulcer, and for this she was treated until she left the hospital, on the 23d. On the 18th October she was readmitted, the treatment having been continued outside. Her physician reports a continuation of the vomiting, but no blood, and no localized pain in the greater curvature; food never retained over ten or fifteen minutes. Bowels costive; micturition frequent (twenty-seven times in one day), with burning and tenesmus. It is now ascertained that for the last three years her catamenia have been irregular and painful, and on examination, October 29th, with speculum, through a resisting hymen, a well-marked endocervicitis was revealed, with profuse secretion from the os, the circumference being extensively abraded. The cervix was thoroughly scarified, and iodine was freely applied within and without.

November 6th. The erosion but little modified. Treatment repeated. *No vomiting since the first application.* Ordered beefsteak, which was relished and well borne.

November 15th. Has vomited once since last report, and is occasionally distressed by solid food. She has Valentine's extract, tea, toast, and beefsteak. Menstruation causes no increase of symptoms. Bowels torpid. A large furuncle upon nates.

November 28th. Has rejected her food two or three times only since last report. The erosion has healed entirely, leaving a decided congestion and profuse cervical discharge. To modify the nutrition of the parts more thoroughly fuming nitric acid was applied.

December 7th. Granulations from slough exuberant, and touched very lightly with nitrate of silver.

December 23d. Cervix entirely healed and looking healthy. Since last report has had a sharp attack of diphtheritic sore-throat.

December 25th. No pain, no vomiting, and says she feels perfectly well, and is discharged to return to her home in Nova Scotia.

CASE II. A. B., aged twenty-seven, widow. This patient was admitted to the hospital for acute rheumatism November 23, 1879. She reports that for three months she has suffered from rheumatic pains in both legs, commencing in the ankles and extending to the knees, and of late to some degree to the thighs. For the past fortnight these pains have been worse, with the knees and ankles excessively tender to the touch, and she thinks there has been some swelling. Pain more severe at night. No specific history. Bowels torpid. Micturition frequent and burning. Catamenia irregular, intervals varying from one week to four weeks, very painful, and occasionally excessive. At the first visit the limbs were found enveloped in cotton. Temperature 101.2° F.; pulse 100; tongue coated. The slightest attempt at examination of the limbs caused such turbulent outcries that it was desisted from, and as the diagnosis of acute rheumatism seemed rational enough she was ordered salicylic acid, and for temporary relief subcutaneous injections of morphine. A week later (November 30th), as there was no apparent improvement under treatment, the cotton envelopes were carefully removed, against her vehement protest and apparent suffering. On exposure to the air intense clonic contractions of flexor tendons at ankles and knees occurred, and excessive rigidity of the muscles, causing great pain. The true nature of the case was now suspected.

December 10th. At the termination of a catamenial period examination showed the uterus to be very

tender. There was intense endocervicitis, with abundant discharge of muco-pus from the cervix. No uterine displacement. Vaginal walls somewhat injected. The uterus was swabbed with a strong solution of carbolic acid, and hot carbolized vaginal douches were ordered.

December 11th. The intense pains of the limbs, of some three months' duration, and simulating so completely acute rheumatism, *have disappeared*, and the patient flexes the thighs sharply upon the abdomen without assistance and without complaint.

December 12th. Cervical discharge continues. Vaginal injection repeated.

December 14th. Improved. Secretion from cervix diminished and less purulent. The cervical membrane freely scarified, and acid reapplied. Has had no recurrence of the muscular pains. Sleeps well without an anodyne.

December 31st. Has menstruated during the past week without complaint. The vaginitis has disappeared. There still being a slight discharge from the cervix, the os was again scarified and the acid applied for the last time. She remained another month in the hospital for rest and tonic treatment, and was discharged, well.

CASE OF CONGENITAL UNILATERAL COLOR-BLINDNESS.¹

BY OTTO BECKER.

THE occurrence of congenital color-blindness confined to one eye has not heretofore been indubitably established.

In 1868 Niemetschek² described a case of unilateral color-blindness, which by many authors is viewed as congenital. But Niemetschek expressly says that the visual disturbances of his patient, a man of forty-six, had appeared but a few years before his examination. Vision, both near and distant, was poor in both eyes. Exact data as to refraction and visual power were not given. The patient himself observed that the shadows in a folded white handkerchief appeared to him green. He suffered beside from a central scotoma, which seems to have assumed complementary colors. No difference between the eyes was discoverable by the ophthalmoscope.

By repeated examinations it appeared that the right eye perfectly distinguished colors, but that the left, with the polarizing prism, while it saw red and green correctly, perceived yellow and blue as red or pink and green or greenish. This eye must therefore, according to our present arrangement, be classed as blue-yellow blind. In this particular it is of special interest, even if we must consider the color-blindness as acquired, since acquired blue-yellow color-blindness has scarcely been observed.

Niemetschek connects the lesion of the left eye with a depression extending over the parietal bone and right half of the frontal, and caused by a former cavernous tumor.

The second case of unilateral color-blindness which is regarded as congenital seems also suspicious. Woinow³ observed in a lady of thirty-four years, with normal visual power and slight myopia, a peculiar dis-

¹ From Graef's Archiv, v. xxv. P. 2, 1879. Translated for the JOURNAL by J. F. Head, Surgeon United States Army.

² Prager Vierteljahrschrift, page 231.

³ Graef's Archiv, v. xxv. P. 2, p. 316.

turbance of color perception in the right eye. This, according to his examination, was green-blind, with a very pronounced photophobia, especially with regard to red colors. Whether this erythrophobia (*roth-furcht*), as he names it, affected one eye or both does not appear from his report. With the right eye alone the patient readily confused light green and dark pink (purple); all external objects appeared to her tinged with red; spectral yellow she designated as light blue. She was most comfortable with blue and bluish-green light. The visual field was also concentrically narrowed.

The patient had besides all sorts of hysterical sensations, and on the right parietal bone a depression of the size of a thaler, resulting from a fall six years before. To be sure, the photophobia and color-blindness would seem to have existed before the fall. Should we nevertheless be inclined to connect the color-blindness with this accident, it would be interesting to note that, unlike the preceding case, the injury was upon the same side as the color disturbance.

I had already, in the winter of 1873-74, had occasion to examine a girl, then twelve years of age, brought to me by her grandfather, who had remarked that with the left eye she could distinguish no colors at all, while with the right eye her color perception was perfectly normal. I examined the girl in the manner then customary with me, and particularly, as I will incidentally remark, with the worsted test, the color disk, etc. In company with Kirchhoff I also determined the limits of her spectrum, and the point of greatest brightness in it. It was then a matter of special interest with us to learn whether the physiological perception of brightness were the same in both eyes with equal illumination. For this purpose Kirchhoff constructed a binocular photometer so arranged that for comparison two strips of white paper, illuminated from the same source at different distances, were seen through a Wheatstone's stereoscope close together in the visual field. With this it appeared that the color-blind left eye required a stronger light to produce the sensation of equal brightness. By further experiments it seemed to be shown that the color seen with one eye differed from that seen with both. This surprising result led to the discontinuance of the examinations at that time.

A publication of Dr. Magnus in the *Ausland*, which the young lady's grandfather happened to read in the course of this winter, led him to communicate with our colleague of Breslau in relation to his granddaughter's peculiar faculties of color perception. I thus indirectly learned again the address of the girl, now grown to be a young lady. She as well as her grandfather had sufficient interest in the matter to permit a renewed accurate examination.

Miss L. S., seventeen years of age, comes of a family in which both unusually developed color-sense and also color-blindness have been observed. One of her mother's brothers is a celebrated artist in high repute as a colorist; another is color-blind. Her own color disturbance was discovered when Miss S. was a child of three years, by her asking her mother why the carpet, when she lay in bed upon her right side, had quite different colors from those which it showed when she lay on the left. As the pillow masked the eye of the side upon which she lay, the child saw only with the other. It could at that time be determined that in fact to the left eye everything appeared colorless. As the little one never before or since had any disease which usually produces disturbance of color perception, we

may conclude, with great probability, that the color-blindness of the left eye is congenital. The results of the more accurate examination reduce this to a certainty.

At present there is myopia of both eyes (right eye, myopia = D. 2.75; left eye, myopia = D. 3.00) with perfectly normal visual power ($V. = \frac{5}{5}$). Her hair is blonde, her iris grayish-blue; the young lady enjoys blooming health, and possesses more than ordinary intelligence. The ophthalmoscope shows absolutely no appreciable difference in the two eyes. The visual field is not contracted, and is of equal extent in both eyes; nor are any subjective perceptions of peculiar character announced. The distance between the pupils is fifty-six mm.

The examination of color perception gives the following: With a large Hoffmann's spectroscop *à vision directe*, the red end of the spectrum with each eye extends as far as with any normal eye. The blue end appears for the left eye to be a very little shortened, but the shortening is quite inconsiderable. The point of greatest brilliancy lies for the right eye somewhat to the right of the soda-line, for the left almost exactly in the soda-line. Through a green glass, the greatest brilliancy is moved somewhat to the right; a red glass does not change its position. By Stilling's method with colored shadows, red and green, as well as blue and yellow, are quickly and surely recognized with the right eye; with the left all shadows appear pure green, and are distinguished only by their degrees of darkness. These distinctions, however, are given with the greatest precision. Exactly the same results are obtained with the tissue paper, by Weber's method. The bright-colored letters, both red and blue, of the tables annexed to Stilling's Contributions, No. IV., Miss S. promptly recognizes at twenty feet and more. The tables of the new edition of Stilling's *Zur Prüfung des Farbensinnes* were also read; those adapted to blue-yellow blindness without any difficulty; those for red-green blindness with certainty, though somewhat more slowly. The letters and marks of the latter became very distinct when viewed through red glass; not so through green.

With Rose's colorimeter blue and orange, and also red and green, appear to her perfectly alike.

On Woitow's disk Miss S. recognizes only as respectively lighter and darker gray the colored rings which with the right eye she distinguishes quite correctly.

With Holmgren's worsted test she places with pure green other shades of green, flesh-color, bluish and yellowish greens, and pure red. Pale purple she matches with pure blue, purples of medium saturation, dark green, bluish green, and olive green; brick red with dark brown and bluish green, as well as with all colors containing any tinge of red. With this test it is highly interesting to observe Miss S.'s astonishment when the covered right eye is opened, and she is thus enabled herself to correct the errors which she has made. While with the right eye all the colors presented are distinguished, pointed out, and even named with the accuracy of a *virtuoso*, to the left eye everything appears only of a light or dark gray. It is very remarkable, however, that *brown* appears to the left eye as a color; indeed, this applies not only to worsteds, but to other stuffs, papers, oil and water colors.

The experiments with Maxwell's disks show that the left eye not only perceives as such all the matches for normal eyes, but that to any given gray a match

can be produced from two, three, or several colors at will, provided only that the right degree of saturation be hit. It is therefore of no interest to give the numerical values of the color matches obtained.

The experiments in binocular vision were specially interesting with reference to the results obtained in 1874. Ability to realize solid effects from stereoscopic pictures exists in a high degree. There is a surprising result, too, in the lustre tests.¹ If to the left eye be presented a red surface and to the other a blue, and then *vice versa*, in the first case blue alone and in the second red only is perceived; the same is the case with green and blue. And yet in all these tests an influence of binocular vision can be appreciated. That is to say, if the color presented to the left eye, whether red, blue, or green, be lighter than the color presented to the right eye, the color seen with both eyes is lighter than when the left eye is closed. As a check test, first gray and then black before the left eye were added to the blue before the right. The effect was in the first case a lighter, in the second a darker, blue.

Finally, I examined the differentiating power² of each eye separately and of both together by means of Massou's disk, and not only by rotating black strips on white disks and white on black, but with yellow on blue and green on red, and *vice versa*. From this it appeared that the distinguishing power of the left eye for black amounted to about $\frac{1}{15}$, that of the right eye to about $\frac{1}{15.5}$, and the binocular differentiation to about $\frac{1}{15.6}$. Compared with my own eyes, the amount for Miss S.'s right eye agrees with that of each of mine; but, on the other hand, my binocular distinguishing power is considerably greater, about $\frac{1}{15.5}$. Hence it is evident that the diminution of light perception in the left eye has a most precisely appreciable effect in binocular vision. The differentiating power found is greater than that elsewhere given.³

I propose to publish in another place, with further experiments, the more exact data regarding the separate series of examinations.

From all the foregoing there can be no doubt that in this case we have to do with congenital unilateral total color-blindness. I refrain from entering upon a detailed discussion of the facts reported, but yet will remark that the effect of binocular vision upon the color perception observed five years ago is fully explained by the renewed examination. The difference is not in the color, but in the shade of which it appears.

Since the occurrence of congenital unilateral color-blindness is established by this case, its rarity appears to me only the more doubtful. It is supposable that many cases have been overlooked, because both eyes are usually examined together as to their color perception.

As the subject of this case is a young lady from a family in whose male members also color-blindness occurs, the special examination for unilateral color-blindness of the female members of those families in whose male branches the occurrence of color-blindness has been ascertained should commend itself. Possibly we may thus find the key to the enigmatical overlapping of congenital color-blindness from the grandfather to the sons of a daughter not color-blind.

Reports of Societies.

PROCEEDINGS OF THE OBSTETRICAL SOCIETY OF BOSTON.

C. W. SWAN, M. D., SECRETARY.

A NEW INSTRUMENT FOR THE READY, EFFECTIVE TREATMENT AND PREVENTION OF BLOOD-POISONING IN SURGICAL OPERATIONS.

JUNE 14, 1879. DR. BIXBY exhibited the instrument, his own device, and read a paper embracing observations upon the subjects of pyæmia and septicæmia in surgical and other cases, with examples illustrating the use and value of the instrument. The paper will be published.

UTERINE AND VAGINAL INJECTIONS.

DR. RICHARDSON said that he agreed with Dr. Bixby as to the use of intra-vaginal injections. For the past six months in the Lying-In Hospital these had been the invariable rule in all cases where there seemed to be evidence of any septic absorption. Winckel claimed that a rise of temperature in some cases indicated absorption of poisonous matter from some solution of continuity along the vaginal tract; these points being sought out and touched with caustic the trouble would cease. Vaginal injections should be employed to avoid that absorption which, in Dr. Richardson's opinion, was one of the causes of puerperal fever. At the same time there is a liability to absorption at the placental site, or at some other part within the internal os. In a specimen which Dr. Richardson had shown to the society in the winter, there was a marked difference between the mucous membrane of the cervix and that of the body of the uterus, the former being perfectly healthy, while the latter, separated by a sharp line of demarkation, was seen to be broken down. Should a chill occur, especially with a marked elevation of temperature, he would at once resort to intra-uterine injections. He had seen the greatest benefit result from them, a temperature of 103° to 106° F. falling in two or three hours to 100° F., and again, if recurrence. The injection used was a mixture of carbolic acid and water, one part to ninety, used as hot as the patient could comfortably bear it, — about 116° F., — and in large quantity, or until the fluid came away clean, and repeated according to the symptoms, generally three or four times a day for two or three days, when, if there were no recurrence, they have been gradually left off. The injection has been made through a tube corresponding in shape to a male catheter, but perforated near its end with numerous small holes spirally arranged, for the better dispersion of the fluid; but should the os not be freely patulous a double catheter should be substituted. It is very rarely that there is not a decided fall of temperature within two or three hours after an injection, frequently not to rise again. Sometimes, perhaps in half the cases, the temperature will again go up, and the process will require to be repeated accordingly. Dr. Richardson stated that he did not use intra-uterine injections without special symptoms, but in case there were an offensive lochial discharge, with a rise in temperature which was not accounted for by the coming of the milk, such injections would be indicated. Vaginal injections, on the other hand, he used in all cases, both in hospital and private practice, as a preventive measure. Three

months ago very high temperatures were running at the Lying-In Hospital, and vaginal injections had, as it happened, been interrupted for some time. The injections were renewed, and the temperatures all fell again within two weeks.

Dr. C. E. STEDMAN remarked that he had just finished attendance upon a case of labor in which the pulse rose to 130 and the temperature to 104° F. There had been no vomiting, chill, nor offensive lochia, neither was there cause for alarm, as Dr. Stedman had conducted the patient through very severe labors before in which similar phenomena, which were simply peculiar to the patient, had appeared.

A healthy patient whom Dr. Stedman had delivered a month ago complained upon the third day that something was protruding from the vagina. A long string of membranes was extracted, entirely free from odor. No injections had been used; no harm resulted.

Dr. BIXBY remarked that in an extreme case of puerperal fever, as well as after the removal of intra-uterine fibroids, it would be desirable to establish a constant irrigation of the uterine cavity.

Dr. RICHARDSON agreed that that would be the perfection of treatment if it could be made practicable. In this connection he spoke with approval of a bed-pan in regular use at the Lying-In Hospital, the invention of Dr. Joseph Stedman. Its advantage consists in a nozzle for the attachment of a rubber waste-pipe.

Dr. LYMAN held that a woman should have a clean vagina as well as clean face and hands, and that vaginal injections should be used as a matter of cleanliness as well as a safeguard against possible infection.

Dr. RICHARDSON said that we should use them on account of possible fissures along the course of the vagina, and because we do not know when we are going to have trouble and when not. Of course to completely carry out this idea of antiseptic obstetrics, we should use intra-uterine injections also, so as to avoid the danger of absorption within the uterus, but with our present appliances and lack of skilled nurses he did not consider that method safe, except where danger actually threatened.

Dr. SINCLAIR said that he had very little to add to what had already been stated. At a previous meeting he had read a case of death from septicæmia occasioned by a decomposing clot and portion of membranes in the uterus. At the autopsy he felt that life might have been saved had uterine injections been employed. In his last three months of service at the Lying-In Hospital eight or nine cases of septicæmia had occurred, and the situation was alarming. Vaginal injections were dropped to diminish the chance of carrying the disease from one patient to another. The use of intra-uterine injections of permanganate of potash, from once or twice daily to once every three or four hours, was instituted for the first time, and lives were undoubtedly saved by the procedure. The adjuncts employed were quinia, beef essence, and brandy, and sponging with diluted alcohol. One patient, who was extremely low, consumed a bottle of brandy daily without intoxicating effect, and she took in all, daily, eighty grains of quinine and an equal amount of salicylic acid.

Dr. STEDMAN said that in the case recently read by him before the society, there was no doubt that life was saved by intra-uterine injections. The temperature went down at least two degrees after each injection.

Dr. RICHARDSON, in answer to questions by Dr.

Boardman, stated that he had never observed any fall or variation of temperature whatever from the use of vaginal injections which were as hot as the others.

Dr. HOSMER asked Dr. Hodgdon whether his puerperal patients were usually free from offensive lochial discharge. Dr. Hodgdon replied in the affirmative. Dr. Hosmer stated that his standing direction to the nurse was to administer a catholic injection *whenever* (every hour if necessary) the lochial discharge gives rise to the least unnatural odor. He supposed that Dr. Hodgdon simply intended to say that his experience had included a period (now passed by) in which cases with bad symptoms were presenting themselves in rapid succession.

Dr. SINCLAIR said that if the lochial odor became foul, one would find a fall of temperature.

Dr. INGALLS remarked that foul odors were especially obnoxious to him, and that he was quick to perceive them. Of late years he had very rarely had offensive discharges after delivery in his cases, and he had never been obliged to inject the uterus. The vagina has to be kept clean quite often, indeed, always. He had never had a case of puerperal fever, but had seen several in consultation. For that matter, out of two thousand cases he had never had a placenta prævia, and but three cases of convulsions.

Dr. ABBOT stated that he had never even seen a case of puerperal fever.

A CASE OF PUERPERAL CONVULSIONS WITH ALBUMINURIA, IN A PRIMIPARA AT THE SEVENTH MONTH OF PREGNANCY; PREMATURE DELIVERY BY MANUAL DILATATION OF THE CERVIX; CYSTITIS; DEATH FROM UREMIA ON THE SIXTEENTH DAY.

Dr. SINCLAIR reported the case as follows:—

Mrs. —, seen in consultation on May 24, 1879, with three other physicians, one of whom was the husband of the patient, had substantially the following history: Age twenty-two, married eighteen months, never strong, said to be advanced seven months in her first pregnancy. Her health was sufficiently good until the end of the sixth month, when she developed signs of renal disease, with extensive oedema, for which she was treated. The swelling disappeared from the face and extremities, but not the albumen from the urine. In the midst of this apparent improvement she was suddenly seized with convulsions, which recurred frequently and severely. Consciousness became less and less. She was treated by cathartics and enemata, and the paroxysms somewhat mitigated by the inhalation of ether. Urine taken from her bladder at the time of my visit became nearly solid on heating. She was sufficiently conscious to make resistance to the use of the catheter. In conference with the gentlemen already referred to, who had watched the case from the beginning, it was agreed that premature delivery was justifiable, and it was effected in one hour and three quarters by manual dilatation of the cervix. The child was turned, was still-born, but was alive when first touched in utero. It was small. There was no injury done to the soft parts, and ether was given during the process of delivery. There was no unusual flow, and the uterus contracted normally.

About an hour after the uterus was emptied she became extremely restless, turning from one side to the other every minute; pulse rapid, temperature 101° F. This disagreeable condition was quieted by opium, and she rested calmly for several hours. During the fol-

lowing day (25th) she became somewhat more conscious, and it was then observed that she was blind. Abdomen tympanitic. The subsequent behavior of the case is given from report. On the 26th, the tympany was less. Vaginal douches of carbolyzed tepid water were commenced; lochia natural; blindness continues; seems to comprehend when spoken to. One and a half pints of urine, by catheter. Density 1020. Albumen one eighth; hyaline and granular casts. 27th. Pulse 96, temperature 101° F. More conscious; eyes the same; flatulency; less tenderness of abdomen. Urine the same. Takes food more readily. 28th. Two pints of urine by catheter. Some tenderness of abdomen on pressure; lochia well; sight returning; recognizes family and physicians. 29th. About the same. 30th. Two pints of urine by catheter in twelve hours; odor disagreeable. Albumen one half. Microscopically as on 26th. Pulse 100. Milk in breasts. June 4th. Soon after a vaginal injection there came suddenly a flow of blood from the vagina to the extent of six ounces. Pulse 110. Ergot was given, and a tampon used. 6th. One pint of urine withdrawn in nine hours. Density 1010. Albumen one fifteenth. 7th. Very comfortable, but the temperature 102° F. Urine one and one third pints in eleven hours. Albumen one twentieth; slight mucous deposit. 8th. Urine, one and a half pints in eleven hours. Milky appearance; putrescent deposit of mucus. Nine p. m. Recurrence of hæmorrhage from the vagina. 9th. Urine withdrawn; one half pint in twelve hours; cloudy, putrescent, alkaline. Albumen one sixth; disintegrated granular casts. Pulse 128, temperature 101° F. 10th. Had a comfortable night. At ten o'clock, A. M., pulse 134, feeble; slight hæmorrhage from vagina; vomited for the first time this A. M., and several times during the day. 3.30 p. m. Pulse intermittent. Sinking. Jactitation. Sighing. Died at 5.45 o'clock. P. M.

On review of this case my reporter stated that the temperature ranged from 100° to 102.5° F., and the pulse from 100 to 112 until the day before her death, when it mounted higher; that she took and retained food, and seemed to gain until the 9th, or even later, when she suddenly collapsed. The flowing was not profuse at any time, the whole loss not exceeding eight to ten ounces. The albumen in the urine diminished after delivery, then gradually increased until the time of the hæmorrhage, when it again diminished. The uterus was well contracted at time of death.

Dr. SINCLAIR remarked that he thought he could dilate the os uteri with the hand without abrading the mucous membrane.

Dr. LYMAN questioned the possibility of doing this (dilating the os without abrading the mucous membrane).

Dr. CURTIS stated that he had been present at an autopsy in a case in which he had manually dilated the os, and delivered by turning three days before. No abrasion could be discovered.

Dr. LYMAN said he thought it quite possible to overlook a superficial abrasion, which might indeed leave no trace, and yet have been sufficient for the reception of septic matter.

Dr. STEEDMAN observed that in Dr. Sinclair's case it seemed hardly necessary to go back to septicæmia to account for the death. In cases of Bright's disease patients sometimes do go off suddenly, it is difficult to say why, as in the case of a patient who was suffer-

ing from amyloid disease of the kidneys and other organs, and who, after conversing as usual with a number of people, suddenly died. She had passed a sufficient quantity of urine. Her temperature frequently rose in the course of the day to 102° F.

RECTAL SPECULUM.

Dr. HOSMER exhibited a recent modification of his rectal speculum. The improvement consists in the fact that the narrower mirror can be so placed as to make a larger angle with the axis of the instrument, and at the same time leave a larger aperture for the admission of light. The larger angle alluded to very much aids inspection.

Dr. RICHARDSON said that he had used the speculum in its original form. As changed it works admirably. Looking into the mirror one is entirely out of the way of the light.

PROCEEDINGS OF THE BOSTON SOCIETY FOR MEDICAL IMPROVEMENT.

T. M. ROTCH, M. D., SECRETARY.

APRIL 26, 1880. Dr. JAMES C. WHITE, permanent chairman, presided.

SUDDEN AND TRANSIENT SWELLINGS OF THE LIPS.

Dr. T. B. CURTIS read a paper on this subject, which he reserved for separate publication.

Dr. C. B. PORTER said that he could corroborate the statements made by Dr. Curtis in his paper from his personal experience in three cases. They were all adults. In two cases the upper lip was the seat of the swelling, and in the other the lower. The notes taken in one of the cases state that he was a healthy man, aged thirty-seven years; he had not had a sick day for twenty-five years. He retired to bed with an uncomfortable stiff feeling in the upper lip, but without marked swelling. He was awakened in the night by a sensation of discomfort and tension of the lip, and on rising and looking in the mirror he was alarmed by the hideous expression of his face, the upper lip being enormously swollen, so as to overhang the under one. Early in the morning he consulted a dentist, thinking to cruminate his teeth as a cause of his disfigurement. No trouble with them was found, and he was recommended to come to Dr. Porter. The swelling involved the whole upper lip, gradually losing itself in the cheeks, and being symmetrical. There was no heat, no pain, no redness, only the great discomfort and disfigurement produced by its size. He was advised to do nothing and to wait, as there was no indication for treatment. He followed this advice, and during the afternoon the manifestation commenced to disappear, and by the next morning there was no evidence of the swelling of the previous day. He had never had urticaria. The condition seemed to be simple œdema, but of the cause of the same Dr. Porter had no knowledge. He considered no treatment necessary, unless the distress of mind caused by the disfigurement might make a placebo desirable. The other two cases were similar, but he had no notes of them, and did not remember the duration of the trouble, but only its fleeting character.

Dr. BRADFORD mentioned having seen five cases, all of the lower lip but one. The patients were all adults under thirty, except one, a child of fourteen. The symptoms were exactly those described by Dr. Curtis, except that there was no tenderness or heat.

Dr. J. P. OLIVER had seen a number of cases in children, especially in the spring, and among the poorer classes rather than the wealthy.

Dr. EDES said that this paper threw much light upon a case occurring in a professional brother, where great swelling of both lips took place without known cause, and subsided in a few days, though less rapidly than in Dr. Curtis's cases. He had also seen a rapidly developed swelling of the whole face in a young woman, and a swelling of one half the tongue in an old man, which he supposed to be of the same character. He thought the swelling to be oedematous, and suggested that the reason why the same pitting found in other localities cannot so easily be produced in the lips might be due to their structure, that is, the absence of a subcutaneous layer of lax cellular tissue. In some cases of old dropsy, where the skin itself as well as the subcutaneous cellular tissue contains fluid, it requires considerable pressure to produce much pitting.

Dr. BOLLES felt obliged to Dr. Curtis for so carefully studying this neglected but not very uncommon affection, and could testify from a few cases which he himself had seen to the accuracy of his descriptions. The short duration, the great and ludicrous deformity, the absence of pain and tenderness, characterized all his (Dr. Bolles's) cases also; but these very circumstances made it difficult for him to recognize any inflammatory character in them, and he was inclined to agree with Dr. Edes as to their principally oedematous nature. He also believed that the cause would often be found to be a local one.

Dr. WADSWORTH said he had once observed the affection in his own person when fourteen or fifteen years old, being at the time in very good health. The swelling appeared in the afternoon in the lower lip, was attended with some feeling of numbness, and passed off, or nearly passed off, before bed-time. He wished particularly, however, to refer to certain cases in which there was rapid oedema of the upper lid and chemosis of the conjunctiva, and which he thought were of the same nature as those described by Dr. Curtis. He had seen perhaps half a dozen such cases. They were all in adults, all occurred in hot weather, and the swelling was first noticed on waking in the morning. In every case the oedema and chemosis mostly disappeared in the course of twenty-four hours under the application of ice compresses, which treatment he had always advised. At the first glance these cases suggested the commencement of a violent purulent ophthalmia, but there was no redness of the skin, very little conjunctival congestion, and no mucus, even scarcely increased watery secretion.

Dr. CURTIS said that if this was an oedematous condition of the lips it was rather curious that the lips should not swell after an operation had been performed on them, as is the case with the eyelids. — Dr. BOLLES remarked that the lips do at times swell considerably from a blow, perhaps where the tooth cuts the inside of the lip. — Dr. WADSWORTH said that it was also rare for the eyelids to become oedematous after operations.

Dr. WHITE related the case of a gentleman who, while undergoing some dental operation one afternoon, noticed that a swelling suddenly appeared above his left eye. It reached at once so alarming a size that he came immediately to Dr. White for advice. The tumor then (within half an hour of its beginning) was as large as a goose egg, occupying the whole left side of the forehead and nearly closing the left eye. The skin cover-

ing it was tense, but otherwise unchanged. There was no alteration of temperature or in the sensations of the part excepting the strangeness of its presence. He considered it to be a form of so-called giant urticaria, and assured the patient that it would quickly disappear. Cold evaporating lotions were advised, and on the following morning the swelling had wholly disappeared. Dr. White regarded this term "giant urticaria" as well applied in such cases, because it seemed to him that the anatomical changes were identical with those in ordinary urticaria. He had, in fact, seen similar developments in two patients with ordinary chronic nettle-rash, swellings as large as small hen's eggs, which ran the same course as those described by the reader and preceding speakers. He considered the process in no sense inflammatory, but as a sudden and violent oedema affecting the deeper corium and subcutaneous tissues, and presenting, except in its seat, the same phenomena of evolution and involution as the simple wheal. It seemed impossible to explain it in any other way.

PECULIAR AFFECTION OF OCULAR MUSCLES.

Dr. WADSWORTH reported a case of peculiar affection of the ocular muscles. A week ago a youth of sixteen came to him with the complaint that he was unable to turn either eye toward the left. On examination, it appeared that when an effort was made to turn the eyes toward the left they moved scarcely, if at all, beyond the median line. Sometimes with such effort there was a slight movement of the eyes upward and downward, similar to that which is seen with paralysis of an ocular muscle when other muscles attempt to assume its function.

If, however, the eyes were directed to an object in front they could be maintained in this position while the head was rotated toward the right, so that, in consequence of the rotation of the head, they came to assume in regard to it the same position they would have had if they had been turned strongly to the left while the head remained quiet; or, the head and eyes, the latter being in the median position, could be turned to the left, and then the head rotated to the front again, leaving the eyes still looking to the left. In all other directions the movements of the eyes were normal, nor did there seem to be any disturbance of function other than that described.

It was learned on inquiry that the patient had worked in a nail factory since eight years of age, the last few years having been employed in feeding iron plates to the machine that cut the nails. About the first of March last he began work at another factory, making much smaller nails than before. At his new work he was obliged to watch intently the machine some two feet in front of him, while directing the iron plate with his hands. There was also in front and to his left a pile of hot plates, so near as often to be very troublesome and lead him to turn his head far to the right to screen his face from the heat as much as possible. It was since this change in work that the affection of the eyes had come on.

To explain satisfactorily the phenomenon here observed is not easy. But it is perhaps reasonable to suppose that the continued strain to which the muscles acting to turn the eyes to the left were subjected, on account of the twisted position of the head while at work, excited after a time a certain rigidity of the other ocular muscles also. So that, finally, whenever an attempt was made to turn the eyes to the left all the oc-

ular muscles contracted, or so many of them as sufficed to keep the globe immovable or nearly so. That this explanation is not wholly sufficient is readily admitted.

ABSCESS OF THE BRAIN.

DR. EDES showed a specimen of abscess of the brain from a case with the following history:—

A young man fell from a coal staging, striking upon the right side of the head and face; was unconscious for ten minutes.

Upon entering the City Hospital, February 9th, no fracture of the skull was discovered. The facial bones seemed to be movable, but there was no crepitus. There was ecchymosis of the eyelids.

February 11th. Rational and free from pain.

February 17th. Stiffness of limbs and pain at base of skull.

February 22d. Comfortable, but drowsy and apathetic.

March 6th. Discharged relieved. At this time pupils of right lid dilated pupil. At home is said to have been sulky and morose, instead of cheerful, as usual. Vomited a good deal.

Reëntered hospital March 17th, insensible. Had had a "bad spell." Face and hands congested and cold. Respiration 37; pulse 137; breathing difficult. From this condition he soon recovered.

Urine 1022. Albumen present. Many casts.

After this time the symptoms were chiefly drowsiness and disinclination to talk. At times severe headache not distinctly localized, and gradually developed pains of the left side of the face and left hand. At times the right pupil was dilated, and for a few days there was a decided protrusion of the right eyeball and a little swelling of the lid. The head was turned to the right and an attempt to turn it to the left was attended with considerable pain.

The urine became normal a few days before his death; there was no decided difference in the temperature of the two temples; he died April 26th.

The autopsy disclosed the frontal lobe of the right side greatly distended and fluctuating. The convolutions were flattened, and adherent at one point on the lower surface to the alba mater and to the orbital plate of the frontal bone.

An incision showed an abscess with a very well-defined capsule, holding perhaps 100 cc. of green pus. It extended inward to the wall of, but did not perforate, the lateral ventricle. It did not involve the great ganglia, unless possibly the very anterior border of the nucleus lenticularis. The lower was very thin, but above and externally to the capsule there was a tolerably thick layer of comparatively normal brain substance. Through the orbital plate of the frontal bone, at the point of adhesion, extended a small hole with irregularly tilted edges, apparently a united fracture. The tissues of the orbit showed no trace of inflammation. In this case, had the exact relation of the abscess to the roof of the orbit been known it would have been possible to empty it through the orbit. The reporter asked whether any instance was known of an opening being made into a cerebral abscess, guided by a diagnosis based on symptoms alone and without visible external injury.

OVARIAN CYST.

DR. JOHN HOMANS showed an ovarian cyst removed ten days before from a lady forty-seven years

old. It was from the left ovary, and was without adhesions. The operation lasted about twenty minutes, was done under the spray, and the pedicle, after ligation, was cut through with Paquelin's thermo-cautery. No opiate has been given since the operation, and the patient is now, apparently, perfectly well. Dr. Homans remarked that in his last two cases he had cut through the pedicle with the cautery, and thought this method superior to that of the knife or scissors.

OPERATING TABLE.

DR. HOMANS also exhibited an operating table for ovariectomy, and said that it was sometimes desirable during an ovariectomy to turn a patient more or less completely on her side. This becomes necessary when the cyst is very friable, or has been ruptured since the operation was begun, and consequently there is great difficulty in keeping the cystic fluid from running into the abdominal cavity. With the patient on her back any fluid that may be leaking around the clamp or running out from a laceration in the cyst gravitates into the abdominal cavity; the operator then calls upon his assistants or some of the spectators to turn the patient towards him. Now, however willing and strong the assistants may be, there is a slight feeling of uncertainty as to whether one of them may not become fatigued, and allow the patient to slip or fall back. A patient placed on this board, which is eighteen inches wide and has an iron trunnion or axle at either end, like the trunnions of a cannon, is securely strapped thereto, and when it becomes necessary to turn her on the board, with her on it, is rotated by means of a lever attached to a cog-wheel, and by dropping the pall the patient may be kept as long as desirable in any position and at any angle. These little tables support the board at either end, and when not in use fold up. There are two dovetail-pins beneath the table at either end, which drop into holes in the tables, and thus prevent the board from slipping. When the operation is finished the board is lifted out of its sockets at either end, and the patient is carried to her bed. This new operating table will probably soon be described more at length, with explanatory drawings.

Recent Literature.

The Student's Manual of Venereal Diseases. Being the University Lectures delivered at Charity Hospital, B. L., during the Winter Session of 1879-80. By F. R. STURGIS, M. D., etc., New York: G. P. Putnam's Sons. 1880. Pp. 196.

"Audacious self-esteem, when well grounded, is imposing," says the Autocrat. "The Student's Manual" it is, and the student's manual it is to be. The cardinal points of a manual are clearness, conciseness, comprehensiveness, and correctness, and these are the marked and characteristic qualities of the little book we are considering. It is plain even to bluntness, thoroughly practical, and in every way on a level with the best knowledge of the day upon the subjects of which it treats, though a somewhat quaint and *bris-a-brac* aspect is imparted to it by the exclusive use of the systemless system of weights and measures "of the forefathers," which, supported by *selich vis inertia* and indolent conservatism, is now rapidly half tottering, half sneaking, "down the back entry of time." Dr. Sturgis has cast his little book upon the waters "to

take its chances," asking only "candid criticism, and that if the work be worthless it may be damned, the sooner the better." "Candid criticism" is all we have to offer; it shall not be our fault if the world do not find it, and that before many days. We have rarely been so interested in any book. Mooted points are carefully omitted, proved ones are insisted upon; errors are exploded, while vital truths are given in the excellent form of italicized mnemonic axioms. It is *par excellence* the manual, not only for the students *in posse* of the schools, but also for those *in esse*, the actual practitioners of town or country, now for the first time perhaps read students under the inflexible task-master necessity.

The results of treatment obtained by Dr. Sturgis after the use of particular remedies have varied somewhat from those attained by us with the same medications, in plus and in minus degrees. But we are no sticklers for absolute superiority in any hobby, our own or another's. Too much depends upon how he is handled. Varying uses of different means give identical results, just as varying uses of the same means give diverse results. The effects upon the "poor wayfarer man of grief" of lightning from aloft or a volcanic eruption from below may be the same; but should he escape these perils, and, taking his ease in his inn, give a horizontal rather than a vertical sweep to his razor, his jugular would suffer rather than his whiskers.

Apart from the "treatment," which is excellent, and, as a whole, hardly to be improved upon, we call attention to the value in particular of two chapters, namely, that upon Syphilis of Special Organs and the one upon Syphilis of the Nervous System and of Bone. We would notice also, and specially commend, the adoption by the writer of the German plan of parallel tables with comparison of symptoms, for the purpose of fixing in mind points of differential diagnosis. Furthermore, we agree to and approve of, as true, certain italicized sentences, and profit by this opportunity to cite some of them for the instruction of our readers: "Nitrate of silver is not a caustic; do not use it as such; it stimulates, but does not de-roy." "The initial lesion of syphilis may be soft." "A chancreoid is dangerous up to the very moment of its complete cicatrization." Syphilis begins "always by an initial lesion, seated at the point where the virus gained entrance," and "no portion of the body is exempt from being the seat of the initial lesion." "Do not cauterize an initial lesion unless phagedenic." "Do not treat the initial lesion by the internal use of mercury, but await the development of secondary symptoms." "Paralysis of single muscles, or sets of muscles, is, nine times in ten, syphilitic." "Never, under any circumstances, open a gunnison enlargement of bone or gland, no matter how soft it gets." "Mercury is the main-stay in treatment." "Iodide of potassium is of little service in the earlier stages." "Do not hesitate to use either remedy in sufficient amount to dispel the symptoms, no matter what the requisite dose may be." The writer gave, with success in ten days, in a case of nervous syphilis, eight grammes [grains cxx.], three times a day, of iodide of potassium. "The average case of syphilis runs its course in from eighteen to twenty-four months. Under proper and careful treatment, the graver forms of the disease seldom occur. After suspending treatment, keep the patient under observation another eighteen months" before pronouncing him well; that is, three to three and one half years in all of supervision *before*

the patient may marry. "I protest against names for the syphilodermata, borrowed from the slight resemblance they have to the corresponding non-syphilitic eruptions of the skin." "The terms secondary and tertiary are ones of mere convenience, not to be accepted as purely chronological. I prefer to speak of these lesions as superficial and deep." "I call the first symptom of syphilis the initial lesion, and entirely abandon the word chancre." "Call the chancreoid the simple venereal ulcer, if you do not wish to use the word chancreoid." "Gonorrhoea does not depend upon a virus; it is a simple catarrh of the urethral mucous membrane, and is due to the presence, within the canal, of some local irritant." "Urethritis in the female is always due to some venereal affection." "Syringes made of vulcanized rubber are the only ones fit to be used, and some of these are objectionable from their inordinately long nozzle. The best are those which terminate in a cone." "In taking an injection, a woman should lie on her back, not merely squat down." "Glass and hard-rubber vaginal syringes are of no use." In clasp "a discharge is sometimes kept up by over-medication." In gonorrhoeal ophthalmia "remember never to put the leeches on the eyelids." It will be seen that Dr. Sturgis has adopted the only true and scientific nomenclature. Instead of the erroneously so-called gonorrhoea, he would say urethritis, vulvitis, balanitis, etc. Instead of the "so-called chancreoid" he would say simple venereal ulcer. Instead of the so-called chancre he uses the term initial lesion of syphilis, or primary sclerosis, — in all of which we most heartily agree with him.

Students and physicians, *buy this book!* Do not merely take it from the library. It is cheap, it is complete, it is correct. It will be long before another book of the kind need appear to enter into competition with this one, which entirely supplies a long-felt need. E. W.

A Few Cases of Leprosy. By J. H. BEMISS, M. D., Lahaina, Maui, H. I. Reprinted from the April number of the New Orleans Medical and Surgical Journal. New Orleans: L. Graham, Steam Book Printer, 127 Gravier Street. 1880. Pp. 16.

This little pamphlet contains twelve wood-cuts, representing very fairly cases of leprous disease the histories of which were taken either by the writer or by some friend. As to the time and manner of introduction of leprosy into the Hawaiian Islands, Dr. Bemiss sets the period at about the year 1825-30, and believes that the disease was imported from without. A generation later the cases were so numerous that the government established a leper hospital at Molokai. The writer recognizes tubercular and anæsthetic leprosy, but does not feel warranted in recognizing macular leprosy as a third variety. Leprosy has nothing to do with syphilis, is hereditary but not contagious, unless possibly by the direct introduction of its virus into the blood, as, for example, by inoculation. Treatment is merely palliative, though amelioration has followed the use of Hoàng Nân pills.

— On the 22d of April Miss Sara Van Buren, a daughter of Prof. William H. Van Buren, and granddaughter of the late Valentine Mott, was married to Mr. Jules E. Biagière, of New York, at Dr. Van Buren's county-seat, at Shrewsbury, New Jersey.

Medical and Surgical Journal.

THURSDAY, MAY 6, 1880.

A Journal of Medicine, Surgery, and Allied Sciences, published weekly by Houghton, Mifflin and Company, Boston. Price, 15 cents a number; \$5.00 a year, including postage.

All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.

Remittances by mail should be sent by money-order, draft, or registered letter to Houghton, Mifflin and Company, Boston, Mass.

INSANE ASYLUMS IN THE UNITED STATES.

In the evolution of the insane asylum of the past from a place of custody for lunatics to the modern hospital for the cure of mental disease, and in the progress of the study of insanity from the curiosity of metaphysicians and terror of the populace to its proper place in medical science as an exact branch of knowledge, the United States, we regret to say, have taken so little part, so far as recent advances are concerned, that our latest foreign critic has scarcely more than repeated Dr. Bucknill's sharp and to a considerable extent deserved criticism in saying, "*If I had not been aware of the fact, I should hardly become cognizant of it here [in America], that psychiatry has gradually developed into a respectable science, which, like all sciences, must be taught and learned.*"¹

Dr. von den Steinen spent the greater part of his time, while with us, in New York, and observed the asylums of that State with a considerable degree of care. He complains of the extravagant "palace prisons" as unnecessarily jail-like and cruel, of the great overcrowding and lack of attendants,² and of the excessive amount of mechanical restraint and seclusion, with the correlative evil of want of employment, curiously enough repeating Dr. Bucknill's very word, "menagerie," in referring to some of the cage-like arrangements seen by him. He meets the objections of our superintendents to the employment of the chronic insane on the ground that they cannot be got to work by showing how much has been done in that direction for even a more hopeless class of cases, namely, idiots. Dr. von den Steinen says that non-restraint and employment must go hand in hand, and continues, "When I mention the fact that under unfavorable conditions absolutely no restraint is exercised on the considerable number of refractory patients in the Charité Krankenhaus, at Berlin. I am always certain of meeting somewhat dubious faces, and invariably receive the answer, 'But in our experience we have found that in a certain number of cases [which, however, are always to be met with] it is impossible without restraint to prevent patients from injuring either themselves or others, and our apparatus is the best adapted for that purpose.' I must frankly confess that, in my opinion, they have no such experience as they believe themselves entitled to claim. The non-restraint

system cannot be subjected to many experiments; it must either be rejected or accepted; the essence, the nature and secret, of it is its unconditional application. The transitory stage at which you stop includes the greatest difficulties; truce is not peace, but war. When you become doubtful of success, you put on the jacket again, but you cannot get along without it until you have none to use. Do not believe that we allow our patients to be abused by the fists of attendants and have their ribs broken; do not suppose that we poison them by substituting chemical restraint, or, as Neumann has ingeniously termed it, 'the restraint of the pedunculi'; and, lastly, do not believe—for the contrary would be correct—that the number of suicides is greater than in your asylums. But still we do not require your means of restraint, because we are not in possession of them, and because we possess naught but a single jacket that serves to demonstrate to the students the method formerly in practice. But something else is true: when the new system was introduced in the Charité, all the attendants, with the exception of one or two, had to be dismissed. Neither physicians nor attendants should know that a system of restraint is in existence. In this point is involved as well the only possibility of solving the task, as the greatest benefit of treatment. The asylum undergoes an entire change. A superintendent of very humane principles told me that he never employed crabs, although they might be of service at times, because if he had one the attendants would demand more. And so it is. Restraint serves to insure the comfort of the attendants, while now they are compelled to treat free patients kindly and deferentially to accomplish those results that were formerly obtained by force.

"In the better asylums I did not observe any of the cruelties for which they are reproached; but I did notice in all instances that the patients sat downcast in their chairs while the nurse was attending to his private affairs. In no case have I seen a ward for violent cases where the attendants were really intent upon subduing the excitement of the patient by kindly and intelligently adapting themselves to his humor. . . . It cannot be too often impressed on the minds of attendants that they are dealing with *patients*; this simple truth, which we so fully understand, they are unable to comprehend, when these so-called patients are bound. . . . We must admit free treatment is not possible when the corps of nurses is deficient in the qualities requisite. Nothing is more lamentable; for the nurses constitute a part of the therapeutic appliances of the asylums, as bandages form part of the therapeutics of the surgical hospital. But there are a number of institutions where this fault has not to be overcome, and where restraint is nevertheless retained. . . . There may be cases where it would be indifferent, from the stand-point of humanity, whether weak and violent patients were secured or not; but I cannot emphasize too strongly that the value of strict non-restraint will be experienced from the wholesome influence it exerts on the hospital in general, and that even the few cases of restraint existing should be abolished; two discordant notes will spoil the effect of an

¹ A letter on American Asylums for the Insane, by Dr. von den Steinen, of Berlin, in reply to a request by Dr. E. C. Seguin, reprinted from the Archives of Medicine, vol. iii, No. 2, April, 1880.

² In the Charité, where he was trained, there is one attendant to every three patients, from three to five times as many in our public hospitals for the insane.

entire piece of music. Free treatment is the only means of insuring real medical observation and of transforming the institute of detention into a hospital."

It is a curious fact that some of the Germans unconsciously even Conolly in their rejection of mechanical restraint, most English superintendents using it very rarely indeed, as has been their custom for many years, and then as a very uncommon exception to an all but rigid rule.

The paper continues:—

"The superintendent is fully taken up by administrative duties, and has not the opportunity of instructing his assistants and letting them profit by his practical experience. Nowadays no trade is learned autodidactically, much less a science. . . . Without sufficient education neither pathological nor clinical results can be attained. I do not wish to criticise the reports, which often give proof of very confused ideas in regard to the classification of mental diseases, but I was often astonished to . . . find that even so plain a disease as general paralysis is so insufficiently known as I have constantly had occasion to observe. I wish to know the number of paralytics, and after a hasty visit I ascertain as many more as have been reported."

Dr. von den Steinen urges the importance of clinical instruction in insanity, and of practical knowledge of that disease. His criticism that only trained and experienced physicians should be placed in charge of those suffering from mental diseases ought to be as superfluous as if the remark applied to lying-in hospitals. We second him most heartily in his recommendation of a moderate-sized hospital for the treatment of diseases of the mind, where every appliance which science can suggest or art can supply may be devoted to the cure of the insane. In our opinion, there is at the present time no greater need in our vast system of charities and noble endowments.

So far, at least, as our Massachusetts asylums are concerned, we have never sympathized with the howlers for office, the shriekers for notoriety, and the earnest and honest, but we think mistaken, friends of the insane, who have needlessly agitated the public mind with their ill-judged efforts to "reform" evils, the most of which exist only in imagination. We fully believe in the truth of a statement by the late Dr. S. G. Howe, that "all human institutions are of course liable to abuse, but our Massachusetts hospitals for lunatics are as well guarded against them as any public establishments with which I am familiar;" and again, "There are rather too many than too few difficulties in the way of committal" of patients to asylums in our State. We would gladly quote his whole letter but for want of space, and we would recommend its perusal (in the *Boston Daily Advertiser* of March 22, 1873) to those panic-stricken and Butler-fearing legislators of last year, who so recklessly threw the State Board of Health, Lunacy, and Charity tab to a still unsatisfied and unamused whale. We feel quite sure that few boards, commissions, or institutions, including the above-mentioned long-named board itself, could come out from a searching investigation

more unscathed and demonstrably altogether clean in all their operations than our lunatic hospitals have been lately proved to be. Nevertheless, we do see the need of improvement in certain directions, as do the superintendents themselves, and we fully appreciate the great difficulty of the work, as well as the obstacles (some of them unnecessary) which lie in their way. If Dr. von den Steinen's criticisms are received in the same friendly spirit with which they seem to be given, much good will result from his visit. We are fortunate in having for the medical superintendents of our insane hospitals men of the highest character, who fully deserve the sympathy and support of the community and of the medical profession. The trustees of the various institutions need only to be named in order to show on how vastly higher a plane than politics they stand. Political expediency had nothing to do with their appointment, and political ends have no part in their work. A generous support of the officers of the asylums, and a liberal policy towards the management of the insane on the part of the State, will be fully repaid by better results to the community and to a large class of suffering humanity, who are too often regarded as a useless mass of helpless poverty, or as a part of an interesting problem in social science.

We are glad to receive Dr. von den Steinen's criticisms, and consider them, in the main, of great value; but we must say that to compare the hospital for acute cases in Berlin, having every appliance and all the attendants necessary, with our asylums, crowded with the chronic insane, is hardly fair. If he had looked a little farther in his own country he would have found very much there also to criticise in the treatment of the chronic insane.

FIRST ANNUAL REPORT OF THE BOARD OF HEALTH OF THE TAXING DISTRICT OF SHELBY COUNTY (CITY OF MEMPHIS).

This first annual report of the Board of Health of what is euphemistically known in the language of the law as the Taxing District of Shelby County, but is really the city of Memphis, is for the year 1879. Information as to the steps which are being taken to improve the sanitary condition of Memphis is of more than local interest; it concerns the country at large, and this first report of the board of health will therefore command attention.

The president of the board, Dr. G. B. Thornton, frankly acknowledges that an appreciation of its sanitary deficiencies has not kept pace with the commercial growth and importance of the city; makes a deserved acknowledgment of the work done by the National Board in its behalf; expresses the conviction that the effort has not been made to little purpose, and that the part of the compact devolving upon the local authorities will be faithfully complied with.

Dr. F. W. Riley, an inspector of the National Board, under whose direction the house-to-house inspection of the city was made, and at the same time a census taken, places the average death-rate of Mem-

phis during three non-epidemic years at thirty-five, and states that of the total number of deaths during the past five years over fifteen per cent. was due to phthisis, pneumonia, and other diseases of the lungs, the excess being fairly attributable to defective sub-ventilation of dwellings and to an undrained, retentive soil; that excremental and malarial diseases caused nearly fifty-seven per cent. of the total; and that this excess may be set down as due, in great measure, to soil and water pollution. Dr. Thornton thinks that the population is underestimated by about five thousand, and the death-rate consequently over-rated. The temptations of local sanitary authorities, however, to reverse this error, and by magnifying the population to minimize the death-rate, is well known. Commercial rivalries, too, have their influence in swelling the estimated populations of cities, especially at the West. It is only fair to Memphis to call attention to the fact that the death-rate among the colored population, according to Dr. Thornton's estimate, is forty and a fraction over, while that of the whites is eighteen and a fraction over, which, as Dr. Thornton justly remarks, compares favorably with cities enjoying a better reputation than Memphis for health. Among the many nuisances abated and unsanitary conditions removed, the emptying, disinfecting, and filling up of privy vaults and destruction of unsanitary houses bear an important part. A garbage service under the immediate charge of the health officer has been established; this is the first attempt at a garbage system Memphis has ever had. There are at present about a dozen private scavenger companies engaged in the removal of night soil; these companies are all required to use air-tight barrels, and are subject to the regulations of the board of health.

The report discusses the question of a wholesome water supply, and also the sanitary arrangements of the public schools, which are far from satisfactory. Attention is called to the necessity for the construction of a general abattoir, and the erection of public latrines is suggested. The report concludes with a summary of the yellow-fever epidemic for 1879, and an account of the Auxiliary Sanitary Association. This part of the report is not altogether uninteresting as showing some of the evils of a multiplicity of sanitary organizations. In a multitude of sanitary com-mittees there is not usually safety.

Memphis has now taken the best advice for improving her condition which she could get, and her authorities seem anxious, as far as the means at their disposal will permit, to act upon it, and that the rest of the country had a right to demand. The provincial customs of a village existence cannot be exchanged for the arrangements suitable to a good-sized city in a year.

A beginning has been made which could serve as an example to places not far away; for if they have any occasion to thank themselves that they are not as other cities are, it is to be found rather in the absence of a large and ignorant negro population and of a semi-tropical climate during six months of the year than in their own hygienic virtues.

MEDICAL NOTES.

— At a meeting of the State Board of Health, Lunacy, and Charity, held May 1st, an order was passed requiring the city of Boston to abate the Roxbury Canal nuisance by dredging out the sewage deposits in its basin. The Pegan Brook case has not yet been finally passed upon.

Dr. George F. Jelly and the secretary of the board were appointed as experts to examine convicts at the state prisons reported to be insane and fit subjects for treatment in a lunatic hospital, as required by the following provision in section five of a recent act of the Massachusetts Legislature concerning the commitment and transfer of lunatics: Sect. 5. The State Board of Health, Lunacy, and Charity shall designate two persons, expert in cases of insanity, to examine convicts in the state prison or reformatory prison for women alleged to be insane. When any such convict appears to be insane, the warden or superintendent of the prison shall notify one of the persons designated by said board, as aforesaid, who shall, with the physician of such prison, examine the convict, and report to the governor the results of their investigations. If upon such report the governor shall deem the convict to be insane, and that his removal is expedient, he shall issue his warrant, directed to the warden or superintendent, authorizing him to cause the convict to be removed to one of the state lunatic hospitals, there to be kept until in the judgment of the superintendent and trustees of the hospital to which he may be committed the convict should be returned to prison.

— We have received the thirteenth annual report of the St. John's Hospital Staff, of Lowell, Mass. The institution is in a flourishing condition. A strong appeal is made by Dr. Nathan Allen in favor of the institution of Hospital Sunday.

— We regret to be obliged to announce the recent deaths of two well known Boston practitioners, both, we are informed, from pneumonia, Dr. A. B. Hall, and Dr. John P. Ordway. Dr. Hall was a graduate of Dartmouth, of 1845. The following year he joined the Massachusetts Medical Society, and has resided in this city. For many years he has filled the post of treasurer of the Suffolk District Medical Society, and in that capacity has come in contact with practitioners from all parts of the State at the annual meetings. He will be pleasantly remembered by them for his uniformly courteous bearing, and by the District Society for the efficient and faithful discharge of his duties.

Dr. Ordway did not begin the study of medicine until comparatively late in life. He graduated at the Harvard Medical School in 1861. A man of versatile accomplishments, a musician and sportsman as well as an active practitioner, he was a well known character in the city. His enterprise and genial nature obtained for him a host of friends. He devoted himself chiefly to the treatment of fistula in ano, in which he claimed great success with the ligature. Some years since he received a severe railroad injury, having been thrown from his seat in the cars, sustaining a blow

which produced ventral hernia. This interfered, however, in no way with his activity, which was undiminished at the time of his death. During the war he served in the army in a medical capacity.

— We are very sorry to receive intelligence of the death, from pneumonia, of Dr. Samuel Choppin, of New Orleans. Dr. Choppin's active professional labors and great services in behalf of sanitary science have been such that his loss will be felt in the country at large as well as in that part of it where his life has been spent.

— It is related of an eminent painter, Vernet, says the *Lancet*, that on one occasion, being asked to produce a pencil sketch, he did so while the applicant waited. When the latter protested against the price charged the painter replied, "Do you think I spent but ten minutes in drawing that sketch? It represents the labor of thirty years." The anecdote should be useful to patients who criticise the just charges of their physician.

— Dr. F. E. Clarke, of Staten Island, reports in the *Medical Record* a case of scarlet fever in which the period of incubation was exactly determined, and was a remarkably short one. The patient, a robust young man, called, on the night of February 10th, on some relatives who had lost a child from scarlatina maligna seven days before. He did not know of this death until the evening of his call. He stayed with the family for several hours. On the following evening his throat became sore, and he did not feel very well. At this time he ate heartily of soft-shelled clams. The next forenoon, about thirty-six hours after leaving the infected house, he was taken with violent vomiting, slight diarrhoea, headache, and sore throat. The next morning, two and a half days after exposure, the rash was first seen. By the same night it was fully developed. The patient went through the usual course of scarlet fever. At the end of a week he was convalescent, and his recovery was rapid and satisfactory.

Dr. Clarke states that this was the shortest stage of incubation he had ever seen, and only knew of three others that were shorter. Two of these were reported by Marchison, the incubation being in one eighteen and the other twenty-four hours. Trousseau reports a case where the incubation was only seven or eight hours.

— According to the *Medico-Chirurgicale Rundschau*, Admiral Lapellin draws attention to a bean which is used by the inhabitants of Central America in the treatment of the cold fever, and which is said to be a good substitute for quinine. Dr. Coignard, who obtained the remedy in Puerto Arenas, Costa Rica, obtained favorable results with it, and Drs. St. Père and Quesnel found it even more powerful than sulphate of quinine. The bean is cut into bits as large as a pea, several of which are given in the interval between the paroxysms. This almond or bean is obtained from the *Simaruba ferruginea*.

— In the treatment of neuroses of the genito-urinary organs, Dr. Uitzmann, of Vienna, teaches that electricity plays an important part. Faradization of the bulbo-cavernosus and ischio-cavernosus muscles is

a useful procedure in impotence. One of the electrodes should be used in the rectum, the other applied externally.

PROVIDENCE.

— The *JOURNAL* has already published an account of the sudden death of a patient while under the influence of ether, which occurred in this city in December last. The relatives of the deceased have brought a suit for damages against the attending surgeon. In view of this action the Rhode Island Medical Society at a recent meeting unanimously adopted the following resolutions:—

Whereas, We have heard with much surprise and indignation that a most unjustifiable suit has been entered against a physician, a Fellow of this society, for an unavoidable accident, which occurred in the administration of ether, rendered necessary by the nature of the injury from which the patient was suffering, whereas the facts in the case as testified to before a coroner's jury prove that no blame attaches to the physicians in attendance on the case, and whereas a similar accident may happen to any member of the profession in handling their cases, when the administration of an anæsthetic is absolutely demanded for the relief of their patients, or otherwise patients must be abandoned to their fate.

Resolved, That we, as a society, knowing the difficulties that we encounter in our practice, deprecate a proceeding which, if sanctioned, would expose us to annoyances and persecution; that we deprecate it on behalf of the poor, who are exposed to severe accidents, and to whom our services, so often rendered gratuitously in their sudden and sharp affliction, would be denied if we are in peril of being persecuted by law suits as a reward for the exercise of charity and for carrying out the humane spirit of our profession.

— A singular case has recently come under the observation of Dr. F. B. Smith, of the town of Coventry in this State. The patient, a lad of fourteen years, has become possessed of an inordinate appetite, which leads him to devour with avidity all that he can obtain in the way of food, even raw meat being eaten with apparent relish. During the past year his weight has increased at the rate of half a pound per day, and has now reached two hundred and eighty-four pounds. The intervals between his meals are spent principally in sleeping. He appears to be in good health in other respects, and complains of nothing except hunger. The further progress of the case will be watched with interest.

NEW YORK.

— An unusually large and interesting meeting of the American Medical Association is expected this year, and the New York committee of arrangements, under the energetic chairmanship of Professor T. Gaillard Thomas, are now busily engaged in making such provisions as will insure a successful and enjoyable session. Among the entertainments contemplated are a grand reception at the Academy of Music on the first evening of the meeting, receptions at Mayor Cooper's and at the Academy of Medicine on subsequent even-

ings, and a steamboat excursion up the Hudson and down to Coney Island, which is to take place immediately on the final adjournment of the association, and the expense of which will be borne by Mr. William Wood, the publisher. The committee of arrangements consists of Dr. Thomas, chairman. Dr. Walter R. Gillette, secretary, Drs. Stephen Smith, C. I. Pardee, W. M. Polk, R. F. Weir, A. A. Smith, and M. A. Allen, of New York, Dr. Joseph C. Hutchinson, of Brooklyn, Dr. M. A. Burton, of Troy, and Dr. E. H. Parper, of Poughkeepsie. There is also an associate committee, consisting of Drs. C. A. Leale, Le Grand N. Denslow, L. A. Rodenstein, P. Brynberg Porter, Charles W. Packard, Daniel Lewis, and others.

—The dreadful calamity at the Madison Square Garden, where the fair in aid of the homoeopathic hospital was being held, is naturally exciting a great deal of public interest, and it is hoped that the inquiry concerning it, which is now in progress, and the investigations made in connection with it, will have the effect of rendering the occurrence of such a needless catastrophe henceforth impossible in this city. As far as can be made out at present, there seems to be no doubt that the owners of the property and the Department of Buildings are directly responsible for this wanton destruction of human life: the former being culpable for constructing such a wretchedly insecure edifice, and the latter for allowing its erection. For a considerable time past it has been believed by those who had the best opportunities for information on the subject that there has been not only the most reckless negligence, but even gross corruption, on the part of the principal officers of this department of the city government (an opinion which this disaster would seem to go very far towards confirming); but hitherto political trickery has interfered with an exposure and removal of the existing evils. Efforts have not been wanting from time to time, however, to put an end to such a disgraceful state of affairs, and since the Madison Square calamity some resolutions were introduced into the board of aldermen by one of its most efficient and public-spirited members to the effect that a committee should be appointed for the purpose of bearing testimony and collecting all facts, statements, and other matter bearing on the subject. The preamble of these resolutions is as follows: "*Whereas*, The late dreadful calamity at Madison Square Garden, by which several persons have lost their lives, and many others have been mutilated and injured, has filled this community with horror and just indignation; and, *Whereas*, this disaster has again directed public attention to the administration of the Department of Buildings, in regard to the proper conduct of which frequent allegations have been made,—which allegations have as yet received no thorough official investigation or inquiry; and, *Whereas*, This occurrence, coupled with the facts and statements previously averred, which have never been satisfactorily explained, furnishes strong ground for belief that the administration of the Department of Buildings is such as to shake public confidence in its efficiency and honesty, and to cause it to be regarded,

not as a protection to the lives and property of the community, but as an agency which is placing these in peril."

WASHINGTON.

—The following, as a joint resolution, passed the United States senate on April 29th: *Resolved, etc.*, That the president of the United States is hereby authorized to call an international sanitary conference to meet at Washington, District of Columbia, to which the several powers having jurisdiction of ports likely to be infected with yellow fever shall be invited to send delegates, properly authorized, for the purpose of securing an international system of notification as to the actual sanitary condition of ports and places under the jurisdiction of such powers and of vessels sailing therefrom.

A resolution in the form of an amendment to this was offered, appropriating \$5000 to defray the necessary expenses, but it was voted down.

—As an evidence of the sometimes disastrous effect of tardy legislative action on the "save at the spigot, lose at the bung," principle, that part of the discussion on the Indian appropriation bill which refers to the supply of medicines and medical services is very forcible. The Northern Cheyennes, some five thousand in number, were placed upon a government reservation, comprising a radius of fifteen to thirty miles, which was infested with malaria, a condition of things hitherto unknown to these Indians, who had come from a region entirely free from it. To meet their wants they were supplied with *one* attending physician (recently he has been furnished with an assistant). Hundreds of these Indians fell sick; a requisition for medical supplies was made upon the department in May. June 19th the contract was awarded; August 27th the contract was approved; November 28th the medicines were delivered; January 17th these supplies were received at the post for which they were intended. What an encouragement for medical men who seek such places! — a family of five thousand under the exclusive care of one man, with miles of territory between him and his patients, the probabilities that all will suffer more or less from a disease which they have never before encountered, and no medicine.

But then they have a fair appropriation for industrial schools; moral pocket handkerchiefs are not set down as such in the bill.

Miscellany.

CRUDE PETROLEUM IN ASTHMA.

MR. EDITOR, — It is a well-known fact that many of our most valuable medicines have been borrowed or developed from general impressions or the prevailing prejudice of the common people in some district or country. Jenner deduced an important scientific truth from the vague notions and common prejudice of the dairymen of Gloucestershire. In like manner it has been with many of the important remedies of the now extensive materia medica, which have often been in use by the common people before being investigated by the profession.

Pursuing this line of observation, we find the veterinary surgeons, farmers, and horse-jockeys now pre-

scribing the ordinary crude petroleum as a remedy for broken wind and heaves in horses, and with astonishing success, improving the general condition of the animal, giving him a fine appearance, and removing the difficulty of breathing as if by magic: a cure which they are willing to swear is permanent, which assertion I accept with several grains of allowance. Heaves and broken wind I have always looked upon as due to emphysema, and consequently treatment must necessarily be only palliative. Crude petroleum is a stimulating anti-spasmodic expectorant and diaphoretic of no mean power. It seems to act by stimulating the secretions generally, especially those of the skin, and improving the digestive functions. The dose for the horse is one teaspoonful in meal, placed well back upon the tongue, two or three times per day, continued until relief is afforded.

Having seen the beneficial effects of this remedy frequently applied to the horse, I was led to experiment on that difficult disease to cure, asthma. I used the ordinary oil in various combinations, as in syrups, emulsions, etc.; but however it might be combined, I found that it always produced a disagreeable cruetation, and that it was hard to induce patients to persevere in its continuance. But the semi-solid oil that accumulates on the tubing and casings of the wells, and hardens to the consistency of putty, made into pills of five grains by incorporating with some inert vegetable powder, and taken every three or four hours, has afforded almost instant relief. The paroxysms will not return under its usage. It is not curative, but the patient does not suffer while taking the pills, and after a few days the spasmodic symptoms seem to pass off. Many asthmatics cure affected only in the spring or fall, and after these attacks pass off they are comparatively comfortable. Nothing has afforded me as much relief in the treatment as these pills in hay fever, autumnal catarrh, or asthmatic bronchitis. The cough and dyspnea are promptly alleviated.

I have already called the attention of the profession to the value of this remedy in pulmonary tuberculosis.

M. M. GRIFFITH, M. D.

IRVING, N. Y.

LETTER FROM ST. LOUIS.

THE ST. LOUIS MEDICAL SOCIETY; A CASE OF DOUBTFUL GENDER; THE SANITARY COUNCIL.

MR. EDITOR,—At the meeting of the St. Louis Medical Society, held April 10th, Dr. S. T. Newman reported that in combining calcined magnesia and hydrate of chloral in a prescription, chloroform had been formed after the solution had stood for some hours, and the effect of the medicine was the same as if chloroform had been given internally. At first he supposed a mistake had been made, but experiments proved that the combination of magnesia and chloral produce chloroform.

Dr. Fairbrother, at the same meeting, reported a case of disfigurement by gunpowder, the treatment of which showed considerable ingenuity. Some time previously the patient had his face blackened and burned by the explosion of a gun which he was attempting to fire. When he presented himself for treatment, his face being very much discolored, he was anxious to have the discoloration removed. The doctor saw that it was impracticable to accomplish this by any *vis a fronte*, and devised the following method for producing

a *vis a tergo*. He painted the face (small portions at a time) with cantharidal collodion, producing vesication, and then applied poultices. The discoloration in the epidermis of course disappeared so soon as the epidermis was removed by the blistering, and the discoloration located in the rete mucosum and corium was washed out by the serum in its exudation into the blisters. The result was very gratifying; the face regaining its normal color except in the angle between the nose and the cheek, where the vesication was not done as carefully as in the other situations.

Dr. E. H. Gregory invited the members to examine a case of doubtful gender, which had presented itself to him to know if marriage were possible. The face, figure, and general appearance of the patient were those of a man. It wore a beard, and was rather above the average size. Upon examining the genitals there was found an organ resembling a penis, from two and a half to three inches in length, in a flaccid condition, and a little larger than a man's thumb in circumference, bent upon itself as if in a chronic condition of chordae. The glans was disproportionately small, being about the size of the last phalanx of a man's little finger. The covering of the corpora cavernosa was perfect integument. Upon raising this organ perfect labia majora and minora and a vagina about three inches in depth and rather small in circumference were revealed. The urethra did not extend to the end of the organ resembling a penis, but opened into the vagina, the meatus being farther back than it is in women, the urethra being continued on the under surface of the penis as a deep groove. The labia minora on the under surface of the glans seemed to replace the *frænum preputii*; farther back they extended up over the corpora cavernosa, and as we have already said in this position they had all the appearance of true skin. These attachments of the labia gave the peculiar curvature to the organ.

With a catheter in the bladder and a finger in the rectum no uterus could be discovered. There were no testicles in the labia majora. The patient is nineteen years old; has orgasm accompanied by some sort of ejaculation; has never attempted connection with a woman, but the passion is directed toward women. The patient came to have the urethra extended to the end of the penis or clitoris, which ever it may be, as the statement had been made that if this were accomplished he or she would be able to beget children. There is no menstruation, and no ovaries have been found. Dr. Gregory will probably discourage any idea of marriage.

The Sanitary Council of the Mississippi Valley has just held its meeting in St. Louis. Dr. J. D. Plunket, president of the State Board of Health of Tennessee, presided, and Dr. John H. Ranch, of the Illinois State Board of Health, acted as secretary. Among those present were Dr. H. A. Johnson, of Chicago, member of the National Board of Health; Dr. Thompson, delegate of the Kentucky State Board of Health; Dr. Lindsley, representing the Tennessee Board of Health; Dr. Lyman, of the New Orleans Auxiliary Sanitary Association; and Dr. Geo. Homan, from the St. Louis Board of Health.

Reports from several committees were received, showing that the members of the council have been attending to their duties since the council's organization, not quite a year ago. They also adopted the following resolutions:—

Resolved, That the passage of the bill now before

Congress, to increase the efficiency of the National Board of Health and to provide the funds necessary to enable it to aid financially state and local boards of health, is in all its essential features wise and judicious.

Resolved, That the senators and representatives in Congress, from the States represented by this council, are respectfully requested to support in all important particulars this measure.

The usual tours of inspection were made, and on one of them the following resolution, very gratifying to St. Louis, referring to our quarantine station, was adopted, it being introduced by Dr. Lindley, of Tennessee:—

Resolved, That the council have viewed with special interest the provision made at the quarantine station for the care of those having infectious or contagious diseases. From a strictly sanitary stand-point, and for the general purposes for which it is intended, it is superior to anything in the valley of the Mississippi.

The officers for the ensuing year are Dr. R. C. Kedzie, president, president of the Michigan State Board of Health, and Dr. Pinckney Thompson, vice-president, president of the Kentucky State Board of Health. Dr. John H. Rauch tendered his resignation as secretary, but the council declined to accept it.

Dr. Plunket, who was famous for his Order No. 6,

last summer, and was hanged and burned in effigy in Memphis, when asked if there was likely to be an epidemic of yellow fever this year, replied that there might be a few scattering cases through the Mississippi Valley; but he did not anticipate another epidemic.

X.

COLOR BLINDNESS.

MESSRS. EDITORS.—In the journal of the British Medical Association it has been proposed, as a test question, to examine for color-blindness all the members present at the annual meeting at Cambridge, August 3d to 5th.

It would be a valuable contribution to science to be able to do the same in reference to the Massachusetts Medical Society at our coming meeting. This I hope to undertake if the members are willing to spend the time, not over one minute, for the test. The value of the investigation would, of course, largely depend on having all the members recorded. Names would neither be used or published, thus it would not be known who proved to be defective in the chromatic sense. May I ask for the coöperation of the JOURNAL in this investigation? Respectfully yours.

B. JOY JEFFRIES, M. D.

15 Chestnut Street, Beacon Hill, May 3d.

REPORTED MORTALITY FOR THE WEEK ENDING APRIL 24, 1880.

Seventeen Massachusetts towns.	134,910	38	7	7.89	15.79	2.63	5.26	—

Two thousand four hundred and thirty-three deaths were reported; 933 under five years of age; principal "zymotic" diseases (small-pox, measles, diphtheria and croup, diarrhoeal diseases, whooping-cough, erysipelas, and fevers) 342, lung diseases 404, consumption 372, diphtheria and croup 102, scarlet fever 50, measles 48, typhoid fever 38, diarrhoeal diseases 31, whooping-cough 20, malarial fevers 19, erysipelas 16, cerebro-spinal meningitis 15, small-pox three. From *measles*, New York 15, Brooklyn 10, Philadelphia eight, Chicago, St. Louis, and Pittsburgh four, Holyoke two, Cincinnati one. From *whooping-cough*, Pittsburgh four, Brooklyn and Cincinnati three, New York, Philadelphia, Baltimore, and Nashville two, St. Louis and Worcester one. From *malarial fevers*, Brooklyn eight, New York six, St. Louis four, Baltimore one. From *erysipelas*, New York six, Chicago three, Philadelphia and Brooklyn two, Baltimore, Cincinnati, and Milwaukee one. From *cerebro-spinal meningitis*, New York four, Philadelphia, Milwaukee, and Fitchburg two, District of Columbia, Pittsburgh, New Haven, Worcester, and Taunton one. From *small-pox*, Philadelphia, Chicago, and Worcester one.

One hundred and nine cases of measles, 41 of diphtheria, 28 of scarlet fever, three of whooping-cough, and one of typhoid fever were reported in Brooklyn; diphtheria 24, scarlet fever six, in Boston; diphtheria 23, scarlet fever five, in Milwaukee; scarlet fever 24, diphtheria seven, cerebro-spinal meningitis four, erysipelas two, typhoid fever two, measles one, in Providence; diphtheria four, scarlet fever one, typhoid fever one, in Cambridge; scarlet fever five, diphtheria four, in New Bedford.

The total number of deaths reported was considerably diminished from that for the previous week, and the deaths under five diminished in about the same proportion. Lung diseases and pulmonary consumption diminished. Principal "zymotic" diseases diminished twenty-five per cent. Typhoid fever diminishing in Pittsburgh. One death from small-pox in Philadelphia, in Chicago, and in Worcester. In 36 cities and towns of Massachusetts, with an estimated population of 1,023,560 (population of the State about 1,690,000), the total death-rate was 19.82 against 22.66 and 22.89 of the previous two weeks.

For the week ending April 3d, in 150 German cities and towns, with an estimated population of 7,13,077, the death-rate was 28.6 against 28.9 and 27.6 for the two previous weeks. Five thousand six hundred and ninety-nine deaths were reported; 1976 under five; pulmonary consumption 677, acute diseases of the respiratory organs 597, diphtheria and croup 162, whooping-cough 63, typhoid fever 60, scarlet fever 59, measles and *rubella* 50, puerperal fever 24, typhus fever (Braunschweig, Königsberg, Thorn, Beuthen) five, small-pox (Königsberg, Beuthen) four. The death-rates ranged from 18 in Potsdam to 38.6 in Aachen; Königsberg 37.8; Breslau 33.7; München 36.9; Dresden 26.5; Berlin 25.7; Leipzig 28.6; Hamburg 28.6; Hannover 21.4; Bremen 24.8; Cologne 28.3; Frankfurt 26.4; Strassburg 27.7. For the same week, Vienna 35.3, small-pox greatly diminished, scarlet fever one death; Paris 29.8, small-pox, diphtheria, and typhoid fever prevalent.

The meteorological record for the week in Boston was as follows:—

Date.	Barom-eter.		Thermom-eter.		Relative Humidity.				Direction of Wind.			Velocity of Wind.			State of Weather. ¹			Rainfall.

DR. HENRY JOHNSON.

At a meeting of the New Bedford Society for Medical Improvement, held on April 21st, the following preamble and resolutions were passed:—

Whereas, Death has removed from our midst our muchesteemed friend and colleague, Dr. Henry Johnson, of this city, and *whereas*, it is fitting that this society, of which he was one of the founders, and at the time of his decease its vice-president, should express their feeling of sorrow at this great loss, therefore

Resolved, That we gladly testify to our appreciation of his great professional skill, his readiness to advise whenever called upon by any of us, his honesty of principle toward his medical brethren and toward his patients, his affability at our social gatherings, all of which we shall always hold in grateful remembrance.

Resolved, That the death of Dr. Henry Johnson is a loss to the community in which he lived and worked so many years, but that this loss will be felt more directly by his professional associates.

Resolved, That as a token of respect for his memory this society attend his funeral in a body.

Resolved, That a copy of these resolutions be spread upon the records of this society, a copy forwarded to his afflicted family, a copy published in the local papers and in the Boston Medical and Surgical Journal.

W. H. TAYLOR, M. D., Secretary.

Messrs. W. H. THOMPSON & Co., 32 Hawley Street, Boston, are the New England agents for Reynolds's System of Medicine, noticed in our last number.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U. S. ARMY, FROM APRIL 24, 1880, TO APRIL 30, 1880.

MOORE, JOHN, major and surgeon. Granted an extension of two months of his present leave of absence. S. O. 90, A. G. O., April 23, 1880.

ATSWORTH, F. C., captain and assistant surgeon. The operation of so much of paragraph 1, S. O. 74, C. S. A. G. O., as relates to him is suspended until September 1, 1880. S. O. 83, A. G. O., April 22, 1880.

SEFFOLK DISTRICT MEDICAL SOCIETY. — A regular meeting will be held at the hall, No. 19 Boylston Place, on Saturday evening, May 8th, at seven and a half o'clock. The following papers will be read: Dr. Douglas Graham, *Massage in the Treatment of Uterine Affections*, with a Report of Seventy-Two Cases; a reply in part to the paper of Dr. Wing on the Modern Abuse of Gynecology. Disputants, Dr. James R. Chadwick, Dr. William H. Baker. Dr. J. B. Swift, *A Case of Empyema illustrating the Value of the Antiseptic Operation*. All members of the Massachusetts Medical Society are cordially invited to be present, and to take part in the discussion.

H. C. HAYES, M. D., Secretary.

We have received the first four volumes of Wood's Library of Standard Medical Authors for 1880, which indicates success on the part of the publishers in their "endeavor to supply standard professional literature at a price lower than ever before attempted in any country."

Lectures.

ON THE DIAGNOSIS OF OVARIAN TUMOR.¹

A LECTURE DELIVERED AT RUSH MEDICAL COLLEGE,
CHICAGO, FEBRUARY 9, 1890.

BY PROFESSOR W. H. BYFORD, M. D..

GENTLEMEN, — We will consider to-day the subject of the ovarian tumor. An ovarian tumor, when small, may be mistaken for extra-uterine pregnancy, tumor of the Fallopian tubes, fibroid tumor of the uterus, and pregnancy. These are, perhaps, the most common disorders of the pelvic viscera which are liable to be confounded with ovarian dropsy, but further along enlargement of the spleen, peritoneal dropsy, enlargement of the liver, kidneys, and bladder, may also be mistaken for ovarian tumor.

Let us now look at some of the symptoms, both objective and subjective, which these disorders present, and compare them with those found in dropsy of the ovary, and see if we shall be able to make a correct differential diagnosis in most cases. In pregnancy the symptoms and signs pertaining to that condition will be present, including more obtained by auscultation and palpation, and the tumor is found in the centre of the pelvis, and is symmetrical in shape. Where we have an ovarian tumor the symptoms of pregnancy are absent, and we will find the uterus crowded forward nearer the abdominal wall, and the tumor will be found in the cul-de-sac of Douglas. How may we know when we have a tumor of the Fallopian tubes? We shall find this variety of tumor located at or near the side of the uterus, and oblong in shape, while an ovarian tumor is globular, and situated behind the uterus. We may be pretty sure that we have a fibrous uterine tumor when we find that the mouth of the uterus is hard and misplaced; that there is menorrhagia or metrorrhagia; that the tumor itself is hard; that when the uterus is moved the tumor moves also, and the cavity of the uterus is enlarged.

We shall probably experience great difficulty in diagnosing an extra-uterine pregnancy, or rather in differentiating it from ovarian dropsy. In extra-uterine pregnancy the tumor is generally in the posterior cul-de-sac, is globular, pushes the uterus forward, and extends up into the abdominal cavity like an ovarian tumor. So far, you see how these two growths may simulate each other and deceive the physician unless he is extremely careful. But there are some other symptoms and characteristics about extra-uterine pregnancy which will enable us to tell the difference between it and ovarian tumor.

In extra-uterine pregnancy we shall have the usual symptoms of pregnancy; gastric disturbance, nausea, enlarged breasts, and the nervous phenomena accompanying a case of pregnant uterus, attended with irregular hemorrhages and the discharge of organized material or membrane.

When the abdomen is large, ovarian tumor may be mistaken for abdominal dropsy, and *vice versa*. In ovarian tumor the patient is often in comparatively good health, while in abdominal dropsy there is generally some serious constitutional trouble. The liver, heart, or kidneys are usually affected. In peritoneal dropsy there is generally oedema of the feet or genital organs, or both, while in cases of ovarian tumor the

patient may go almost to the last stages of the disease without any oedema, and then if any be present it may be caused by anæmia.

For examination, first place the patient on her back, and in ovarian dropsy there will be seen to be some irregularity of contour, while in peritoneal dropsy there is no irregularity. Percussion in ovarian tumor reveals dullness all over, except at the sides near the spine and high in the epigastrium, where you get in testinal resonance.

In peritoneal dropsy there is sometimes very marked resonance over the middle of the abdomen. In dropsy there is fluctuation everywhere, while in ovarian tumor the fluctuation ceases when we get beyond the border of the tumor. Now have your patient sit up, and, if peritoneal dropsy is present, the belly will sag and the tumor will decrease in size above, with increased resonance above, while the abdomen will enlarge below, with dullness in front. In ovarian tumor there will be no change in the shape of the abdomen or the location of the intestinal resonance.

Sometimes abdominal dropsy and ovarian tumor co-exist in the same patient. In a complication like this we need to use unusual care and tact in making a diagnosis.

There will not be resonance in front, because the intestines do not rise up to the abdominal wall. Place the patient on her back, and push the ends of the fingers into the abdominal wall, and press them together from either side. If you can engage a tumor between your hands you probably have something besides abdominal dropsy. The aspirator or trocar will aid us in the diagnosis, as we shall find after a while. An important point in the diagnosis of these ovarian growths is to determine whether they are monocystic or polycystic. The monocyst is generally globular, and fills the abdomen symmetrically, and does not present any very marked prominences or depressions. There is no difference in the wave of fluctuation, no matter at what point you percuss. But in a polycyst the fluctuation is not the same in different localities of the abdomen. You can map out pretty definitely the different cysts which compose the growth.

Sometimes a deposit of fat in the abdominal walls will mislead us, and we may suppose we have an extra-peritoneal growth. Fat is found in the walls of the abdomen from half an inch to ten inches thick. This layer of adipose tissue is outside of the abdominal muscles, between them and the skin. If you place the patient on her back and make percussion, you will get a wave of fluctuation which is similar to that of serum; you will be deceived by it unless you are careful. Now place one hand one side of the abdomen and tap upon the other side and you will feel the whole mass tremble; and although the sensation is similar to that of the fluctuation you get from a sac filled with serum you can detect the difference if in percussing you place the fingers far down on either side opposite each other. If the enlargement is due to fat you can grasp the mass and lift it up in rolls from the abdominal muscles. I have known two instances where patients have been tapped and no fluid was drawn, because the trocar or aspirator was plunged into a mass of fat, which fortunately the instrument did not pass through. I have said that an enlargement of the bladder may simulate ovarian tumor. I have seen the bladder so distended as to reach within three inches of the ensiform cartilage.

¹ Reported for the JOURNAL by B. W. Griffin, M. D.

The history of a case of distended bladder is as follows: The patient is troubled with apparent incontinence of urine, swelling goes on for several months, urine dribbles away all of the time in very small quantities. On introducing the catheter you draw off an enormous quantity of urine, and the tumor disappears. Do not tap a distended bladder, thinking you may have an ovarian tumor. Always empty the bladder before tapping for any purpose. The stomach can be so distended as to fill up the entire abdominal cavity.

I know of a case in which an attempt was made to take out the stomach by surgical means, under the impression that it was an ovarian tumor. On introducing the trocar, after the incision was made, to draw off the fluid which the supposed ovarian tumor contained, a part of the patient's breakfast was brought into view, and it was at once decided that the growth was not ovarian dropsy. Succession and percussion in these cases would do much to reveal the presence of fluid mixed with gas. I should think that there would always be grave gastric disturbances in all such cases. There is sometimes enlargement of the spleen, which presents some similarity to ovarian tumor. In such cases you will find a hard tumor, which sometimes extends from top to bottom of the abdominal cavity.

But in the enlargement of the spleen there is not much elevation of the abdominal walls. The tumor is thick above and thin below. The crucial test is percussion. By forcible percussion you get decided resonance and no fluctuation in hypertrophy of the spleen, while in ovarian dropsy dullness and fluctuation are prominent features. The spleen extends up into the region of the left lung, and the dullness of that organ is increased. Another diagnostic mark of great value is that the tumor is also attached to the left side, and does not descend within reach of the fingers per vaginam. The liver, when enlarged and displaced, sometimes drops down to the brim of the pelvis. These migrating livers may deceive us. As in case of enlargement of the spleen, the tumor is comparatively flat. In percussing, if you commence upon the lung, and follow down to the intestines, you fail to find the usual space of hepatic dullness under the ribs. There is no line of dullness between the resonance of the lungs and intestines; the pulmonary resonance is immediately succeeded by that of the intestines. The liver can sometimes be replaced by pressing it carefully upward, but it will not remain so.

Cystic enlargement of the kidney may also be mistaken for ovarian tumor. This little organ, which is so insignificant in health, so far as size is concerned, often becomes large enough to fill the abdominal cavity from the diaphragm to the pubes. The tumor thus formed is nearly globular, and slightly elongated from above downward. Fluctuation is sometimes well defined. Where the kidney attains to this enormous size, the disease is generally of a malignant character, and the health is broken down. This is not the case in ovarian tumor.

About a year ago I removed a diseased kidney which had attained the weight of fifteen pounds. The patient is now in good health. If the right kidney is enlarged there will be more fullness on that side and a dull sound on percussion, while on the left side there will be resonance. In enlargement of the liver or kidney the tumor does not descend into the pelvis.

Besides the varieties I have mentioned as resembling in different ways an ovarian tumor, there are tu-

mors of the omentum which simulate ovarian tumor. The omentum lies over the intestines like an apron. When a sarcomatous or carcinomatous deposit takes place in the omentum, it is thickened, and presents an irregular surface. It does not elevate the abdominal walls, like an ovarian tumor. By placing the patient on her back and employing deep pressure with percussion, we can elicit a good degree of resonance over a large part of the tumor.

Inflammatory depositions in the abdomen, resulting from local or general peritonitis, in puerperal cases especially, but sometimes not connected with the post-partum condition, are sometimes mistaken for tumors.

In puerperal peritonitis a deposition of fibrin glues the intestines together, and leaves them in this condition for months. The hard masses thus formed feel like tumors, and sometimes extend into the pelvis. They do not render the abdomen so prominent as the ovarian tumor, are firm, and do not fluctuate. They are almost always tender; there is generally greatly impaired health, and they date back to a sharp febrile attack, as before remarked, most frequently of a puerperal character. Percussion elicits loud resonance over almost the whole of the hardened surface.

Small hardened loculi are often found in the iliac region, and even elsewhere near the pelvis, that may perplex the young practitioner. They are immovable, not generally globular, date from an inflammatory attack, and disappear after appropriate counter-irritant and sorbificient treatment.

I come now to speak of the differential diagnosis between ovarian and fibro-cystic tumors of the uterus, which is probably more perplexing to the surgeon than any heretofore mentioned. The external appearances resemble almost exactly, in many instances, an ovarian tumor. There are generally, however, to the practiced eye and skillful touch marks of difference which will, to some extent, serve in differentiating between them. One diagnostic mark is that there are often sulci somewhere between the sacs which compose the growth as a whole. The reason for this is that the walls are thick and not sufficiently elastic to allow them to round out and form a smooth and globular tumor like that of the tumor of the ovary. We may also occasionally observe nodules projecting from their surface, and when closely examined the fluctuation may be found to be less extensive and obvious than in ovarian tumors.

I have said several times in the course of my lectures that tapping by the trocar or aspirator is a very valuable means of demonstrating the character of abdominal tumors. It is now thought that there is very little difference between the trocar and the aspirator so far as danger from their use is concerned. Probably as many deaths result from tapping with the aspirator as with the trocar. Remember, gentlemen, that there is more or less danger in using either of these instruments. I have seen only one death happen in about eighty cases which I have tapped. This is an unusually favorable experience, however, as statistics go to show that about one in fifty cases dies from tapping. There are some things in favor of the use of the trocar.

The patient is relieved more quickly than with the aspirator, and the fatigue which is a result of the use of the aspirator is largely done away with. You can also get a better idea of the character of the fluid drawn by the use of the trocar than by the aspirator.

When you plunge a trocar into a monocystic or oligocystic tumor, the fluid, being there, generally runs away rapidly. You will notice that in these varieties of tumors there is a foam or bead on the surface of the fluid, especially if it is drawn away rapidly. In tapping either variety just mentioned you will see that the abdomen decreases in size equally in all directions. But, on the contrary, in peritoneal dropsy the enlargement decreases first from above. The fluid from peritoneal dropsy is lighter than that from a monocyst, but is not viscid.

After you have drawn off the fluid which has accumulated in the peritoneal space, you can by palpation and careful manipulation map out pretty plainly the abdominal viscera. But this cannot be so well done in case of ovarian tumor. The walls of the tumor may sometimes be grasped by the hands, while in dropsy, after tapping, we can find nothing of the kind. The fluid from the cyst feels viscid between the fingers, although it may be thin. In tapping a polycyst we very often get a dark-colored, viscid fluid, which runs in a stream like a string, and does not fall and produce a splashing sound like a thin fluid. Its viscosity, too, is more marked than in monocystic fluid. Where we have a polycyst and tap the main tumor, we get a collapsed condition of the abdominal wall over the spot where the cyst has been evacuated, and the fact that after the tapping of the main cyst the small cysts still remain full is proof that we have to do with a polycystic growth. Now, when we tap a fibrocystic tumor of the uterus the walls do not collapse and sink in to such a marked degree as in a polycyst of the ovary. The fluid does not run out readily. The reason for this is that the walls are less elastic. Even with an aspirator you can draw out only a small quantity of the fluid from a fibrocystic growth.

The fluid from a monocyst or a polycyst, after standing for a time, does not change, but you will notice that the fluid drawn from a fibrocystic tumor contains a coagulum of lymph, for these tumors are enlarged lymph spaces. The fluid from an ovarian tumor will coagulate on the application of heat or nitric acid. The microscopic properties of the fibrocystic fluid are cells that bear a resemblance to broken-down blood corpuscles. When the dermoid tumor is tapped it sometimes collapses pretty thoroughly, but more frequently only partially. When this latter is the case there is an irregular mass left behind, in which we may detect, by palpation more or less solid material. The fluid is sometimes thin and entirely devoid of viscosity, and when examined in bulk has a bluish tinge. The specific gravity is light, and it is not coagulable by heat. In most specimens of fluid withdrawn from this variety of tumor there will be found floating on top of it a yellow, fatty material, generally collected in small masses, and usually there may be seen fine hair in it. In other cases hair will protrude from the canula or after the withdrawal of the instrument from the orifice of the puncture. In some other cases the fluid will be wholly fatty in character, very strongly resembling melted lard, which becomes hardened sufficiently to look like this same substance when cooled. I once tapped a tumor of this kind behind the uterus, and drew from it the watery fluid. One year afterward I tapped it again, and the fluid was wholly of the fatty character. When the parovarian tumor—the tumor of the broad ligament—is tapped, the abdomen collapses almost as completely as in cases of peritoneal dropsy. The fluid

runs out with great readiness, and in appearance resembles pure water. It has a very low specific gravity, from 1000 to 1005, and has no microscopic characteristics. It does not coagulate when nitric acid is mixed with it, or on the application of heat.

With reference to the microscopic appearance of the fluid, there is considerable difference of opinion. Many ovariologists do not place much reliance upon the cell formation found in the fluid, while others rely upon the microscope to decide in doubtful cases. I am inclined to believe in that cell described by Dr. Thomas M. Drysdale in Dr. Atlee's work on the Diagnosis of Ovarian Tumors.

THE TREATMENT OF POTT'S DISEASE BY THE PLASTER-OF-PARIS JACKET.

BY E. H. BRADFORD, M. D.

DURING the past three years many of the patients under my care at the Children's Hospital, suffering from caries of the spine, have been treated by means of plaster jackets. I have also applied this method to a few cases at the Carney Hospital and in private practice. The number in all amounts to forty; of these many have not remained under treatment for a very long time, but enough have been continuously observed for a sufficient period to warrant some generalization.

In a number of cases I have used Taylor's spinal splints, and a few have been treated by complete recumbency in a *gouttière de Bonnet*, or in bed. In avoiding exclusive treatment according to any one method I have been able to judge in a measure of the comparative merits of each.

In some cases by wearing plaster jackets there seemed to be little or no improvement from the treatment, and this where there appeared to be no doubt that the jacket had been properly applied. But in the main the evidence was conclusive as to the great benefit to be obtained from plaster jackets in suitable cases. This was evident in various ways; from the improved condition of the patients, their statement, or the testimony of parents and relatives.

In most of the cases the jackets were applied exactly according to Dr. Sayre's method. Suspension did not appear to have any serious effect; it was, however, always employed with care. Dr. Sayre's rule that suspension should not be carried beyond the point of relief to the patient is not generally practicable with young children, who are frequently too frightened to relate their sensation. In one adult suspension caused vomiting. In another adult fainting was said to have occurred during a previous application of plaster jacket. Nothing of the sort happened when the jacket was put on by me. During the first application, according to his statement, the patient, a heavy adult, was hung free of the floor for some little time, and fainted in this position.

Two children, who had worn plaster jackets for two weeks without discomfort, were attacked with dyspnea so severely that it was necessary to remove the jacket. The disease in one case was in the upper dorsal region, and the patient was wearing a jury-mast; in the other the disease was in the middle dorsal. One child was three years old, and the other six. The attack in the second case was quite alarming; the child lost con-

sciousness and became cyanotic, and the condition was only relieved by removing the jacket. A "dinner pad" was applied in both cases.¹ There was no paralysis in either case.

A third patient, on whom a plaster jacket was applied without a dinner pad, but after a hearty meal and a glass of milk, suffered so much the following night from difficulty in breathing that she could not lie down. After the application of a second jacket, with a dinner pad, there was no discomfort. In several cases I have made use of Dr. Reid's method of suspension with adhesive plaster,² which did admirably with children but not with adults. I have applied plaster jackets while the patients, if children, were supported, belly downwards, by the hips and shoulders, if adults between two tables, as recommended by Dr. Andrews;³ also according to Mr. Walker's and Dr. Lee's method.⁴ I was unable to see that the jackets put on in this latter way were less efficient than those made by Dr. Sayre's method. In one case of extreme curvature in the upper dorsal region, and apparently ankylosis, a plaster jacket was applied without suspension, the patient standing during the application, the object being to procure fixation. The jacket appeared to give a good deal of relief during the six months the child was under observation. In a second case, however, a jacket put on in this way did no good whatever, and was taken off the next day on account of the discomfort it occasioned.

Chafing can usually be prevented from becoming a serious trouble by carefully padding on each side of the prominent vertebral processes, and removing the jacket on any complaint of soreness, and reapplying with new padding. For pads I have found thick English saddler's felt more convenient than anything else. In three cases it was necessary, on account of eczema of the skin, to discontinue the treatment by plaster-of-Paris jackets. This was during very warm weather, and the patients were children in poor condition.

For bandages "crinoline muslin" is much better than "cheese cloth" or coarse cotton cloth. Coarse muslin, such as is used for mosquito netting, can be made, if rolled properly, to hold a good deal of plaster. This sets quickly, but is more liable to chip in use than the finer cloth. It can be used for a middle layer in a jacket.⁵

In suspending, Dr. Sayre's head-piece seemed more convenient than Mr. Golding Bird's or Dr. Glazier's.⁶ I found it an advantage to have the head-piece and the bar holding the straps under the axillæ connected with two different cords playing over different pulleys whenever it seemed advisable to regulate readily the strain on the neck and under the axillæ. Plaster jackets without a "jury-mast" appeared to be useless

in cases of disease of the spine in the upper dorsal region.

From many of the reported cases published from time to time, illustrative of treatment by plaster jackets, the impression is natural that every case of caries of the spine does well immediately on the application of a plaster jacket, and that this application is a comparatively easy matter. The experience at the Children's Hospital, however, has led us to believe that in no procedure in minor surgery is experience, care, and a knowledge of detail more important for the cure of the patient than in applying plaster jackets. We have also learned that some cases do not improve at all, even though the jackets are apparently well fitted. There can be no doubt that plaster jackets are dirty and clumsy. This is the price which is paid for an apparatus which is not dependent for its efficiency or inefficiency on the leniency or neglect of the attending nurse.

Exactly how plaster jackets are efficient in the treatment of caries of the spine is a question which seems to be still open for discussion. Opinions of writers on the subject differ. The usual idea is that suspension supplies the means of extending the spine, and that the plaster jacket keeps the spine in an extended position. The pelvis furnishes the base and the thorax the point of resistance for counter-extension. "On account of the conical shape of the trunk and the close manner in which all the interstices are filled by the dressing [plaster jackets], the spine is rendered straight and immovable." An apparatus⁷ has been devised by Dr. Stillman and Dr. Wyeth⁸ by which the rate of extension and counter-extension can be controlled mechanically. In discussing the efficacy of this apparatus, Dr. Hamilton⁹ stated that, although the "axe of the pelvis and the promontory of the sacrum" afforded a good basis of support, the point of resistance to counter-extension furnished by the thorax is not reliable, as the thorax, which is expanded during suspension, becomes smaller, "telescopes within the jacket, and all extension ceases" when the patient is not suspended. Dr. Shaffer¹⁰ writes, "It is absolutely impossible to apply a continuous extension and counter-extension which can be maintained with any degree of success. The change [during suspension] is apparent rather than real, and the great increase in height . . . is due to the extensibility of the unaffected structures and the obliteration and modification of the compensatory curves."¹¹ Dr. Hamilton thinks that if the patient is suspended no extension is made which reaches the seat of the disease.

Mr. Walker¹² believes that suspension is not a necessary part of the treatment. "That a jacket should be effectual it is a *sine quâ non* that it shall be applied when the spine is in such a position that the diseased vertebrae shall be free from all pressure. . . . This condition is found when the patient is suspended, . . . but also in an equal degree when the patient is laid flat on the back."

Some writers claim that the benefit of plaster jackets is that they furnish a means of fixation simply.¹³

⁵ Mr. Squires, of the Harvard Medical School, has found that a cylinder of plaster bandage, formed by rolling six layers of crinoline muslin (with plaster well rubbed in) around a bottle, and removing the bottle when the bandage is hard, will sustain a weight of one hundred and sixty pounds pressing upon either end without being crushed. A cylinder of the same number of layers of bandages of coarse cotton will be crushed under the weight of a few pounds.

To determine the effect of suspension on the spinal column I made the following experiment; being enabled to do so through the kindness and assistance of Dr. M. Richardson, assistant demonstrator of anatomy at the Harvard Medical School:—

A portion of the spinal column, consisting of six dorsal vertebrae, was taken from an adult cadaver, including the muscles and ligaments untouched, but not the skin. A stout iron wire was passed through the upper vertebra and another through the lower vertebra at the level of the articulation. The upper wire was fastened to a hook, and on the lower wire a weight was fastened, removable at pleasure. Two pins were driven into the bodies of the two adjacent vertebrae in the central part of the fragment of the spine, and the space between them carefully measured with a pair of compasses. If the two vertebrae were pulled apart this would necessarily be made greater. It was found, however, that after a weight of one hundred and ninety pounds was hung upon the lower wire the distance between the two pins remained precisely the same. The intervertebral cartilage between the two vertebrae was cut half through. When ten pounds were then hung upon the lower wire this space was increased one millimetre; when forty pounds were applied it was increased two millimetres; and when one hundred and ninety pounds, the increase was three millimetres. It was found that if the portion of the spine be bent backwards (towards the spinous processes), the weights having been removed, a slight amount of force, such as could easily be exerted by the hands holding on at each end of the portion of the spinal column, was enough to increase the separation of the pins two millimetres.

It would appear, therefore, that if the spinal column is straight and intact it will sustain practically any amount of weight without permitting the bodies of the vertebrae to be pulled apart. If, however, the column is weakened at any point between the bodies, the bodies at the weakened portions can be pulled apart. But the amount of this separation is no greater when a force of forty pounds is applied than when the spine is bent slightly backwards. If a healthy adult be placed in a suspension apparatus and suspension applied, just enough not to raise the heel of the person in the swing from the floor, it will be found that he has been elongated in height from one inch to an inch and a half. From the experiment just mentioned it is evident that this elongation cannot come from stretching of the ligaments; it therefore must come from the obliteration of the physiological curves of the spine.

The following facts show that straightening of the physiological curves in other ways will also increase the height. The height of two male adults in health was taken while standing erect. Their heights were sixty-seven and one fourth and sixty five and three fourths inches. They were then placed upon their backs upon the floor, their limbs kept straight, and their heels pressed upon the wood-work on the wall of the room, at right angles to the floor on which they lay. The lengths from head to sole were then measured, and found to be sixty-eight and one fourth and sixty-seven and one half inches. When placed upon their faces the measures were sixty-seven and one half and sixty-six and three fourths inches. The spine is evidently straightest when the body is lying upon the back; when on the face the arching backward of the spine, generally present in the erect position, is exaggerated.

In Pott's disease the spine is usually curved with the concavity forwards. The effect of suspension would be, if the laws of gravity were not interfered with by bony union or muscular action, to straighten the curve, and the bodies being on the concavity would be freed from pressure. If the disease were enough advanced to have separated the connection between the bodies by the intervertebral substance, and to have weakened or destroyed the anterior ligament, the bodies at the diseased point would be actually pulled apart, but only to a degree which could not be appreciated by ordinary measurement.¹

The amount which the bodies can be pulled apart is slight, and it seems as if that could not be maintained for any length of time, when the disease is in the dorsal or lumbar region, for the reason that, as Dr. Hamilton says, the thorax does not remain of the same size after suspension, and may readily "telescope" to the extent of a sixth of an inch within the jacket, no matter how tightly this may be applied, or how closely it might fit into the interstices between the ribs mentioned by Dr. Sayre. Suppose, however, that the thorax does not "telescope," and that the amount of force exercised during suspension does still persist after the jacket has become hard and the suspension is removed, this force must be exerted upon the pelvis as its base. The amount of this force would be equal to the weight of the body below the point of disease of the spine. In the case of a heavy adult, with the disease in the middle of the back, where suspension was complete (that is, when the patient was suspended so as to support no weight on the foot), the amount of this force would be between forty and sixty pounds. It seems impossible that the skin over the pelvis could stand for months this amount of pressure without sloughing. Dr. Shaffer believes that the change during suspension is due to the "obliteration and modification of the compensatory curves,"² and that the pathological curve is not affected. That the pathological curve is not changed in many cases is manifest. The benefit which may be expected from a plaster jacket, in these cases is that the spine, which is made as straight as possible before the jacket is applied, is prevented by the jacket from curving farther forward, as would otherwise inevitably happen. When the spine is curved, with the concavity forward, the weight of the head and upper part of the trunk acts like a weight on the end of a curved spring, and on any jar tends to increase the curve and the pressure at the diseased portion. This is less so the straighter the spine is, even if the pathological curve remain, and of course if the spine is bent with concavity backward the effect is reversed. In other words, the spine is held by an efficient although clumsy antero-posterior support. In certain cases the pathological curve is altered by suspension as by recumbency.

In disease of the cervical region the action of the jury-mast is that of simple suspension, with such fixation as the suspension effects. As the weight of the head is comparatively small, it is easy to imagine that suspension enough might be applied to "lift the bodies apart," and, what is probably more important, to prevent, on any jar, the head from falling forwards,

¹ Mr. Owen, British Medical Journal, February 28, 1880, mentions having experimented on the cadaver of a case of curves of the spine. He drove pins into the bodies of the vertebrae above and below the point of disease, measured this distance between, suspended the body, and found that there was no increase in this distance.

² Shaffer, Pott's Disease, page 40.

and by its weight curving the cervical spine and crowding the affected structures, that is, the bodies, together.

The ideal position for fixation in caries of the spine is not with the spine straight, but, if it were possible, with the spine above the point of disease curved backwards, so that the weakened bodies be not crowded together on the inside, but separated on the outside of the curve. This position is frequently assumed by patients in the early stages of Pott's disease, — the back is arched backwards and the head thrown back. In a case of this sort which lately came under my care, there was disease of the lower dorsal vertebrae and marked lordosis. While the jacket was applied the patient was not suspended, but was put in a position to increase this curve backwards. The relief caused by the jacket was very marked, the pain in the limbs and the inability to walk any distance disappeared entirely. The disease in this case, however, was at an early stage, and it seemed possible to separate the bodies of the vertebrae at the affected point more by exaggerating the position assumed by the child than by suspension.

The following patient illustrated the efficacy of a plaster jacket in preventing the spine from curving forward.

X —, a delicate, intelligent boy, ten years old, a patient of Dr. Moses Gunn and Dr. Andrews, of Chicago, with disease in the upper dorsal region, near the junction with the middle third, visited Boston for a few months during the summer. He was wearing a plaster jacket applied by Dr. Andrews. This consisted of an ordinary plaster jacket, to which an addition had been made which passed over the shoulders, encasing all above the ordinary jacket, except at the head and neck. This, of course, threw all the weight of the jacket upon the shoulders, and removed it from the pelvis, the base for extension. The boy had not worn a "jury-mast." On reapplying the jacket, the old one being broken, I determined not to add the shoulder part, thinking on theoretical grounds that it was unnecessary and injurious. The bandages were, however, put as high on the sternum as possible. Two days later the boy begged me to include the shoulders, as without that fixation he felt much less comfortable than in the old jacket, although it was much broken. After making this addition the jacket seemed to give the required support.

CASES.

The following few cases are selected as illustrating certain features of treatment: —

CASE I. is one treated successfully by means of plaster jackets. CASE II., unsuccessfully treated by plaster jackets. CASE III., previous treatment by plaster jacket not successful. Treatment progressing favorably with a Taylor's apparatus. CASE IV., treated successfully by absolute rest in bed, Taylor's brace, plaster jacket. CASE V., a light case, treated successfully by fixation of spine.

CASE I. H. A., aged four, patient at Children's Hospital. Caries in lower portion of the middle dorsal region of the spine. Treated for six months by confinement to bed. A plaster jacket was first applied by Dr. Ingalls in September of 1877. This was worn a short time. Child remained without treatment for several months. Patient reapplied for treatment in the spring of 1878. There was a sharp, angular projec-

tion; the child suffered pain, and walked with difficulty; there was contraction of the psoas and iliacus on the right side, and thickening could be felt deep in the right inguinal region, suggesting the formation of an abscess. The child was fretful; her condition had been becoming rapidly worse in the preceding two or three months.

Plaster jackets were applied, with suspension in the usual way at an interval of every two or three months. The improvement soon began to be quite marked. The treatment was continued up to the present time, one and a half years. The psoas contraction gradually disappeared, together with the thickening in the inguinal region. The child improved greatly in general health, attended school, and played about like other children.

At the end of a year the character of the projection had changed. Instead of a sharp, angular projection it became rounded, though occupying the same number of vertebrae (three), and without having increased in prominence.

The child has been without the jacket recently for a month or so at a time, and can walk about and stoop readily without it. She, however, wears a jacket (applied without suspension) as a precaution against a relapse.

CASE II. W., aged five, patient at the Carney Hospital, a scrofulous child with hip disease of several years' standing, with several sinuses discharging. Patient able to go about with crutches. A prominent spinous process discovered in the lower dorsal region, but no active symptoms were to be found; patient remained without treatment for nearly a year. A second prominent spinous process was then noticed below the first. Grunting respiration became marked at times. A plaster jacket was applied in the usual way, and the treatment continued regularly without intermission for nearly two years. The patient became gradually worse and died. At the autopsy, made by Dr. A. T. Cabot, no attempt at repair was found, the body of one vertebra being entirely, and another partially, destroyed.

CASE III. W., a boy aged four, was brought to me with caries of the spine in the middle dorsal region, which had been treated for a year at home by means of plaster jackets. The child was in a pitiable condition. The skin of the back and belly was chafed and covered with the scales of a dry eczema, with spots of a moist eczema. He was scarcely able to walk, was in a fretful condition, suffered from nocturnal pains, and had been becoming much worse during the past few months. A Taylor's apparatus for caries of the spine was applied. Improvement in the general condition became quite marked in a comparatively short time. The nocturnal pains gradually diminished, and finally stopped. The boy became able to walk about freely, and gained steadily in weight. He has now been under observation for eight months since the application of the brace, and has improved uninterruptedly during that time.

CASE IV. D., aged twenty-five. Caries of spine, lower dorsal vertebrae, with slight projection. A patient of the Carney Hospital, treated by absolute rest for two years. She was at first unable to sit up or move, though while in bed was free from pain. A Taylor's apparatus for caries of the spine was applied; the patient was then able to get up and walk about. This was worn for a year. Owing to a change of nurses,

the application of the apparatus was less carefully attended to at the end of that time, and she became somewhat worse. A plaster jacket was applied and worn by the woman for eight months without change. For several months the patient remained in the hospital under observation without treatment. She then returned home, and six months later reported by letter that she had remained well.

CASE V. A., girl, aged eleven. Caries of the spine in the upper dorsal region, with slight projection of two spinous processes, pains in side and hip. The patient was under the care of Dr. C. P. Putnam and myself. It was decided, instead of applying a jury-mast, to imbed in the plaster jacket, on each side of the spine, steel strips with a buckle at the top of each, and long enough to be a little above the shoulders. Straps were fastened into the front of the jacket and smooth wooden pads were secured, so that when the straps were buckled to the steel uprights pressure would be exerted just beneath the clavicle on each side. In this way quite thorough fixation of the spine could be made. The pain stopped on the first application of the apparatus, and the patient began to improve in general condition. The appliance was worn for a year and a half, being renewed every three months. The patient has now been without the apparatus for several months and her condition has remained excellent. The projection has not increased. The two spinous processes which were sharply prominent are much less so, but appear involved in a slight gradual curve.

CASE VI. The following case deserves mention. Mrs. G., aged twenty-five, a patient of Dr. Chamberlain, of Lawrence, was referred to me for advice. A sharp angular projection in the lower dorsal region was discovered, and a plaster jacket advised, but the patient declined. This was, however, afterwards applied by a medical student in Lawrence, and the bandages were subsequently renewed with great care by the woman's husband, who had but little money to spend upon physicians. After six months of treatment the symptoms of pain, which had been quite severe, had entirely disappeared, and the husband consulted Dr. Chamberlain as to the propriety of leaving off the jacket, as the woman considered herself well.

CONCLUSIONS.

The conclusions which I have drawn from the above facts are, that—

(1.) Plaster jackets are efficient in Pott's disease when the caries is below the level of the middle of the scapula.

(2.) The efficiency is not due to fixation alone, nor to extension, in the proper sense of the term, but to fixation in an improved position. This improved position is usually obtained by suspension, but also in many cases by recumbency.

(3.) The treatment by plaster jacket requires care in the application of the bandage. A poor plaster jacket will do harm, deceiving patient and physician.

— Dr. Sawostizki, of St. Petersburg, has improved the preparation of sticks of nitrate of silver. He melts together five parts of nitrate of silver with one part of nitrate of lead, forming an *argentum plumbonitricum*. Thus prepared the stick is not easily broken, and can be pointed like a lead-pencil.

RECENT PROGRESS IN PATHOLOGY AND PATHOLOGICAL ANATOMY.

BY E. G. CUTLER, M. D.

REMARKS ON THE PENETRATION OF PARTICLES OF DUST INTO THE AIR-PASSAGES AFTER TRACHEOTOMY.

IN examining a number of lungs from children dead of croup, where tracheotomy had been performed, Balzar¹ was astonished at the comparatively large quantity of particles of dust and other foreign bodies which he found in them. In some cases the surface of sections were black, as in a lung affected with anthracosis. These foreign bodies penetrate different parts of a pulmonary lobule, and often form real plugs, which almost entirely fill the alveoli. With a low power of the microscope they are seen to be distributed through the bronchi to a greater or less extent, and are also found in the exudation, in the walls of the alveoli and blood-vessels. The larger bodies remain isolated, while the smaller ones become imbedded in the protoplasm of the cells. The quantity of foreign particles varies; thus, in three cases where death occurred once forty-eight hours and twice thirty-six hours after operation it appeared large, while in three others it was much less. These bodies may be seen with the unaided eye as blackish plugs springing forth from the surface of a section after the lung has macerated for a while in alcohol. The cause of this striking appearance is probably to be found in the introduction of the canula, which excludes purification of the air in the mouth, nasal sinuses, and larynx; the child after operation is in the same condition as an animal whose larynx is paralyzed by section of the recurrent. Moreover, it is possible that the bronchial walls, having been rendered somewhat rigid through the pseudo-membranous deposit, have aided this entrance of these foreign bodies, while as no less weighty factors are to be mentioned the greater or less amount of dust contained in the air of the room, and also, from the defective ejection of mucus, the drying of the inner wall of the tube. Whether now the entrance of these foreign bodies into the air-passages is the only cause of the inflammation which appears in the lungs, or whether the diphtheritic bronchitis which is present in the lobular inflammations in by far the majority of cases does not play an equally important part, it would be difficult to determine. One finds just as often foci of lobular hepatization in the midst of those foreign bodies as in places where the latter have not penetrated. Next, it would be well to determine also whether many of the consecutive appearances after tracheotomy, namely, slight broncho-pneumonia and other affections of the lungs of an inflammatory nature, might not be referred to these penetrating irritants; and perhaps also in cases of croup without tracheotomy, as well as in many other diseases which interfere specially with the function of the glottis.

To prevent these occurrences and to guard against the penetration of such foreign bodies into the air-passages, it is necessary that children who have undergone tracheotomy should wear some porous substance covering the mouth of the tube, which at the same time also serves to warm the inspired air. In the selection of such a covering it is well to see that nothing be used which may of itself furnish dust. Then, too, the cleaning and airing of the sick chamber must be per-

¹ Bulletin de la Société anat. de Paris, 4 Ser. iii., page 72, 1878. Schmidt's Jahrb., Bd. 184, 1880.

formed with great care, and the throat be carefully covered meanwhile. Finally, it suggests itself to every one occasionally to oil the inner wall of the canula, so that any inspired particles of dust may adhere to it.

ATROPHY OF THE STOMACH.

H. Nothnagel¹ describes a case of *diminution in size of the stomach and disappearance of the peptic glands* with the clinical history of pernicious anemia. A shoemaker, twenty-three years old, for nine years had complained of disorder of the stomach, which manifested itself principally by occasional vomiting or nausea, loss of appetite, a feeling of fullness in the gastric region, and eructations. On being admitted to the hospital in May, 1878, he presented the appearances of progressive pernicious anemia; namely, striking pallor, great weakness, systolic heart murmur, scintillations before the eyes, retinal hemorrhages, small number of red corpuscles, no organic lesion. Later, irregular fever came on, and transitory right-sided hemiplegia was observed. In spite of arterial transfusion the patient died. The autopsy showed, besides extreme general pallor, hemorrhages in many internal organs. The stomach was twelve centimetres long, its greatest breadth six centimetres. At the same time its walls, and especially towards the pylorus, were very much thickened, and creaked on being cut. A microscopic examination of the stomach in the vicinity of the cardia showed that there was a loss of the peptic glands, while the mucous membrane was replaced by wavy fibrillary connective-tissue with few vessels. The muscularis mucosae and the submucous connective-tissue were very much thickened. In the vicinity of the pylorus, peptic glands were to be seen, but they gradually decreased towards the cardia with increase of the connective-tissue.

Although Nothnagel had correctly guessed at the diagnosis during life, yet in his analysis of the observations thus far published he arrives at the conclusion that one cannot get beyond a probable diagnosis. Moreover, we must carefully distinguish three anatomical conditions: (1.) Simple atrophy of the peptic glands without change of the gastric wall or of the size of the stomach. (2.) Cirrhosis of the gastric wall with diminution of the cavity of the stomach, without special change of the peptic glands. (3.) Cirrhosis of the stomach and atrophy of the peptic glands.

HYPEROSTOSES CONSECUTIVE TO OBSTINATE ULCERS OF THE LEG.

Dr. Paul Réclus publishes a careful study² based on the observation of cases. His conclusions are these: (1.) Ulcers of the leg may give rise to divers forms of osteo-periostitis in the subjacent bones. Exceptionally destructive, the inflammation most frequently determines increase of volume; the bone is then light and spongy, covered with osteophytes. In very rare cases, the tissue of the diaphysis is hard and eburnated, the medullary canal obliterated or narrowed. (2.) When the epiphyses are not yet joined, the bone increases in length, and may exceed its fellow by from two to three centimetres. The osteophytes are more abundant. A vertical osseous diathesis may manifest itself, which is shown by the ossification of the aponeuroses of the ligaments of the vascular and nervous sheaths; in a word, of all the fibrous tissues of the leg.

(3.) From the centre of the ulcer prominent exostoses sometimes arise. These have been taken for syphilitic lesions, but the consistence of the tumor and specific treatment will establish the diagnosis. (4.) Osteo-periostitis is a grave complication. It is inimical to the cicatrization of ulcers, compromises the nutrition of the limb, and very often renders amputation necessary.

WOUNDS OF THE LIVER AND KIDNEYS.

Dr. H. Tillmanns³ published a report of experimental and anatomical researches on wounds of the liver and kidneys. The essay consists of two parts, the first dealing with the dangers from hemorrhage in cases of injuries of the liver and kidneys, and the second with the finer anatomical details of the healing of wounds treated antiseptically.

In investigating the first point, the abdominal cavities of rabbits were opened, with antiseptic precautions, and one or more wedge-shaped portions were cut from the liver or kidney. No attempt was made to arrest the hemorrhage, the wound in the abdominal walls being at once stitched up. In twelve animals portions of the liver were thus removed, and, in nine, portions of the kidneys. Of these, none died. The bleeding from the liver was found to be very slight; thus, when the abdominal cavity was examined twenty-four hours after the removal of from two to four wedge-shaped portions (two and one half centimetres in length and one centimetre in thickness) of liver, the wound was found filled up with blood, but there was rarely a trace of blood in the abdominal cavity. The healing of these injuries was complete in from five to ten days. In the case of the kidney the hemorrhage was much more severe, but, nevertheless, no animal died, and here also the healing was perfect after five to twelve days. In man Tillmanns has likewise observed that the hemorrhage from wounds of these organs is but slight, unless some large vessel be injured.

The question to be determined with regard to the healing of these wounds was, whether the white blood corpuscles, or the special cells of the liver or kidney, or the fixed connective-tissue cells, played the chief part in the healing process. The possibility of any participation in this process by the special cells was completely shut out by the following method. Portions of the liver, kidney, spleen, and lungs of rabbits were removed, and kept in absolute alcohol for two or three weeks. Wedge-shaped portions were cut out of these. They were then washed in two and one half per cent. watery solution of carbolic acid, and introduced, with antiseptic precautions, into the abdominal cavity of rabbits. Twenty animals were experimented on in this manner, and of these two died. When examined twenty-four hours after their insertion, the defects in these portions of dead tissue were generally found to be completely filled up with a glutinous mass, which was seen on microscopic examination to consist of white blood corpuscles. These also completely surrounded the dead tissue, and caused slight adhesion of it to some part of the abdominal wall or contents. One or two days later the migration of the corpuscles had become more marked; they had penetrated in all directions into the dead tissue, following, as a rule, the spaces of the cellular tissue; at the same time, in the

¹ Deutsches Archiv für klinische Medicin, xxiv., s. 253.

² Progres medical, December 29, 1879. London Medical Record, February 15, 1880.

³ Virchow's Archiv, Band lxxviii., page 437. London Medical Record, February 15, 1880.

older parts, formation of blood-vessels and connective tissue could be observed. If the infiltration of the dead tissue with these corpuscles goes on rapidly, the former soon disappears, leaving only a small thickened spot behind. In one or two cases, however, it became converted into a cheesy mass, owing, as Tillmans supposes, to too rapid infiltration with cells.

Examined more carefully, the cells next the dead tissue are seen, even after twenty-four hours, to be spindle-shaped, and in two or three days vessels are present both in the defect and also over the whole surface of the dead tissue. At the same time the colorless corpuscles are seen to increase in volume, their protoplasm then splitting up into fibrillae, while the nucleus remains with a small quantity of protoplasm around it. In other parts the corpuscles seem to melt together, and large granular nucleated masses are thus formed. Tillmans looks on these giant cells as merely masses of formative material which may develop to connective-tissue or blood-vessels, or may undergo degeneration. The vessels are formed by processes starting from previously existing vessels. These offshoots are at first solid, consisting of white corpuscles which have become massed together outside the wall of the vessel. They send out smaller branches, which anastomose with each other and with processes from the large formative cells previously mentioned. These various offshoots ultimately become hollow, and communicate with the vessels. Tillmans deems that these processes proceed from cells forming the walls of the vessels, as was previously supposed.

As to the origin of these cells, he considers that they are white blood corpuscles; at the same time he admits that these experiments do not absolutely prove that the fixed connective-tissue cells do not take part in the process. To see if this is the case or not, he inclosed the piece of dead tissue in a glass case having two lateral holes, and introduced this into the abdomen. Here also the tissue became infiltrated and the glass case surrounded by similar cells, which he therefore regards as white blood corpuscles. The special liver and kidney cells take no part in the healing process.

Similar results were obtained when the healing of the injuries to the liver and kidneys was investigated. Here also the same migration of leucocytes, the same large, irregular formative cells, the same processes of fibrillation and vascularization, were observed. The special hepatic and renal cells were quite passive, and underwent fatty degeneration in the neighborhood of the wound.

Exactly the same observations were made on portions of catgut introduced into the abdominal cavity, and Tillmans concludes that the same process occurs in the removal of silken ligatures, of the pedicle in ovariectomy, and of dead bone. In the case of the latter, he supposes that the carbonic acid in the blood dissolves the earthy salts, leaving the animal basis to be served in the same manner as the catgut.

(To be concluded.)

— An unusually large number of medical men go from New York city to Europe this summer, the list including, among others, the names of Drs. Fordey Barker, Vanderpool, Alexander B. Mott, Keyes, Noeggerath, Lincoln, Weir, McBride, and H. F. Walker.

Hospital Practice and Clinical Memoranda.

BOSTON CITY HOSPITAL.

MEDICAL CASES IN THE SERVICE OF DR. HALL CURTIS.

ULCERATIVE ENDOCARDITIS; THROMBOSIS; EXTENSIVE GANGRENE.

C. D. K., forty-six years old, nurse, entered on November 23, 1879, in the service of Dr. Stedman, with a history of intermittent fever (quotidian) while in army. He also had subacute rheumatic attacks. In September had an attack of probable cerebral embolism.

November 19th had chill, followed by fever and sweating, with sharp pain in small of back. Two days later a similar attack. Morning of entrance a third attack, with severe headache and vomiting. Temperature after chill 104° F. Heart and lungs normal. November 24th. Quinine, five grains every three hours. November 25th. Slight chill; in the evening became deaf. Quinine omitted. December 1st. At noon severe chill, pain in epigastrium, and vomiting. December 3d. A similar attack. December 4th. Quinine, five grains, subcutaneously. A faint but distinct presystolic murmur heard at apex; no thrill. December 5th. Nervous; pain in abdomen, and moderate bleeding from hemorrhoids. December 7th. Complaints of pain in legs, where quinine was injected. December 11th. Diarrhea. December 15th. Pain in left ankle. December 17th. Chill last night; another this afternoon. December 19th. Urine opaque, acid; specific gravity 1026; slight trace of albumen; occasional pus and blood corpuscles; no casts; squamous epithelium. Another chill this afternoon. December 21st. Slight chill this r. m. Pain shooting up outer side of left leg from ankle. December 29th. Condition remains the same. Has had several chills, with epigastric pain and vomiting. Presystolic souffle very distinct. January 4th. Service of Dr. Curtis. Had severe pain in right leg during night. The leg below knee is cold; sensation lost; cannot move toes. No pulsation in tibial artery. Pulsation in femoral, in Scarpa's triangle, normal. Eleven a. m. Pulsation in femoral much feebler. Severe pain in leg. January 5th. No pulsation in right femoral. January 6th. Right radial feebler than left; arm cold. Tongue protrudes to the left. January 9th. Spots of gangrene on right leg. January 10th. Marked discoloration from knee down leg, including toes, with œdema. January 12th. Several bullæ on leg, which has become more discolored. Has slight aphasia. January 13th. Has been in same semiconscious condition, with the exceptions of paroxysms of dyspnea for two or three days. Has two spots on anterior aspect of left arm, one above, the other below, elbow-joint; these were the size of the end of one's finger; having a yellow centre and a bright red circumference, well defined; probably small spots of circumscribed gangrene from minute emboli. January 14th. Slight pulsation in right femoral. January 16th. Died. Autopsy by Dr. Cutler, eight hours after death.

Lungs. With the exception of slight adhesions on lower part of right lung, the pleural surfaces were free. Section of lungs showed bronchial tubes considerably filled with thick mucus. Bronchial mucous membrane injected, but not thickened. Some injection of lower portion of lungs, and a little œdema.

Heart. Pericardium adherent, adhesions old and fibrous; left ventricle hypertrophied and consistency diminished. Auricular surface of posterior curtain of mitral valve was the seat of an ulcerated roughened endocarditis, with deposit of lime salt at base, and some fibrinous vegetations. Aortic valve was somewhat thickened on the right curtain. Coronary artery healthy. Color of heart pale. **Liver,** aside from small amount of fatty infiltration, was not abnormal. **Spleen.** In upper part of spleen there was an old hemorrhagic infarction, of a yellow color, and caseous consistency. The size of this infarction was about the size of a silver half dollar. In different parts of the organ there were smaller ones. **Kidneys** large, and in the cortical portion in a state of parenchymatous inflammation. In the lower part of each organ were several embolic infarcts. **Intestines** and **stomach** not abnormal. **Iliac artery.** At division between the iliaes there was a small riding embolus, which did not completely obstruct the calibre of the vessel.

DISPLACED HEART.

R. P., aged forty-three, seamstress, entered the City Hospital February 16th, with ill-defined history of lung trouble, of eleven years' duration. Six months ago she had severe pain in the right side, lasting two weeks, and occasionally recurring since. For past two months has been gradually failing, and gave up work one week before entrance. For three weeks she had

1. Dullness above this line more marked.
2. Area of heart dullness.
3. Apex beat.
4. Area of commencing liver dullness.

had cough; scanty expectoration. Hemoptysis one year, and also six weeks, ago. Persistent diarrhoea for four weeks. Catamenia irregular, last month excessive. Urine, color pale; specific gravity 1025; albumen, faint trace; sugar, none; sediment contained some pus corpuscles and octahedral crystals of calcic oxalate in large numbers; no casts.

Physical examination. Dullness throughout right front, with medium-sized moist râles; left front hyperresonant with exaggerated breathing. Right back dull, in upper third, bronchial respiration; moist râles throughout right back. Respiration through left back somewhat distant, with stridor. Heart's impulse between right nipple and sternum. From fourth rib to

second, on right side, is a well-marked murmur and thrill; there also is apparently a double murmur at base.

February 22d. Is improving. Physical examination by Dr. Dunbar, senior house physician. Slight dullness at extreme left apex in front; remainder of left chest very resonant. Dullness over upper half of right back and in front, as shown in diagram. Medium-sized moist râles over right chest, front and back. Over back the râles are more numerous at base, but in front are more numerous at apex, also heard about two inches to left of sternum. Bronchial respiration over area of dullness, higher pitched behind. Marked pulsation in second, third, and fourth right intercostal spaces, where a thrill is heard (presystolic). First sound is heard most distinctly in fourth right intercostal space, two inches to right of median line. In third intercostal space a presystolic murmur is heard. No oedema of feet. No venous pulsation. No thrill in vessels in neck.

ULCER OF STOMACH.

P. K., twenty-seven years old, car driver, entered hospital March 11, 1880. Six days before entrance was seized with pains in his back and belly, accompanied by vomiting. These symptoms have been persistent. The attack came on suddenly, he states, after a severe exertion. Patient seems exhausted, with feeble pulse, and cold extremities; constant retching.

Physical examination: Tenderness in epigastrium and right iliac fossa, where a sense of resistance is felt; abdominal walls thick and doughy; muscles rigid; no tympanitis; no hernia.

March 12th. Turpentine stupe; milk and lime-water; morphia, *pro re nata*. Vomiting constantly a yellowish fluid. March 13th. Vomitus now has coffee-ground appearance. March 14th. More prostrate. March 15th. Vomitus looks like liquid feces, and has fecal odor. Unable to retain nourishing enemata. March 17th. Died. Autopsy by Dr. Cutler twelve hours after death.

Heart not abnormal. **Lungs** contained blood which had evidently been breathed in during the struggles of patient. This was in dependent parts of lung. **Stomach** had a perforation in anterior wall, near the pyloric orifice, about the size of a quarter of a dollar. A vessel of large size had been eroded, and general peritonitis had ensued. Apart from being anæmic, the other organs were normal.

GENERAL TUBERCULOSIS.

R. H., aged forty-two years, house-keeper, entered on January 13, 1880. Family history good; has generally been healthy, with the exception of an occasional epileptic attack. For three months has had severe cough. Past two weeks complains of pain and distention of abdomen, pain and oedema of legs. Otherwise history not important.

An occasional fine moist râle after cough all over chest. Soft systolic souffle at apex, propagated into axilla. Not heard at angle of scapula. Dullness and fine moist râles heard over lower half of both backs; left side of chest fuller than right. Faint systolic murmur heard over aorta, propagated into carotids and subclavians. Abdomen distended and tympanitic throughout. No fluctuation. Feet and legs oedematous. No albumen in urine. Improved till February 2d, when abdomen became more distended, with pain

and increased dullness in region of liver. February 14th. Since last record has had involuntary discharges, with constant abdominal pain, and excessive tympanites not relieved by rectal tube. Complains of numbness in arms and legs.

Urine, color high; specific gravity 1014; reaction when fresh, alkaline; albumen, a trace; some pus; round and squamous epithelium in large quantities.

February 29th. Is worse. Delirium constant. March 11th. Abdomen greatly distended, fluctuation well marked. March 19th. Abdomen aspirated with relief.

March 25th. Died. Autopsy eight hours after death.

Heart. Evidence of endocarditis more or less recent on mitral and tricuspid valves. Mitral admitting little finger-tip. Aortic valves normal. *Lungs* firmly bound by old adhesions, particularly at base. Tubercles everywhere. *Pleural cavities* contained one hundred ounces of bloody serum; pericardium four ounces of fluid; peritoneal cavity ninety ounces of clean yellow serum. *Spleen* slightly enlarged; engorged; tubercles. *Kidneys.* Tubercular nodules. *Liver.* Capsule greatly thickened. Nutmeg atrophy. *Ovaries.* Cyst size of walnut in each, containing thick bloody material. Abscess in left Fallopian tube. Contents of peritoneal cavity firmly glued together, with tubercles everywhere.

Reports of Societies.

PROCEEDINGS OF THE SUFFOLK DISTRICT MEDICAL SOCIETY.

T. M. ROTCH, M. D., SECRETARY.

MARCH 27, 1880. The president, DR. CALVIN ELLIS, in the chair.

SCARLET FEVER.

DR. J. B. AYER read the following paper:—

Miss L., a bright girl of seven, from a very early age was known to have chronic enlargement of the tonsils, and was frequently subject to acute inflammation of the throat. The attacks of acute tonsillitis were sometimes severe, and caused dyspnoea.

In the fall of 1877 I prescribed inhalations with an atomizer, and applied a nitrate of silver solution to the throat, to the little patient's great relief. However, in the spring of 1878, so severe had the attacks of tonsillitis become, and so urgent the distress in breathing, I deemed it necessary to remove with the tonsillotome a large portion of the right tonsil, which had always been the more obstinately swollen. Although every precaution was practiced inflammation ensued, and during the week following the operation the dyspnoea was as severe as before. It subsided at the end of that time, and during the next eight months she had little throat trouble. Fifteen months ago the tonsils again began to inflame, the right somewhat more than the left. There was no improvement during the spring. In June I removed with the tonsillotome as much as possible of the left tonsil, and also as much of the uneven remnants of the right as the instrument could be made to bring away. There was no subsequent inflammation nor important throat symptoms up to the present illness.

December 16th last she complained of cold chills running down the back, but felt able to attend school.

She woke the next morning feeling chilly. Her parents noticed that she was feverish, and that there was a slight redness of the neck and body, the color becoming more marked during the day. When I saw her (the same evening) the pulse was about 120, and temperature 103° F. The tonsils were not swollen; there was moderate pharyngitis.

On the 18th the eruption had become more marked upon the body, but did not appear upon the face; the disease very mild up to this time.

On the 19th the tonsils were found much swollen, and the respiration noisy, accompanied by dyspnoea, which was in part relieved by inhaling tr. iod. co. c. tr. opii camph. by the atomizer. There was marked hyperaesthesia; she invariably complained of pain when the thermometer was placed and held gently in the axilla.

On the 21st both tonsils were swollen and covered with patches of exudation, which seemed molded to the surface. They were brushed three times daily with an eight per cent. solution argent. nitrat., and large pieces of diphtheritic membrane were detached. There was severe laryngitis. The glands and subcutaneous tissues on both sides of the neck and below the jaw were greatly swollen, and growing hard and tense. She began to be delirious, talking much about her school, reciting her lessons, and frequently raising her hand to attract the teacher's notice.

On the 23d it was found that the diphtheritic symptoms had increased in severity, in spite of frequent inhalations. Dyspnoea was more marked; the face had a dusky appearance; air scarcely entered the lungs on account of obstruction of the throat; the parotids and other glands continued swollen and hard; coryza was present. It was feared that tracheotomy might be required.

On the 24th I brought away several foul pieces of diphtheritic membrane from the right tonsil (the one twice operated upon, and which from the beginning of the present attack had presented the more malignant appearance). On two occasions there were slight hemorrhages from the irritated tonsils.

Up to this time the temperature had ranged between 103° and 104° F., and the pulse between 120 and 140. The same evening (24th) she had two well-marked convulsions, each lasting a few seconds. Later in the evening she took nourishment, and seemed no worse.

On the next day (Christmas), the ninth day from the first appearance of the eruption, the redness had entirely left the body. The purulent nasal discharge persisted, and the tonsils were still inflamed, but the diphtheritic patches had disappeared, and there was less dyspnoea.

While the characteristic appearances of scarlet fever and the diphtheritic complication had yielded, I was surprised to find the fever continue and also many typhoid symptoms beginning to present themselves. The tongue became dry, was thickly coated, seemed too large for the mouth; there was sordes and tenacious mucus in the fauces, and the lips were swollen, dry, and cracked. There was cerebral congestion requiring the constant use of cold-water dressings. She remained delirious, her mind still running upon her duties at school. For several days she lay in a state of stupor, from which, fortunately, she could be aroused to take nourishment.

From the ninth to the twenty-fourth day there was no decided break in the fever, and up to the twenty-eighth day her condition was not sufficiently assuring

to warrant Dr. James Ayer (who saw her in consultation) or myself in pronouncing her out of danger.

From the ninth day the temperature was taken by a careful nurse; the fluctuations, which were very frequent in the course of twenty-four hours, are well shown by the chart. It will be seen that the highest temperature ranged between one and ten P. M., the lowest between five and ten A. M. The pulse did not follow closely the temperature: it ranged between 104 and 140.

On the tenth, eleventh, and twelfth days of the disease all the discharges from the bowels were involuntary, and the urine was passed in the bed. She lay in a state of stupor, from which she could always be roused with considerable difficulty.

During the twenty days of fever following the convulsions, every effort was made to keep up the little patient's strength without causing too much annoyance. Half an ounce to two ounces of liquid nourishment were given at frequent intervals, and during two days only was there marked irritability of the stomach. Except upon these two days we succeeded in giving her every twenty-four hours twenty-four ounces of milk, the *juice* from a pound of beef, or *broth* from a pound of mutton, together with eight teaspoonfuls of brandy and six grains of quinine.

During this period the inflammation of the tonsils and the dyspnoea gradually diminished, and the laryngitis gave place to bronchial catarrh. The glandular swelling gradually disappeared under the use of flaxseed poultices. The tongue became again of its usual size, and the aphthous spots on the edges disappeared.

There was no kidney trouble from the outset, though at times little urine was passed.

On the thirty-fourth day she was lifted to a couch while the bed was made. On the forty-fifth day she sat up in an easy-chair four hours, and was able to walk a few steps. At the end of the eighth week she could walk around the room several times, but became easily tired. She has made a full recovery.

The rise in temperature on the thirty-fifth day could not be explained, as there seemed to be steady improvement at that time.

On the forty-seventh day the bran-like desquamation had not entirely disappeared from the soles of the feet. In the fifth and sixth weeks she suffered from rheumatic pain in the joints and spine.

Deafness, which was marked during the first five weeks, steadily disappeared after that time without treatment.

During convalescence and since she has taken tart. ferri et potass. with cinchona.

Very briefly to recapitulate, the little patient, after an incubation period of twenty-four hours, was taken down with an apparently mild form of scarlet fever; but on the third day the tonsils became swollen, and on the fifth and eighth days inclusive there were severe diphtheritic symptoms, with dyspnoea.

On the eighth day, after eruption had disappeared and throat symptoms were nearly over, convulsions appeared, followed on the ninth day by typhoid symptoms, with stupor, involuntary evacuations and urine, the fever and a portion of the dangerous symptoms not entirely disappearing before the twenty-eighth day, and convalescence not being fully restored before the end of the eighth week.

I would call attention to the severe character of the diphtheritic complication in this case. West says,

"Scarlet fever presents itself in one case so trifling as scarcely to interrupt a child's cheerfulness even for a day; in another it is so deadly that medicine is unable to stay its course even for a moment."

The larger proportion of my cases have belonged to the mild type, the angina and eruption both having disappeared by the seventh day, and convalescence being complete ten days after the eruption was at the height. My principal duty in attending these cases was to be on the lookout for deafness or renal complication.

On the other hand, I have seen four malignant cases, in all of which there was great dyspnoea. One of these was a boy, three years old, who died on the third or fourth day of the disease of diphtheritic tonsillitis, the eruption at the time of death being at its height.

The other three cases occurred in the same house. First, a girl, two and one half years old, was taken ill. On the second day she was removed from the basement to the attic, and there died on the fourth day. The eruption covered the face and body at the time of death.

The next victim was one and one half years old, and lived on the second story. She was said to have kissed the first child when dying, and was taken ill fourteen days later. She died on the fourteenth day of the disease, the eruption not having entirely disappeared.

The third patient was four years old, and lived on the third floor. She was taken ill at least thirteen days after the last-mentioned patient, and died on the seventeenth day.

They all had great dyspnoea from severe tonsillitis, which was probably diphtheritic in character.

The cerebral symptoms accompanying scarlet fever are worthy of close attention. Malignant cases of scarlet fever, showing from the outset high fever, cephalalgia, and delirium, passing rapidly into coma, and proving fatal in two or three days, are not uncommon; but cases like the one reported, in which the disease was in the beginning mild in character, but gradually developed delirium, convulsions, typhoid-like symptoms, and stupor, are rare, and seldom end in recovery.

J. Lewis Smith says, "I have never seen nor heard of any case which recovered when convulsions occurred after the complete development of the eruption."

Rilliet and Barthez state that they have seen recoveries in cases where the intelligence of the patient has been very much disordered; but of those who, during the first fifteen days of scarlet fever, were taken with convulsions, convulsive movements, contractions, in a word, any symptom affecting the locomotor apparatus, all, without exception, died.

Such prognosis, according to Gee (Reynold's system of medicine), is too unfavorable, although the symptoms have grave significance.

Meigs and Pepper state early convulsions generally indicate a fatal attack, and that prolonged delirium and persistent elevation of temperature are very unfavorable symptoms. "Typhoid scarlatina" is the name given to cases of scarlet fever where the febrile symptoms persist, and are accompanied by headache, delirium, thirst, and dryness of the tongue, the local lesions of the disease becoming subordinate.

All authors agree that there is no enlargement of the spleen, nor intestinal lesion, nor typical tempera-

ture in "typhoid scarlatina," and that, apart from borrowing a few of the symptoms of typhoid fever, it has nothing in common with that disease.

Finally, I cannot but feel that the recovery of our little patient was in a great measure due to the persistence with which nourishment and stimulants were given.

DR. BLODGETT asked about the frequency of true diphtheritic disease in scarlet fever. — DR. AYER thought that the frequency was rather greater than three or four in eighty cases.

MEDICAL SOCIETY OF THE COUNTY OF NEW YORK.

THE USE OF NITROUS OXIDE GAS IN CERTAIN DISEASES OF THE NERVOUS SYSTEM.

At the last meeting of the New York County Medical Society, April 26th, a paper on the above subject, written by Dr. Allan McLane Hamilton, was read by the secretary in Dr. Hamilton's absence. The author first spoke of the physiological effects of the agent, and gave a *résumé* of the history of its therapeutical use, referring particularly to the experiments of Mitchell and Ziegler. The latter found it of service, not only as a tonic and diuretic, but also as a stimulant in poisoning by such agents as carbonic acid gas, as well as in other depressed conditions of the system.

For the introduction into this country of its scientific medicinal use, he said, the profession was indebted to Dr. J. Ellis Blake, of New York, who had made much diligent research in the subject, and who had sufficiently demonstrated that in nitrous oxide gas an important addition was made to the materia medica.

Personally, Dr. Hamilton had employed it with a very encouraging degree of success in many cases of depression of spirits, insomnia, neuralgia, melancholia, and hypochondriasis, and he regarded it as a nervous stimulant of great value. It was found to increase the activity of the heart and the arterial tension; while if its administration were carried sufficiently far it would, of course, produce its well-known effect of temporary unconsciousness, with anaesthesia. He had obtained it in the liquid form from the Messrs. Johnston, of New York, and the purity of the article furnished by them was entirely to be depended upon. As a rule, he made use of two gallons of the gas to one gallon of air. The writer then went on to speak further of the effects of its administration upon the system. The temperature, he found, was not very much disturbed by it, though one of the good results usually produced by it was an increased warmth of the extremities, and its general effects were somewhat similar to those of oxygen, as these were demonstrated by the investigations of Dr. A. H. Smith. On account of the exhilaration of spirits caused by it, it was of great service in many nervous and mental disorders, and under its use in his hands taciturn and melancholic patients had often become contented and cheerful. In melancholia dependent on disturbance of the menstrual function, as well as in various forms of hypochondriasis, it had proved very useful, and mention was made of two subjects of melancholia in the insane asylum on Blackwell's Island, who had not eaten any food voluntarily for two weeks, but went to the table cheerfully and ate with alacrity after having had the nitrous oxide gas administered to them.

The susceptibility to its influence varied very greatly in different individuals, and Mitchell had found that in some instances no less than four gallons of the gas were required before any symptoms whatever were produced.

When there was any tendency to mania present, it should never be given, as it either proved negative in its results, or else aggravated the condition. — the latter being more frequently the case; nor ought it to be used in any case where there is organic disease of the heart. It was also contraindicated whenever there was a plethoric state of the system, on account of its effect in increasing arterial tension. In anæmic conditions, on the other hand, it was frequently of the highest service. In a case of amenorrhœa (without appreciable disease of the uterus), accompanied by very severe headache, it had acted most happily; and in several cases of sick-headache it had not only successfully broken up the attack, but had also had the effect of preventing a return of the trouble. So in hemicrania, facial neuralgia, and sciatica, as well as in many cases of insomnia, it had also proved very useful. When given for the relief of the latter condition it had been found best to administer the gas in the middle of the day, instead of just before retiring. In cases of insomnia where there was cerebral hyperæmia, however, it was contraindicated, as would naturally be supposed from what had been previously stated of its effects. Those suffering from functional heart trouble and chlorotic young women were very apt to be much benefited by it; and the same was true of individuals who had used tobacco to excess. Finally, a very useful application of the gas was in the case of those addicted to the use of alcohol or opium, and who had been induced to give up their accustomed stimulus.

At the conclusion of the paper, Dr. Blake made some remarks, in the course of which he stated that he had been induced to make a series of experiments with nitrous oxide gas in consequence of the results from its use which a dentist of Memphis had reported three years ago. Before undertaking an investigation of the subject he had also obtained a report from the superintendent of an insane asylum in Connecticut of the results which had been observed from its use for fifteen months in that institution. The only claim for originality that he could make in the matter was perhaps in regard to the method of inhaling the gas, which he believed to be a point of considerable importance. He had found that it was advisable that once in from three to five respirations the patient should be permitted to take a full inspiration of atmospheric air. In this way the gas was taken in smaller doses, and had the effect of a gentle stimulant, without producing intoxication at all. If in any case during the inhalation flushing of the face or any evidence of intoxication were observed, even a larger amount of air should be admitted. He ordinarily found that, administered in such a manner, one bag of gas was sufficient for a sitting.

The remedy he regarded as a diffusible stimulant and tonic, the employment of which was followed by no depressing reaction, and he thought its effects on the system were comparable to those of a sea-voyage or of a trip to the mountains. His experience with it had been entirely confined to the limited field of private practice, as the state of his health had not permitted him to carry his investigations further, and therefore he was much pleased to hear such a favorable

report of the more extended use of the agent by Dr. Hamilton. Personally he had employed it with excellent results in cases of insomnia, melancholia, anorexia, and nervous exhaustion. Its good effects seemed to be entirely confined to anæmic and asthenic subjects, and he had never seen it prove of any service in the case of plethoric individuals.

When Dr. Blake had finished his remarks he exhibited and explained the latest and most approved form of portable apparatus for supplying the gas, as now manufactured by the Messrs. Johnston, after which there was some further discussion of the paper.

Later, a paper on the Use of Cerium Oxalate for the relief of Cough was read by Dr. Hobart Cheesman.

Recent Literature.

The Venereal Diseases, including Stricture of the Male Urethra. By E. L. KEYES, A. M., M. D., Professor of Dermatology and Adjunct Professor of Surgery in the Bellevue Hospital Medical College, etc., etc. New York: Wm. Wood & Co., 27 Great Jones St. 1880.

But one third of this year has elapsed, and already dermatological literature has been enriched by a volume from the busy pen of Kaposi: a fifth edition of Neumann's text-book; a treatise by V. Sigmund, and one by Fournier; a student's manual by Morris, and another by Sturgis; a monograph by Leonard, and this one by Keyes; while the second edition of Dühring's admirable work is nearly completed, and Bumstead and Taylor's fourth edition of Bumstead's Treatise barely escapes being included. Dr. Keyes is well known as coeditor with Dr. Van Buren of an excellent work, published in 1877, upon the Surgical Diseases of the Genito-Urinary Organs, including Syphilis, and as the author of an interesting little book, published the same year, embodying original observations upon the effects of small doses of mercury, entitled *The Tonic Treatment of Syphilis*.

The present volume is one of a series addressed to the general medical practitioner, and designated as Wood's Library of Standard Medical Authors. It contains three hundred and forty-eight pages, fifty-two devoted to the simple venereal ulcer, the so-called chancreoid; one hundred and ninety-six to syphilis; and ninety-four to gonorrhea and its complications. There are also forty-one wood-cuts, mostly old friends, which have done yeoman service in many books of many men, and which are of value when illustrating shapes and styles of instruments, but are heartlessly and hopelessly depressing if employed to represent dermatological lesions. The mere localization of an efflorescence can be as well described by words, and the memory remains unlogged by a mental picture misleading in its details. We had hoped that the fiasco of Hardy, over ten years ago, had settled this point forever. The text, however, of which the illustrations of disease are not worthy, is what one expects from a writer like Dr. Keyes. It is the knowledge thus far obtained upon the subject thoroughly collated, judiciously arranged, sensibly expressed, and enriched by the results of personal observation. Perhaps less space might have been advantageously devoted to arguing for a distinction between the virus of syphilis and that of the simple venereal ulcer, an accepted fact and a dead issue, while a little more could have been with propriety said upon the

question whether the simple venereal ulcer possesses a specific virus of its own; why the chancreoid is followed by a chancreoid bubo, a simple bubo, or none at all; why the endothelium of the lymphatic vessels does not become chancreous; why the virus (?) stops always at the first gland station, etc. We could wish also to find among the many books now published upon syphilis one which would boldly substitute new and more truthful terms. "Duality in syphilis" means really unity in syphilis, or the existence of *one* distinct peculiar virus, shown by its clinical manifestations to be entirely unlike any other virus. The duality is in the two varying natures of specific and non-specific ulceration, according to modern medical Manichees. The "mixed chancre" is no more what it would imply than a beaten egg is a glass of egg-nog. The "mixed chancre" means a union of totally different things. There are two separate poisons existing side by side, and one of these is not a chancre at all. The German terms chancre and initial sclerosis are preferable to chancreoid and chancre. Dr. Keyes very justly calls upon those claiming to prevent syphilis by excising the initial lesion for a trust-worthy history showing previous freedom from syphilis in such patients, added to confrontation. He modifies his previously expressed opinions as to the treatment of syphilis in that he would now make the tonic dose of the specific rather smaller and the course, in accordance with a rapidly growing judgment among observers, longer than formerly. He protests also against certain recent views in urethral pathology which would account for all ills of the genito-urinary passages by designating natural undulations as strictures, and would cure such ills by cutting said pseudo-strictures. We join heartily with the writer against the use of long-nozzled syringes in clap. They do as much harm as good. The ideal syringe is the one used in Vienna, figured upon page 49 of Bumstead and Taylor as "No. 3," formerly unattainable in America, now bearing (loc cit.) the stamp of G. Tiemann & Co. It is, an enlarged and improved form of the American "No. 0," and much superior to the "No. 1. A" figured by Keyes. Possibly "the Peerless Syringe" may prove itself a formidable rival. We note that Dr. Gouley receives the credit of the invention of the tunneled catheter. The book in general appearance is markedly superior to some other dermatological works recently issued by other publishing houses in the same city. The color of the covers is fast, unlike that of the drab and wine-tinted volumes often seen. The type is clear, typographical errors are few, and the paper is eminently respectable, being devoid of that parvenu gloss so trying to the eyes of the reader. E. W.

Student's Primer on the Urine. By J. TRAVIS WHITTAKER, M. D. Philadelphia: Presley Blakiston. 1880.

This is a very neat and concise little book, and the illustrations, which are etched by the author upon copper, are very good testimony to the claim which he makes of the suitability of the etching needle for delineation of microscopical appearances. The book is appropriately dedicated to Mr. Seymour Haden, known not more as a surgeon than as an aquafortist.

—The late Dr. Andrew Vans Dunlop, of Edinburgh, has left to the university of that city \$250,000.

Medical and Surgical Journal.

THURSDAY, MAY 13, 1880.

A Journal of Medicine, Surgery, and Allied Sciences, published weekly by Houghton, Mifflin and Company, Boston. Price, 15 cents a number; \$5 00 a year, including postage.

All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.

Remittances by mail should be sent by money-order, draft, or registered letter to Houghton, Mifflin and Company, Boston, Mass.

PRODUCTION OF SEX AT WILL.

We have had placed in our hands a series of letters upon the production of a desired sex, written to a scientific gentleman of this city, by Mr. D. D. Fiquet, of Houston, Texas, a graduate of the Harvard Law School, whose failing health drove him from the bar to a business in the open air, and who is at present a practical cattle-breeder.

In these letters Mr. Fiquet claims to have discovered a system by means of which, with unerring certainty, he can cause a cow to give birth either to a bull or a heifer calf, according to his wish. He developed his system at the cost of much previous experiment and many failures in his attempts "to discover the causes which control and the conditions which determine the matter of sex."

He made use of all available scientific authorities of note, discarding them one by one as he proved their fallacies. In this way he disposed of Thury's law, which, says Mr. Fiquet, "is utterly worthless in practice and wrong in theory. It is flatly contradicted by the ordinary experience of stock-raising."

Being impressed by Waldeyer's remark in his work on the ovum, namely, that for some time after impregnation the ovum is, in a certain sense, hermaphrodite, Mr. Fiquet was led to imagine that the matter of sex might perhaps be controlled and determined by the female during pregnancy. Familiar, also, with the fact that in the bee, moth, and butterfly families sex can be governed by the simple conditions of care and feeding, he resolved to try the effects of nutrition upon his cows after the act of coition. To this end he selected two animals whose condition for many months had been identical, and had them served by the bull. Having now two cows in precisely the same physical status, he fed one richly, and underfed the other. At term each cow produced a heifer. He then repeated the experiment with two other animals, treating them during their pregnancy in a similar manner. Each cow gave birth to a bull calf. Mr. Fiquet naturally abandoned this method, and, despairing of securing any aid through physiology, he "turned to nature herself."

An intimate acquaintance with the birth and death-rate statistics of life insurance had led him to remark the uniformity in the proportions of each sex. This suggested the thought that a harmless method of disturbing this uniformity of sexes at birth might be the solution of his problem. How to accomplish this was the next question.

Recalling to mind all his married acquaintance, he

made the observation, not only that in some families female children, in others male children, predominated, but likewise that a vigorous, passionate man and a cold, unimpassioned woman generally begat a surplus of female children, and that, reversing the temperaments, boys abounded. Then occurred to him the idea that if, by any means, he could render his bull more passionate than the cow at the time of coition he would thus secure the birth of the opposite sex, or heifers, and *vice versa*. Believing he could accomplish this by feeding and careful attention, he began his experiments.

Choosing eight cows, he fixed upon one from which he desired a bull calf,—the other seven were to produce heifers. Having carefully noted the dates of the periods of the eight cows, he allowed them to pass one oestrus, and thus was able to anticipate the return of the period in each. The cow destined to produce a bull calf came in first. Mr. Fiquet began to feed her most bountifully upon grain, corn, oats, meal, and rich hay. A few days before the reappearance of her period she was withdrawn from the herd, stabled, "and right royally attended." As anticipated, her passion came and in full blast. The bull, meanwhile, had been fed upon green and cooling food, which moderated the usual vigor of his passion, and the difference between the animals "was thus rendered plainly discernible."

"My theory," says Mr. Fiquet, "was that, the cow being far more desirous for the bull than was the latter for the cow, nature was calling more loudly through the female than through the male for the natural gratification of her desires; that the services of a male were more necessary than those of a female; and that, *pari passu*, the creation of a male thus became a more natural necessity than that of a female." This he supposed to be the desired disturbance of uniformity in nature, and consequently that in her very economy nature required the production of a bull calf. "Think of the theory as you may," he adds, "the cow was served by the bull twice, and the result was the desired bull calf."

The remaining seven cows were submitted to the gaultraity of a castrated bull, who, although impotent, served as a never-failing detective of the periods of the cows. Mr. Fiquet was thus enabled to anticipate their seasons of heat with exactitude, and, moreover, supposed the fruitless activity of this bull would be of use in reducing the passion of the cows.

Previous to his introduction to each of these cows, the other bull was generously fed on various rich grains and clover hay. On the other hand, the several cows were kept cool by light food,—grazing, green fodder, and bran. When their periods arrived, the animals were allowed to run temporarily with the castrated bull, and their frenzy was thus partially allayed. Being finally coupled with the service-bull, the conditions in each case were a rampant bull and a moderately excited cow,—the reverse of the conditions in the first experiment. The bull therefore being more anxious for the cow than the cow for the bull, Mr. Fiquet, for reasons already given, again predicted the birth of a calf whose sex would be the opposite of

that of the more passionate animal. The result was the birth of seven heifer calves. In all these instances, then, Mr. Fiquet was successful. Continuing his experiments, he bred from five other cows, the sex of the calf in every case being correctly predetermined. The cows of several of his neighbors were served by his bull, and, having inquired as to the previous treatment and feeding of the cows, and knowing the condition of his bull, Mr. Fiquet predicted the sex of the resulting calves with unvarying correctness. "My success," he says, "is therefore either unprecedented luck at guessing and the merest fortuitous accidents, or these experiments were based upon physiological truths."

He confesses to a lack of knowledge in the methods of horse-raising, but presumes his theories will hold good in the breeding of all uniparous animals, and believes his results can be reached by any careful, systematic breeder.

He feeds and prepares his bull for every special occasion, and does not allow him to serve more than one cow per week. If the bull be in course of preparation for a particular cow, he is never permitted to serve another which chances to come previously into season. An entire month is sometimes occupied in this preparation.

Mr. Fiquet's system will oblige the owners of large herds of cattle to keep several bulls, but the ease with which they can breed either sex at will (supposing the new theory to be true) will more than compensate for the increased expense, for the growth of their herds will be rapid.

Mr. Fiquet has never used excitants of any kind, relying solely upon a generous supply of rich foods. He expects to encounter incredulity on the part of cattle-raisers, and seems to desire avoidance of discussion. He simply presents his facts, the exactness of which is formally substantiated by certificates signed by trustworthy and well-known citizens of Housaton, and now in the hands of a gentleman of Boston.

Mr. Fiquet has already communicated details and results of his experiments to the *Journal of Agriculture*. In reply, a critic, without reason, we think, finds them a confirmation of Thury's law, namely, that when coition occurs in the early stages of the female's passion female offspring should be produced, the contrary if coition take place late in the period of the female. We fail to discover in what manner Mr. Fiquet's experiments prove the correctness of this theory.

The *Monthly Bulletin of the American Jersey Cattle Club* for July and August, 1879, briefly quotes the experience of Mr. Fiquet. The editor makes no direct comments, but foreshadows a shoulder-shrugging incredulity.

Having carefully read Mr. Fiquet's letters, our own impression is that he is a man of perfect sincerity. The modest manner in which he presents and details his experiments, his impersonal anxiety that practical cattle-raisers should be made familiar with his success, and the very evident absence of all wish on his part to win notoriety seem to be proved by his desire that some gentleman of scientific reputation, or some institution of influence, should call upon agriculturists

and cattle-breeders to try the experiments we have detailed.

If Mr. Fiquet be correct in his theories, and if the results he has obtained be more than mere coincidences, they will, it must be confessed, not only revolutionize cattle-raising, but add enormously to the wealth of the world.

SECOND ANNUAL REPORT OF THE CONNECTICUT BOARD OF HEALTH; SEVENTH ANNUAL REPORT OF THE BOARD OF HEALTH OF THE CITY OF NEW HAVEN.

THE second annual report of the State Board of Health of Connecticut fulfills the promise which the first report of last year led us to await. The number of correspondents of the board has steadily increased, and the zeal and interest in the work in like proportion; the registrars of the larger towns have been prompt in preparing their mortality returns, and in performing the duties assigned to them by the laws; the monthly mortality and sanitary reports have grown more and more comprehensive, and are attracting a wider circle of readers. A large number of copies of circulars on diphtheria and on the restoration of the drowned — the latter like the one issued by the State Board of Michigan — have been distributed.

The general health of the State is reported as having been for the most part satisfactory; malarial diseases have been decidedly prevalent, involving new territory at a pretty uniform rate. Malarial fevers in the Quinipiac Valley are discussed in the special reports, among which "typho-malarial" fever is given a prominent place.

There were quite a number of refugees in Connecticut from Memphis, and in several instances the advice of the board was asked in regard to effects which had been used in connection with yellow fever cases in 1878. The goods, as recommended, remained unpacked until the winter months, when they were disinfected and aerated.

According to the report, New Haven is the only port in this country that receives whole cargoes of rags. These come for the most part from Egypt, where the principal garment of a large part of the population is a long cotton robe, and hence the abundance of cotton rags. These rags are torn up and pressed into bales at Alexandria. The danger of the importation of the Oriental plague through these rags was suggested. The same danger has existed at various times within the last twenty years, though attention has not been generally called to it. The importing companies, the report says, were conferred with, and orders given that no further collections be made from infected regions, and the National Board issued an order for the disinfection of cargoes from infected ports. The rags are imported in closely pressed bales; consequently, the danger would be where the goods are unpacked at the paper mills. No cases of sickness could be discovered among the sailors on these vessels, either at sea or in port, and reports from the manufactories in the State show that no disease has

been communicated by rags, except small-pox in a few instances from domestic rags.

Plague is preëminently a disease of extreme poverty, and we believe the danger of an epidemic outbreak among our comparatively well-fed and well-housed people would be extremely small, even were the poison imported. It is now well known that the disease is to be found pretty constantly in a more or less active form in some parts of the Persian and Ottoman dominions.

Professor Hirsch, in the report of the German commissioners on the outbreak at Wetjanka, reports a very probable case of infection with plague from clothing which had been boxed up.

In speaking of "both typhoid and enteric fevers," in one passage of the report, the secretary seems to apply these names to distinct diseases, whereas they are ordinarily regarded as synonymous. We suppose he applies the term "enteric" to what Professor Clark, of New York, would call "cess-pool fever." In addition to the secretary's report, among other interesting papers is a short one on Sickness from Impure Ice; one on Sanitary and Unsanitary Conditions of the Soil, by Professor Lindsley, the efficient health officer of New Haven; a preliminary paper by the secretary of the board on school hygiene, a subject of great importance, which is sure to attract soon the attention it deserves; and a few words on the Pollution of Streams, by Prof. W. H. Brewer. In a report to the prison commissioners on the state-prison we notice a recommendation that the *insane* criminals be treated elsewhere than in the prison. Provisions for this step were lately made by the Massachusetts board, as was mentioned in our last issue.

Of the Seventh Annual Report of the Board of Health of the City of New Haven it is sufficient to say that the same spirit animates it which is reflected in the Report of the State Board, the president and health officer of the local board being both members of the State Board.

MEDICAL NOTES.

— Dr. James Sawyer, of Birmingham, writes as follows to the *Lancet* on the transverse depressions of the nails:—

"Many years ago Professor Sanders showed me these furrows in the Edinburgh Royal Infirmary, and I have been accustomed since to look for them in the patients who have come under my care. I agree with Dr. Duckworth that there is a rather more rapid formation of nail than that of two complete growths in a year. From my own observations I should say that from three to four months are usually occupied in the passage of a furrow from the lunula to the end of the nail. These grooves are very common. They are sometimes to be seen on all the finger-nails; often they occur only on the thumb-nails. If a person's nails be free from transverse furrows we may conclude, almost with absolute certainty, that he has not had a serious illness in the last three or four

months. I have found three or four of these depressions, equidistant and parallel, on the thumb-nails of women who are the subjects of dysmenorrhœa,—a furrow marking each painful 'period.'"

NEW YORK.

—The programme of the proceedings of the American Medical Association has not yet been definitely determined upon, nor is the list of papers to be read as yet complete; but the arrangements will probably be somewhat as follows: The sessions of the general association will be held in the large hall of the Young Men's Christian Association building, at the corner of Fifth Avenue and Twenty-Third Street; the delegates being seated on the floor, and spectators in the galleries. The different sections, whose sessions will be in the afternoons, will meet in other rooms in the Association building, and also in the lecture-rooms of the College of Physicians and Surgeons, across the street; the amphitheatre being assigned to the surgical section, in order that any demonstrations which may be given can be viewed to the best advantage.

The Association will be called to order at ten o'clock on Tuesday morning, June 1st, when an address of welcome will be delivered by Professor T. Gaillard Thomas, chairman of the committee of arrangements; after which the annual address will be given by the president, Professor Lewis A. Sayre.

In the section of Practice of Medicine, the first paper on Tuesday will be by Dr. William H. Thomson, of New York, on The Classification of Medicines. On Wednesday a paper on The Therapeutics of the Natural Waters will be read by Dr. W. C. Van Bibber, of Baltimore, and one on The Strong Galvanic Current in the Treatment of Sciatica, illustrated by Cases, by Dr. V. P. Gilvey, of New York. On Thursday Dr. Leonard W. Pitkin, of New York, will read one on Epilepsy.

In the section of Surgery, on Tuesday papers will be read by Dr. Benjamin Lee, of Philadelphia, on Spinal Extension, its Modes, Means, and Motives, and by Dr. George M. Beard, of New York, on Phimosia as a Cause of Nervous Symptoms, with Results of Operations. On Wednesday Dr. C. F. Stillman, of Plainfield, New Jersey, will read a paper on Newly Devised Orthopaedic Appliances, including the Seaton Splint, and Dr. James L. Little, of New York, one on Compound, Complicated Hare-Lip. On Thursday Dr. Henry G. Piffard, of New York, will make some Remarks on Lupus, illustrated by the Magic Lantern.

In the section of Obstetrics, on the first day a paper will be read by Dr. J. Marion Sims, on Battey's Operation in Epileptiform Affections; which will be followed by one entitled The True Import of Oophorectomy, or Spraying, for Reflex Symptoms, more particularly in Epilepsy and Catalepsy, by Dr. Montrose A. Pallen, of New York. On the second day Dr. T. Gaillard Thomas, of New York, will read a paper on Ablation of the Uterus, and Dr. William M. Polk, of New York, will read one on The So-Called Malaria of Puerperal Fever.

In the section of Ophthalmology and Otology (including Laryngology), on Tuesday, a paper on Stenosis of the Larynx will be read by Dr. W. H. Daly, of Pittsburgh, Penn., and one entitled Some Remarks on the Lesions of the Larynx in Pulmonary Phthisis, by Dr. Carl Seiler, of Philadelphia. On Wednesday, Dr. F. H. Bosworth, of New York, will read one on Bilateral Paralysis of the Abductor Muscles of the Larynx, and Dr. D. H. Goodwillie, of New York, one on The Surgical Treatment of Naso-Pharyngeal Catarrh. On Thursday a paper on The Therapeutic Value of the Galvano-Cantery in Diseases and Growths of the Nasal Pharynx will be read by Dr. W. H. Daly, of Pittsburgh.

In the section of State Medicine, a paper on the Death-Rate among the Rich and Poor, read by Dr. Drysdale, of London, will be read on the first day, and on the second day there will be papers by Dr. Joseph Jones, of New Orleans, on Hygiene and Fevers, and by Dr. E. C. Seguin, of New York, on The Psycho-Physiological Training of Idiotic Eyes.

The programme for the various public entertainments, as now determined upon, is as follows: On Tuesday evening the general reception tendered the Association by the profession in New York and their friends will be held at the Academy of Music. The parquet will be floored over, as for a ball, the music will be furnished by the Seventh Regiment band, and supper will be served by Delmonico, in Nilsson Hall adjoining. On Wednesday evening an entertainment, consisting either of a grand concert at Steinway or Chickering Hall, or of a performance at Booth's Theatre, with Edwin Booth as the principal attraction, will be given under the auspices of the committee of arrangements, the expense for which will be provided for by some of the large wholesale drug houses. On Thursday evening there will probably be a reception by Mayor Cooper at his private residence on Washington Square, at which the governor will be invited to be present; a reception at the Academy of Medicine, tendered by Professors Thomas and Barker; and receptions at Dr. Marion Sims's and other houses of medical men. On Friday, immediately upon the final adjournment of the Association, at one o'clock, the steamboat excursion provided by Mr. William Wood, the publisher, will take place, as previously announced in the JOURNAL. One feature of all the public entertainments, including that of Mr. Wood, will be that they will be conducted on a strictly temperance basis.

—At the last meeting of the Academy of Medicine, May 6th, Dr. George A. Peters read a memoir of the late Freeman J. Bumstead, which was followed by a paper by Dr. John H. Packard, of Philadelphia, on Some Important Advantages to be secured by Oblique Sections of the Skin in Surgical Operations. At the last meeting of the Academy of Sciences Professor George Macloskie, of Princeton College, read a paper on The Structure of the Vertebrate Skull.

—The bill providing for the establishment of a State Board of Health has been defeated in the New York Assembly.

—Mr. William Astor has just presented \$5000 to the building fund of the Manhattan Eye and Ear Hos-

pital, whose managers are now putting up a suitable building for the institution at the corner of Park Avenue and Forty-First Street.

PHILADELPHIA.

—In this city, where a whitewasher styles himself "Professor," where a colored barber is a "Tonsorial Artist," and every pill and corn-salve vendor is a "Doctor," it has been consistently held that one man's signature to a death certificate is just as good as another's. This plan, indeed, has worked after a fashion for many years; but, as may be supposed, not without coming occasionally in conflict with the good old coroner system, when some possible "quests" were lost forever. Recently the "crownor" has decidedly gained a point. In a case of death, where a colored herb-gatherer signed the certificate, the irate official looked over his spectacles, and read the "doctor" a good lecture. However, he did not stop here, but at his solicitation the board of health authorized its registrar to adopt the rule "to refuse to issue a permit for burial unless the physician who signs the certificate of death is known to be a regular graduate of a recognized medical school; or, if not so known, can exhibit a lawful diploma, qualifying him for the practice of medicine."

Miscellany.

THE DECENNIAL CONVENTION FOR REVISION OF THE PHARMACOPEIA.

MR. EDITOR.—The New England delegation to the sixth decennial convention at Washington for the revision of the Pharmacopœia consisted of Dr. Robert Amory, of Brookline, Mass., Prof. Edward S. Wood, of Harvard University, and Dr. Bennett F. Davenport, of Boston; Prof. George F. H. Markoe, of Massachusetts College of Pharmacy; Mr. Thomas Doliber and Mr. S. A. D. Sheppard, of Boston; Dr. H. M. Field, of Newton, Mass., delegate from Dartmouth College; Mr. A. L. Calder, of Providence, R. I.; and Dr. C. A. Lindsley, of New Haven, Conn., delegate from Yale Medical School.

The convention met at the National Medical College building in Washington, at noon on May 5th, and was called to order by Dr. J. E. Morgan, of Washington, the only surviving officer of the convention of 1870. Dr. Morgan was elected chairman, and Dr. D. Prentiss secretary, both *pro tem*. There soon ensued considerable discussion as to what associations were entitled to representation by their delegates, the call sent out by the officers of the last convention having called for delegates only from the incorporated state medical societies and the medical and pharmaceutical colleges; delegates from the United States army, navy, and marine service had also at the former conventions been always admitted. There were present also delegates from the Philadelphia County Medical Society, who claimed the right of being members of the convention, as it seemed to the delegates from most of the other States, unjustly; they justifying their claims by precedent, and on account of the report of work already done for the revision, which they were ready to lay before the convention. But the county societies in other States, who had likewise already done work

for the Pharmacopœia, had not understood that they were entitled to send delegates under the call. By a vote of the convention the delegation from the Philadelphia County Medical Society, however, were admitted, and Dr. L. B. Squibb, of Brooklyn, N. Y., was invited to take part in the deliberations.

On motion of Mr. Doliber, of Boston, a committee of nomination, consisting of one member from each of the delegations, was appointed to nominate the permanent officers of the convention. This committee reported the following, who were then elected by the convention: Dr. Robert Amory, of Brookline, Mass., president; Dr. S. C. Busey, of Washington, and Prof. P. W. Bedford, of New York city, vice-presidents; S. A. Castle, of New York city, secretary, and C. H. A. Kleinschmidt, of Georgetown, D. C., assistant secretary. The convention also voted that this same nominating committee should be a committee to propose a plan for the revision of the Pharmacopœia to the convention at its next day's session, and also to nominate a committee of at least twenty-five to see to the final revision and publication of the Pharmacopœia, according to the general instructions to be given them by the general convention.

Reports on the revision were received from the Suffolk County (Mass.) District Medical Society, Philadelphia County, National, District of Columbia, New York College of Pharmacy, Philadelphia College of Physicians, and other societies. A printed report from the American Pharmaceutical Association, prepared by Prof. Charles Rice, and a monograph by Dr. D. W. Prentiss, of Washington, D. C., were also presented.

Without transacting any other business of importance the convention adjourned at five p. m. until the next day.

The convention next day was called to order at twelve o'clock, but the committee on nominations not being ready to report, and it having transpired that they would not be able to do so until ten o'clock at night, the convention adjourned until that hour.

At ten o'clock the convention was again called to order in the National Medical College, and the committee on nominations, through its chairman, Dr. Judge, submitted their report, which was considered *seriatim*.

Committee on revision and publication of the Pharmacopœia: the president, Dr. Robert Amory; the secretary, Dr. F. A. Castle; Dr. Huntington, U. S. A., Dr. Gibbs, U. S. N., Professor Oldberg, United States Marine Hospital service, Professor P. N. Bedford, Professor C. L. Diehl, Professor Louis Dohme, Mr. Thomas Doliber, Dr. Lawrence Johnson, Dr. J. F. Judge, Professors J. M. Maisch and G. F. H. Markoe, Mr. H. B. Parsons, Professors H. G. Piffard, J. B. Remington, and Z. G. Wormley, Mr. Charles Rice, of New York, whom the committee chose as their chairman, Dr. W. S. W. Ruschenberger, Dr. E. R. Squibb, Professor A. B. Taylor, Mr. W. S. Thompson (D. C.), Professor O. A. Wall, Professor E. S. Wood, and Dr. T. F. Wood.

The recommendation in the printed report upon the revision of the Pharmacopœia by the American Pharmaceutical Association, as edited by Mr. Charles Rice, of New York, was reported favorably upon, a few alterations and additions having been made. This report directs that all the formulæ are to be in parts by weight, except that in the case of the fluid extracts parts by volume may be used if it seems best to the

committee of final revision so to direct. The contract for the printing is to be given to the publishing house offering the best terms.

The convention continued in session until two o'clock in the morning, when it adjourned *sine die*. The next decennial convention will be called by the committee on revision in March, 1881, and held in this city in May of the following year.

The only female delegate is Mrs. Dr. Clara Marshall, from the Woman's Medical College of Philadelphia. The committee on reception arranged for the delegates a visit to the Corcoran Art Gallery on Wednesday evening, a reception by President Hayes on Thursday, at five p. m., at the White House, and a reception at the National Observatory by Admiral and Mrs. Rodgers in the evening, and a trip by boat to Mount Vernon on Friday.

B. F. D.

WASHINGTON, May 7, 1880.

DR. HENRY CLARKE.

DR. HENRY CLARKE, of Worcester, died at his home on the morning of the 12th of April, of pneumonia, after an illness of only one week, at the age of fifty-five. He was well known to all the members of the profession in Central Massachusetts. For nearly thirty years he had devoted, with an untiring zeal, his whole life to the interests, advancement, and welfare of the profession. He chose it thoughtfully and conscientiously, he cultivated it assiduously, with a high sense of its great and important responsibilities; and to the last day of his life he strove, in spite of many discouragements, to honor and adorn it. Your readers will readily understand me when I say that Dr. Clarke was a model physician. His life and example any physician, old or young, could study with profit, and try to imitate. With broad, clear views of professional duty, he never allowed himself to be hampered within the narrow limits of a specialty. He took in the whole wide field, and gave his best days and his best powers to the study of disease, and its cure, in whatever line of the profession he found it. He was eminently a progressive physician. Always a diligent student, and an extensive reader, he kept pace with the rapid advancement of professional knowledge, and, as it were by intuition, seized upon what was valuable rather than what was new, and subjected it to the crucial trial of keen observant practice. His interest in his patients knew no bounds, and his industry was untiring. He knew that the relation of the sick to him was one of utmost confidence and dependence, and he never failed, in season and out of season, to do his whole duty to them.

Dr. Clarke was a brave and manly man. Throughout his whole professional life he struggled against sickness, fatigue, and overwork; yet he never faltered or complained. And when, in the judgment of his friends, he needed the care and the nursing rather than the patients, he bore up a brave, cheerful heart, never by word or look suggesting the thought that what he was doing for them required any sacrifice or self-denial in him.

A beautiful trait in the character of Dr. Clarke was the interest he took in the young men of his profession. They found in him a kind friend, a good adviser, and an efficient helper, through the struggles and discouragements of a commencing practice. He loved

to put business in their way. He loved to call upon them to assist him, making them feel that they could be of service to him. He always welcomed them to his house and to his generous hospitality.

To his professional confrères he was courteous, cordial, and helpful. He never allowed differences of opinion to mar the good fellowship and respect in which he held them, one and all. His character was pure and clean, open and fair to all the world. He was a good citizen, a kind neighbor, and a warm personal friend.

It is needless to add that such a man was successful. He stood in the very highest rank of the profession. He was honored, trusted, respected, and beloved by all, but by none more than by his patients, rich and poor alike. Their sorrow for his loss is as deep and true as is our own. To them and to us his place cannot be filled, for such friendships and such confidences are not the growth of days, but of many, many years.

RUFUS WOODWARD.

WORCESTER, May 3, 1880.

LETTER FROM BALTIMORE.

MR. EDITOR.—Baltimore, that is, professional Baltimore, received a surprise in January, from which it has not yet fully recovered, in the sudden appearance in our midst of a new medical journal, embracing the collateral sciences and dentistry. Its title was *The Practitioner: An Independent Journal of Medical, Surgical, Obstetrical, and Dental Science*; but the *London Practitioner* taking exception to this, the editor, Dr. Byrd, finally fixed the title as *The Independent Practitioner*. He is assisted by Dr. Wilkerson, who has charge of the dental department. The journal is very ably conducted, and already numbers among its contributors some of our most distinguished confrères. The introduction of dentistry is a great step forward, and the narrow prejudice that existed a few years ago against that science and art seems almost entirely to have disappeared. We should like to see the new journal embrace hygiene also, and enlarge the broad base upon which it has started. It is handsomely gotten up, published monthly, and no journal ever began under more favorable auspices.

Kakichi Mitsuuri, of Johns Hopkins University, has left for Beaufort, North Carolina, where is located the permanent sea-side zoölogical station of the university. C. B. Wilson goes next week, and later in the season Professor Martin, W. T. Sedgewick, E. M. Heartwell, and others. The steam launch goes down about May 10th.

We are still without our morgue in Baltimore, and although the question comes up at very long intervals in the council, yet no definite action has been reached. At present the station-houses are made to answer the purpose as occasion may require.

The ordinance to appropriate fifty thousand dollars for the insane asylum at Bay View was amended by Dr. Fiske that twenty thousand dollars be taken out of this year's levy, and thirty thousand dollars out of the levy of 1881. The amendment was adopted.

Since Dr. Jeffries woke us all up to the fact that color-blindness is very common, that a person can be so without knowing it, and that great danger to life and property may result therefrom, the subject has taken practical form. An examination of sight and

hearing of the employees of the Northern Central and Baltimore and Potomac railroads, similar to that just completed on the Pennsylvania road, has been commenced at the company's office by Dr. J. D. Thompson. The examination includes tests to discover short sight and color-blindness. The employee is required to tell correctly any given color at a stated distance, and for detecting short sight or imperfect hearing the usual experiments known to opticians and aurists are made. The examination will probably last several weeks, or until all the train crews, numbering some hundreds of men, are examined. A report will be made officially at the conclusion.

The State Board of Health under the new law has been appointed as follows: E. Lloyd Howard, C. W. Chancellor, and J. R. Ward, physicians; J. Crawford Neilson, civil engineer; C. J. M. Gwinn, attorney general; and James A. Stewart, health commissioner of Baltimore, *ex officio*. The act provides that the board shall consist of seven members, which includes a secretary, to be elected at the first meeting. It is understood that Dr. Chancellor will be elected secretary, the salary being eighteen hundred dollars a year, and the tenure of office during faithful discharge of duty; in this case the governor will appoint another member by and with the advice and consent of the senate.

The eighty-second annual convention of the Medical and Chirurgical Faculty of Maryland adjourned last week. It was largely attended. The principal addresses and papers were by Professors Chew (retiring president), Mallet, of Washington, Arnold, Tiffany, Miles, Chisholm, and others.

Dr. Samuel Theobald exhibited a bandage, invented by himself, that could be used as occasion might require for one eye or both eyes, or for wounds in which the inferior maxillary bone is to be supported. B.

LETTER FROM ST. LOUIS.

A CASE OF BATTEY'S OPERATION.

MR. EDITOR.—On April 29th Dr. Geo. J. Engelmann again performed Battey's operation. As it is still an operation seldom undertaken, a description of it may be interesting to the readers of the JOURNAL. The history of the case is as follows: The patient is a poor girl, and obliged to support herself by living out. Four years ago, at the age of twenty, she had a fall from a window, which resulted in no external injuries, but was followed by great pain in the region of the left ovary during menstruation, which gradually grew worse, till ultimately she was confined to her bed at these times; this condition made her so irregular in her work that she was no longer able to support herself, and the pain was so extreme that her health became greatly impaired. Various diagnoses had been made, and remedies used: at one time her trouble was hysteria; at another hernia, and, in accordance with the latter diagnosis, she had worn a truss; and there was some swelling and a great deal of tenderness in the neighborhood of the internal abdominal ring.

When she was sent by Dr. Thos. Holland to Dr. Engelmann for some ovarian trouble, he found that at the time of her menstruation there was a prolapse of the left ovary into the left iliac region, which accounted for her condition, and required the removal of

the ovary. A plain statement of the case having been made, the woman consented to the operation.

The primary incision began at a point two and a half inches below the umbilicus, and extended downwards in the linea alba about two and a half inches. At this time the pulse was 80; thirteen minutes afterwards, previous to opening the abdominal cavity (there had been some delay to stop the superficial hemorrhage), the pulse rose to 112.

Just before the peritoneal cavity was opened, Dr. P. V. Schenck, by putting his finger in the vagina, pressed the ovary forward, so that it presented, and was secured without any difficulty. The operation was performed four days after menstruation. The ovary was about one and a half times the normal size. It was seized firmly by forceps, and the mesovarium tied with braided silk ligatures. At the time of the ligation the pulse fell to 80. Sphygmographic tracings were taken all through the operation by Dr. G. Baumgarten, but they showed nothing peculiar. Eighteen minutes after the first incision was made, while the abdomen was still open, the pulse sank to 70, but afterwards rose steadily till the end of the operation, four minutes later, when it was 88.

The pedicle having been cut, it was, as soon as all hemorrhage stopped, returned to the abdominal cavity, and the wound united by three deep silver and three superficial annealed iron wire sutures. The silver sutures were fastened by flat shot. No styptics were used; the wound was dressed with antiseptic dressings of oiled silk, carbolized gauze, carbolized cotton, Mackintosh cloth, and ordinary cotton-wool. The operation was performed in a heated room, about 85° F., under the spray, and with all the usual antiseptic precautions. It lasted thirty-two minutes, and the abdominal cavity was open about twelve minutes. The incision in the peritoneum was about one and a half inches long. Chloroform was used solely. The patient was removed from the operating-room to a heated bed. The operation was performed in a private hospital, which has been open to patients only since January of this year. The result of the operation will be sent on as soon as it is determined.

The annual meeting of the Medical Association of Missouri will be held at Carthage in this State on the 18th, 19th, and 20th of May. This will be the twenty-third meeting of the association. P.

St. Louis, May 1, 1880.

NEW METHOD OF INTRA-UTERINE MEDICATION.

DR. ROBERT BATTY says: Eight years ago I was impressed with the opinion that the results obtained from intra-uterine medication by argentic nitrate and other escharotic remedies, as was then the custom in America, were very unsatisfactory. In my own practice it was a common observation that scanty menstruation of a permanent and intractable character followed upon the treatment, due apparently to a cicatricial condition of the endometrium left behind. In not a few cases stenosis of the os had to be remedied, and in some instances recurred time and again. In a few cases entire occlusion of the os occurred, and retained menses had to be evacuated.

In casting about for eligible substitutes, the iodine tincture and carbolic acid presented themselves, and

were successively tried, both separately and in combination, but the results thus obtained were meagre and unsatisfactory. Theoretically, iodine appeared to offer decided advantages, not only as a local stimulant to the uterus, but, in consequence of its ready absorption, as a local and general alterative also, but the official tincture proved too feeble in power to secure satisfactory results, and the strongest preparation of Dr. Churchill, of Dublin, was to me then unknown.

The thought of employing carbolic acid as a solvent for iodine suggested itself, and experiment developed a knowledge of the remarkable solubility of the latter in liquefied acid. At first, one drachm, then two, three, and four drachms of iodine was found to be soluble in an ounce of the acid. The last and strongest solution proved to be decidedly escharotic in its action upon the tissues, and especially upon heterologous growths of low vitality, and has been much used by the writer for attacking uterine cancer, and more particularly to supplement the curette. The standard solution employed in intra-uterine medication consists of one part by weight of iodine dissolved in four parts of liquefied carbolic acid, and to this solution I have given the name iodized phenol.

Iodized phenol is believed to be simply a concentrated solution of iodine in carbolic acid, and not in a proper sense a chemical compound. It is black in color, syrupy in consistency, and possesses in marked degree the pungent odor of iodine, which is rapidly given off when it is heated.

Since its introduction into my practice, the iodized phenol for intra-uterine medication has been employed by me to the almost entire exclusion of other remedies. In February, 1877, it was brought to the notice of the profession in America through the columns of the *American Practitioner*, and is to-day very much employed, but more especially in the Southern States. The recital of cases to illustrate its uses would be inconsistent with the brevity which should characterize the present writing, and hence it is proposed to present in general terms only the method of its application, and the results obtained from its use.

At first it was employed in a state of more or less dilution with glycerine, but, more recently, it has been used only in its full strength, being the energy of the application, regulated by the quantity employed and the extent to which it is carried into the uterine cavity.

The instrument employed in making the application may be one of the many forms of applicators, so-called, or any uterine probe or sound which will easily enter the canal. It is my habit, and I specially prefer, to use a rather slender and elastic hard india-rubber probe, made slightly tapering, and with a blunt, not bulbous, point. The elasticity of this probe allows it to yield rapidly to pressure, to change its course, to follow easily the canal of the cervix, and to enter the uterine cavity proper, and this in spite even of a moderate flexion or version of the uterus. From the cotton factory is obtained cotton-wool in the form of an untwisted rope or roll, the fibres of the cotton being perfectly straight, and lying parallel to each other. It is technically known to the cotton spinners as "the lap," and can be purchased of the best quality at our factories for eight pence to ten pence sterling per pound. It is admirably suited for gynecological uses.

Mode of Application.—Having selected six or eight of the elastic probes, I break off from the cotton "lap" four or five inches, and with my fingers separate or

split it into several fasciculi of such sizes as, when wound upon the probes, will enlarge them to the thickness desired. The end of a probe is now moistened slightly, and the fasciculus of cotton wound spirally upon it. The cotton-armed probe is now dipped into the iodized phenol, any redundancy is allowed to drip away, and the probe is passed into the uterus with a slow spiral movement as it advances. At first the probe is introduced but a short distance, and immediately withdrawn, and the case rests here to test the tolerance of the uterus for the remedy. At subsequent stages the probe may be carried to the fundus, and followed immediately by a second, and even by a third or fourth if well borne. The remainder of the wrapped probes are employed for wiping off the cervix or vaginal wall any of the phenol that may have touched these tissues. The energy of the application is regulated by the size of the wrapping, the depth to which the probe is passed, and the number of medicated probes used. When a very decided impression is to be made, a backward turn is given to the probe in its withdrawal, so as to leave the saturated cotton in the uterus, there to remain twenty-four hours, or even until it is spontaneously expelled. The application is renewed every four to fourteen days, according to the energy of the treatment.

I have abandoned the use of sponge tents in connection with the treatment set forth. When dilatation is required, the cotton-wrapped probe is employed, and the cotton left as a soft tent in the canal. The dilating power of this is notably less than of sponge, but nearly equal to sea-tangle, and it is believed entirely safe. The results are the following: (1.) A perfect removal of all cervical mucus, which is promptly coagulated, and comes away closely adhering to the cotton. The probes subsequently passed bring the remedy directly in contact with the diseased membrane. (2.) Always comparative, and usually entire, freedom from pain. This is a marked feature of the method, and in striking contrast with former experience. Carbolic acid is a local anæsthetic, and so numbs sensibility as to make the energetic application of iodine for the most part entirely devoid of pain. (3.) The iodine is so rapidly absorbed by the uterus that the patient remarks its metallic taste in the mouth and throat, ordinarily in five or ten minutes after the application. (4.) Softening and more or less dilatation of the cervix and os. (5.) There is temporary arrest of leucorrhœa, followed by (6) watery discharge, sometimes bloody. (7.) There is exfoliation of the superficial layer of the mucous membrane, which comes away in shreds, sometimes entire, and resembles glove-kid. (8.) Abrasions of the os promptly heal. (9.) Indurations of the uterus disappear. (10.) Leucorrhœa is permanently arrested. (11.) Villousities of the endometrium are removed without resort to the curette. (12.) Subinvolution of the uterus disappears. (13.) The menses become regular and healthy; menorrhagia and scanty menstruation, as well as dysmenorrhœa, are remedied. (14.) The appetite and digestion improve, and this, in many instances, without the use of medicines. (15.) So thoroughly is the system impregnated with iodine that alteratives by the stomach are not used. (16.) The form of the cervix and os is often completely changed; a large pulpy cervix, with patulous, slit-like os, becomes even virginal in type after long use of the remedy. (17.) Stenosis has not followed the treatment in any cases noted. (18.) Barrenness of nine

to fourteen years' duration has been removed in several instances.

Remarks.—Rapid, and at the same time satisfactory, cure of chronic uterine ailments, such as are contemplated in this paper, is not attainable by any method of treatment known to me. It is not proposed that rapid cures can be made by the means herein set forth; on the contrary, the long standing and obstinate cases, such as usually fall in my hands, require many months for satisfactory cure.

PRIZE ESSAYS.

CONCERNING the two-hundred-and-fifty-dollar prizes offered by the American Medical Association for essays on original investigations, Dr. Wood, of the *Philadelphia Medical Times*, writes, "It cannot fairly be gainsaid that in this country, whilst medical practitioners of the better sort are at least the peers of those of any other land, scientific medical inquiry is at a comparatively low ebb. When such leaders as Professor Flint occupy their attention with the writing of medical school-books,—the very primers of our art,—when there is not a single well-furnished physiological or pathological laboratory in the land at which active work goes on steadily, our pride in the present must be sustained by our hopes for the future. Original scientific talent is undoubtedly as abundant here as anywhere else in the world, but there is, unfortunately, a most severe dearth of encouragement. We hail, therefore, the proposed alterations in the by-laws of the American Medical Association as a step in the right direction, and as a public recognition of the need of encouragement. It is by no means sure, however, that the amendments, which propose that appropriate committees should select four subjects for investigation, and that four prizes of two hundred and fifty dollars each be offered for the best essays upon such subjects, are exactly what is wanted.

"To investigate a subject at the bidding of another is to take up a task in cold blood,—deliberately; whilst to investigate a subject because you are interested in it is usually to be drawn in, little by little, until eager desire turns work into play. The investigator who has original genius usually does best when, after proper training, that genius is left to select according to its own promptings. There are many prizes offered in this country upon determinate subjects, and very rarely do the essays elicited amount to much.

"Then, again, what is two hundred and fifty dollars as an encouragement to the original investigator? It is not enough to pay the expenses of any extended research in experimental medicine. Dr. S. Weir Mitchell's study of rattle-snake venom cost him over one thousand dollars, and the outlay upon another experimental memoir just completed in this city has amounted to nearly the same sum. If the American Medical Association desires to offer smaller prizes to encourage beginners or to stimulate older hands to dash off some brief essay, well and good; but what is wanted is the possibility of taking one prize which, by its magnitude, by the difficulty of obtaining it, and by the ceremonies surrounding its reception, shall be made so impressive as to make the man who has obtained it distinguished among his fellows. The competition for such a prize should not be with rival memoirs so much as with a standard of excellence so high as rarely to be achieved,

"The sum of money should not be less than one thousand dollars, along with a gold medal, to be a perpetual souvenir of the triumph. The successful candidate should be duly notified, and required to attend at the meeting of the association; and then, in full session, directly after the president's address, the prize should be awarded with appropriate ceremonies.

"The funds of the association are amply sufficient for this. Let there be one annual prize of two hundred dollars, or two biennial prizes of two hundred dollars each, to be given, if it is thought best, for some spe-

cially-directed research, and the grand prize to be awarded not oftener than once in two or three years, and only then when it is undoubtedly deserved. The greatest care should be exercised in selecting the committee of award, so that it should not be composed of those whose good nature should incline them to yield too easily a favorable decision. Rather let the committee feel that their mission is to keep unhalloved hands off the treasure, and only to yield it to him who has proved himself a very high-priest of scientific research."

REPORTED MORTALITY FOR THE WEEK ENDING MAY 1, 1880.

Cities.	Population estimated for July, 1879.	Reported Deaths in each.	Deaths under Five Years.	Percentage of total Deaths from				
				The Principal "Zymotic" Diseases.	Lung Diseases.	Diphtheria and Croup.	Scarlet Fever.	Typhoid Fever.

Seventeen Massachusetts towns.	130,010	60	16	20.00	11.67	15.00	—	—

One thousand nine hundred and seventy-seven deaths were reported; 716 under five years of age; principal "zymotic" diseases (small-pox, measles, diphtheria and croup, diarrheal diseases, whooping-cough, erysipelas, and fevers) 332, consumption 342, lung diseases 330, diphtheria and croup 115, scarlet fever 48, measles 44, diarrheal diseases 32, typhoid fever 28, whooping-cough 28, cerebro-spinal meningitis 13, malarial fevers 12, erysipelas 11, small-pox one. From *measles*, New York 18, Pittsburgh six, Cincinnati five, Philadelphia, Brooklyn, and Lawrence four, Baltimore, Lowell, and Holyoke one. From *whooping-cough*, New York eight, Baltimore, Boston, and Pittsburgh three, Brooklyn, Cincinnati, District of Columbia, and Nashville two, New Haven, Charleston, and Weymouth one. From *cerebro-spinal meningitis*, New York six, Philadelphia three, Baltimore, Chelsea, Holyoke, and Pittsfield one. From *malarial fevers*, New York eight, Brooklyn two, District of Columbia and Milwaukee one. From *erysipelas*, New York five, Philadelphia and Brooklyn two, Baltimore and Providence one. From *small-pox*, Philadelphia one.

Sixty-six cases of measles, 35 of scarlet fever, 22 of diphthe-

ria, and one of whooping-cough were reported in Brooklyn; diphtheria 22, scarlet fever 10, in Boston; diphtheria 22, scarlet fever three, in Milwaukee; scarlet fever 25, diphtheria 15, measles 12, cerebro-spinal meningitis three, typhoid fever one, in Providence; diphtheria two, scarlet fever two, in Cambridge; scarlet fever 17, diphtheria three, in New Bedford.

There being no reports from several large cities, namely, Chicago, St. Louis, New Orleans, Buffalo, Cleveland, the week's report for the country at large is of little value for comparison. Only one death is reported from small-pox, and that in Philadelphia. An increase of pneumonia, scarlatina, and measles—the last of a mild type—is reported from Providence.

In 34 cities and towns of Massachusetts, with an estimated population of 952,300 (population of the State being about 1,550,000), the total death-rate was 20.50 against 19.82 and 22.66 for the previous two weeks.

For the week ending April 10th, in 148 German cities and towns, with an estimated population of 7,701,350, the death-rate was 28.1 against 28.6 and 28.9 for the two previous weeks. Five thousand seven hundred and fifty-five deaths were reported;

1859 under five; pulmonary consumption 697, acute diseases of the respiratory organs 567, diphtheria and croup 135, typhoid fever 69, scarlet fever 64, whooping-cough 61, measles and *röteln* 48, puerperal fever 16, typhus fever (Braunschweig, six, Minden, Königsberg, Elling, Posen, Magdeburg, Thorn) 13, small-pox (Königsberg, Beuthen, Halberstadt, Mülheim) five. The death-rates ranged from 18.3 in Erfurt to 41.4 in Essen; Königsberg 36.3; Breslau 31.8; München 36.2; Dresden 23.9; Berlin 25.2; Leipzig 29.3; Hannover 25; Hannover 20.6; Bremen 28.2; Cologne 27.2; Frankfurt 22; Strassburg 30.2. For the same week, Vienna 35.7; Paris 30.8, — small-pox and diphtheria very prevalent.

For the week ending April 17th, in the 20 English cities, with an estimated population of 7,499,468, the death-rate was 22.7.

Three thousand two hundred and sixty-seven deaths were reported: acute diseases of the respiratory organs 348, whooping-cough 167, scarlet fever 107, measles 89, fever 33, diarrhoea 27, diphtheria 13, small-pox nine. The death-rates ranged from 16 in Portsmouth to 30 in Plymouth; London 21.6; Bristol 19.6; Birmingham 23.4; Liverpool 27.7; Manchester 26.7. In Edinburgh 28, Glasgow 24, Dublin 41. In the 20 chief towns in Switzerland, population 445,790, there were 48 deaths from acute diseases of the respiratory organs, diarrhoeal diseases 15, diphtheria and croup 10, scarlet fever five, whooping-cough four, typhoid fever three, small-pox one. Death-rate of Geneva 26.6; of Zurich 30; Basle 30.6; Berne 44.2.

The meteorological record for the week in Boston was as follows:—

Date.	Barom-eter.	Thermom-eter.			Relative Humidity.				Direction of Wind.			Velocity of Wind.			State of Weather. ¹			Rainfall.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U. S. ARMY, FROM MAY 1, 1880, TO MAY 7, 1880.

HEGER, A., major and surgeon. Assigned to duty as post surgeon at Fort Clark, Texas. S. O. 78, Department of Texas, April 24, 1880.

GOLDBARD, C. E., major and surgeon. When relieved by Assistant Surgeon Waters to comply with S. O. 74, C. S. A. G. O. in his case. S. O. 78, C. S. Department of Texas.

WATERS, W. E., captain and assistant surgeon. Relieved from duty at Fort Clark and assigned to duty at Fort McKavett, Texas. S. O. 78, C. S. Department of Texas.

WOOD, M. H., first lieutenant and assistant surgeon. Granted leave of absence for six months, and at expiration thereof to comply with paragraph 1, S. O. 74, C. S. A. G. O. S. O. 97, A. G. O., May 3, 1880.

GRAY, WILLIAM W., first lieutenant and assistant surgeon. Assigned to temporary duty at Fort Point, California. S. O. 55, Division of the Pacific, April 27, 1880.

MCCREERY, GEORGE, first lieutenant and assistant surgeon. Assigned to duty at Fort Apache, Arizona Territory, as post surgeon, relieving Assistant Surgeon Walter Reed, U. S. A. S. O. 48, Department of Arizona, April 16, 1880.

SCHUE, E. D., first lieutenant and assistant surgeon. Assigned to duty as post surgeon at Fort Grant, Arizona Territory. S. O. 48, C. S. Department of Arizona.

COCHRAN, J. J., first lieutenant and assistant surgeon. Assigned to duty at Fort Lewis, Colorado. S. O. 94, Department of the Missouri, April 28, 1880.

BOSTON SOCIETY FOR MEDICAL OBSERVATION.—A regular meeting will be held at the hall of the Medical Library Association, Monday, May 17th, at eight o'clock. Vote upon proposed change in Article VIII. of By-Laws.

A. T. CABOT, Secretary.

BOOKS AND PAMPHLETS RECEIVED.—First and Second Annual Report of the Central Sanitary Bureau of the Home Department of the Imperial Japanese Government. From July 1, 1875, to June 30, 1877.

Remarks on Rectal Feeding in Disease. By William Warren Potter, M. D. New York: Trow's Printing and Bookbinding Company. 1880.

Homeopathy: What is it? A Statement and Review of its Doctrines and Practice. By A. B. Palmer, A. M., M. D. Detroit: George S. Davis. 1880.

The Brain in Health and Disease. By Edward C. Mann, M. D. New York.

Periarthritis. A Study of Forty-Seven Cases.—Caries of the Ankle in Children. Results of Expectant Treatment of Thirty Cases. Two pamphlets by V. P. Gibney, A. M., M. D. New York: William Wood & Co.

Diseases of the Maxillary Sinus. By Edward Borek, M. D. St. Louis, Mo.

The Truth about Vaccination. By Ernest Hart. London: Smith, Elder & Co. 1880.

Ethyl Bromide. By Lawrence Wolff, M. D. (Reprinted from American Journal of Pharmacy.)

Old-School and New-School Therapeutics. By Frederick F. Moore, M. D. Alfred Mudge and Son, Printers.

Report of the Director of the Central Sanitary Bureau to H. E. the Minister of the Home Department, on Choleraic Dis cases in Japan during the Tenth Year of Meiji. 1877.

Surgical Diagnosis of Tumors. By Professor A. Lücke Strasburg. Translated by A. T. Cabot, M. D.

On the Treatment of Empyema by Resection of one or more Ribs. By William Thomas, M. B., London. Birmingham: Hall and English.

A Case of Spina Bifida. By John Ellis Blake, M. D. New York: William Wood & Co. 1880.

Twenty-Sixth Registration Report of Rhode Island for 1878.

A New Study of Cerebral Cortical Localization. The Effect of Willed Muscular Movements on the Temperature of the Head. Prize Essay of Alumni Association of the College of Physicians and Surgeons, New York. By R. W. Amidon, A. M., M. D.

First Annual Report of the Board of Health of the Taxing District of Shelby County (City of Memphis) for the Year 1879. By G. B. Thornton, M. D., President. Memphis. 1880.

The Cinchona Cure for Intemperance. By Charles W. Earle, M. D. Chicago: Bulletin Print.

Lectures.

I. A LECTURE ON INSANITY.¹

BY CHARLES F. FOLSOM, M. D.,

Lecturer on Hygiene and Mental Diseases in Harvard University.

BOILEAU said that all men are insane, the only difference between them being the varying degrees of skill with which they are able to conceal the "crack;" and in 1832 Haslam, perhaps the first expert in mental disease in England at that time, testified in court that he had never seen a sane man in his whole life, adding, "I presume the Deity is of sound mind, and he alone." It was only a few years after that time that Browne, the acknowledged leader of his branch of the medical profession in Scotland, stated in his lectures that a definition of insanity is an enigma which (Edipus could not have solved. We have, let us hope, advanced a step or two beyond this paradox. But before attempting to lay down a strict and modern definition, let us briefly discuss a few of the elements which are commonly considered as constituent of insanity: delusion, hallucination, inability of self-control, impulse, etc.

It should be observed that at the time when these seemingly hopeless views of any intelligent idea of the pathology of insanity were stated, an unsound mind was generally considered to be due to some disturbance of an immaterial soul rather than to a definite disease of a material brain; and therefore the explanation of the phenomena of insanity was thought to lie in the province of the metaphysician rather than of the trained medical man. Nevertheless, it can still be said to-day that it is impossible to give a thoroughly satisfactory definition of insanity, — to draw any hard and fast line, on one side of which we should put all the sane, and on the other all the insane. In well-marked cases, especially when attended with acute symptoms, no one could have any hesitation in settling, to his own satisfaction, the point of the sanity or insanity of any individual; but so long as the abnormal condition is to be described, not by physical signs, but chiefly by mental symptoms, by the effect on the power to think correctly and to act in accordance with logical thought, any one attempting to define insanity would experience the same difficulty which the older physicians found in the more common diseases before the splendid researches of John Hunter and Bichat made a diagnosis possible upon a physical basis.

It is not possible to divide sanity from insanity by a single criterion, such as the existence of delusions. A famous writer of the last century, whose writings will last many generations after the immense majority of his contemporaries are forgotten, was perfectly well able to perform the ordinary duties of life, and indeed was noted for the clearness of his intellect and the soundness of his reasoning; but he had the most extraordinary delusion that his posteriors were of glass, so that at times he did not dare to sit down, and he treated that part of his body with the greatest care so as to avoid smashing it. He recognized the character of his malady so well that he bequeathed a large part of his estate to founding an insane asylum, and indeed his delusion occasionally so interfered with his comfort that he was obliged several times to go to such an institution himself. In this case, the man was evidently insane, al-

though usually fully as capable of controlling himself, outside of his special delusion, as his fellows in society; and somewhat similar cases are by no means infrequent.

May we, then, define insanity as an abnormal condition of the mind, as a result of which some delusion exists?

The definition would not apply to Martin Luther, whose delusion that the devil appeared in his room to do him an injury was so clear that he threw an inkstand at his supposed form. If we examine closely we shall find that there is an important difference in the character of the two delusions. Dean Swift thought something true which was impossible both in the nature of things and from the circumstances of the case. In Martin Luther's time, a personal devil was fully believed in; indeed, according to the canons of the English church even much later than that, it was necessary to one's salvation to hold that Satan walked about the earth in personal form, doing all the mischief he could. Luther's delusion therefore consisted in thinking that something occurred which, in the belief of his time, might readily have happened; and he consequently was not in any sense insane. If a poor man thinks, contrary to the fact, that he has large sums of money in a particular bank, and bases his actions on that belief, he is clearly insane. Without being insane, however, he may have a delusion, very deleterious in its effect upon himself, that he is going to become rich by some fortunate chance or other; for such an event is not impossible, although in the individual case it might be exceedingly improbable, and such things do occur by the death of wealthy relatives and in other ways often enough to relieve the delusion from the appearance of utter impossibility, from the nature of things or from the circumstances of the case. Similar delusions of personal power, attractions, capabilities, injuries, insults, etc., are too common to need remark here.

I might illustrate this point still further by referring to hallucinations, properly speaking; that is to say, deceptions of the special senses. I was consulted not long ago with regard to the propriety of placing in an asylum a gentleman who had marked hallucinations of hearing, whereby he thought that he heard voices telling him that certain people were harming him. In this case the voices sounded as real to him as if they came from actual persons; but he knew that, as a fact, they were not real, and only due to some cerebral disturbance, which he recognized so fully as never to lose his control over them. He was perfectly able to attend to his business as a lawyer, and for a long time none of his friends knew that anything was the matter with him, with the exception of his wife, against whom, especially, the voices were directing his thoughts. The irritation had not got to be so great as to make me suppose at that time that he would be likely then to attack, or in any way injure, his wife or any one else; still it would have been but one step further for him to be driven on by the voices he heard to the actual commission of some crime, — a step often, indeed usually, taken in that class of cases, and it was necessary to consider him a dangerous man. In this case, the only deviation from health and strength in a man thoroughly strong and doing a great amount of mental work was the possession of a hallucination of hearing, and the immense majority of persons would have been utterly unable to detect his insanity, although he was a

¹ Delivered before the graduating class of the Harvard Medical School, and printed by request.

very decided lunatic, and, moreover, from the character of his delusions, unsafe to be at large as soon as they should become so marked that he could no longer control them. But we cannot describe insanity as the possession of a hallucination. Joan of Arc, for instance, had hallucinations of sight and hearing which led her to most heroic deeds, and indeed absolutely governed her whole life. But the delusion that holy spirits appeared to her and spoke to her and advised her, in answer to her prayers, to do what she did was simply an extravagant belief, fully in accord with the spirit and knowledge of the time in which she lived. Brierre de Boismont thinks that her hallucination was purely physiological, and in no sense pathological; it was not, among the peasants with whom she lived, contrary to possibility. Certainly the genius shown by an uneducated young peasant girl of seventeen in wisely directing the movements of great generals was no less extraordinary than her exaltation and personal influence over the common soldiers. It is difficult to judge of an event happening four centuries and a half ago and not exactly recorded at the time, but the hallucinations of Joan of Arc seem to me, like those of Saint Ignatius, Saint Theresa, and many others, to resemble the "miraculous appearance," a dozen years ago, which has resulted in the annual pilgrimages of thousands, for cure, to the Grotto of Lourdes in France, and to differ less from the religious ecstasy of Swedenborg and other devout believers than from insanity. Another class of hallucinations is represented by the famous case of Nicolai, the bookseller in Berlin, who had marked hallucinations of sight and hearing, commonly called visions, but recognized the unreal character of them, although an uneducated man, and paid almost no attention to them whatever. They appeared after some marked cerebral congestion, and were so far beyond his control that they came and went without the slightest power on his part to govern them; they were entirely removed by the application of leeches to the rectum.¹

We have seen, then, that neither a delusion nor a hallucination is necessarily a proof of insanity, and that neither term can be used absolutely in defining mental disease. To be characteristic of insanity the delusion must be impossible in the nature of things or under the circumstances of the case, as judged by the intellectual standard of the individual in question, or of the time in which he lived.

It is manifest that a delusion or hallucination must be estimated, so far as its seeming possibility is concerned, from the stand-point of the persons affected with the false belief. Otherwise we should be obliged to consider spiritualism and many other kindred false beliefs indications of insanity.

There is another class of cases, in which the definition of insanity is well-nigh impossible. I refer to the immense number of cases of mental weakness and of diminished power of self-control, of limited responsibility of different degrees; some alienists extend its province to cover nearly the whole criminal class, and others restrict its application very narrowly. One thing, however, can be said with certainty: that a crime, although it may be the first recognized act of an insane man, cannot alone be considered evidence of insanity. A man walking along the streets of London once seized

an axe, and violently attacked a passing hackney coach. For a long time the act was the only indication of an unsound mind, and it aroused suspicion of insanity, simply because it was so utterly without a motive and foreign to the man's usual character. Many months, indeed nearly a year, afterwards it was ascertained that the person was laboring under a delusion that he was Jesus Christ, and took that means of calling the attention of the whole world to the importance of his great mission. Another case in point is the Adventist Freeman,² who recently imitated the would-be sacrifice of Abraham under most striking and well-marked delusions; but which, unfortunately, were not detected in time to prevent his being sent to jail rather than to an insane asylum for treatment. It may be often a long time before such additional evidence is found, but some evidence more than a crime is needed to prove insanity. This would hardly fail to be discovered where the insanity is so prominent as to be a decided factor in the causation of crime, if sufficient time were allowed for investigation.

Of late years it has been more and more the custom of the courts to recognize this limited responsibility, — limited insanity, I am inclined to call it, for we certainly must include all these cases in our definition of insanity. The first case decided upon this theory of limited insanity, — if we may use the term, — so far as I can remember, was that of Kullmann, who attempted to assassinate Prince Bismarck. There was no real evidence of insanity. There was a hereditary predisposition to that disease, however, and Kullmann was shown to be of an inferior order of intellect, badly trained, and without definite and well-defined ideas of duty. He probably did not differ in these respects from a very large number of the criminal class, but the publicity of his act was the cause of his being examined by several experts, who decided that he was not fully responsible, although not technically insane, and he was therefore condemned to a moderate incarceration instead of the gallows. Two other extremely interesting cases came under my own observation quite lately: —

The first was a young girl from Ireland, left to her own resources at the age of fifteen, in domestic service in this State. She soon had a lover and an illegitimate child, — not so serious a fault in girls of her class in other countries as in the United States. She was sent to the work-house, where she remained until, at the death of her child, she was discharged some time before the expiration of her sentence for uniformly good behavior. Two years later she became pregnant again, and the evidence is, under promise of marriage. Her lover deserted her, and she worked from six o'clock in the morning till ten o'clock at night in a restaurant until the very morning of her confinement, when she was driven, at her request, to one of the lying-in charities. She remained there the usual period, was left alone twenty minutes after her discharge, and in that time smothered the infant under the bed clothes and fractured its skull with her fist. She concealed the body in her trunk, and went to her old employers, where she got work. The next day her employer came into the restaurant, as she thought, rather excited, although others in the room did not observe anything unusual in his appearance. She immediately accused herself, saying aloud, "I know what's the matter. I killed my baby, and he has found it." She was taken to jail, and remained four months to the time of the trial, when I first saw her. Her family history could not be ascertained. She was said by all who knew her at her last place of employment to be quiet, modest, and of good behavior. The physician in charge during her confinement saw nothing out of the way in her speech or deportment, and the officers of the prison made a similar statement. At the time of her being brought into court she fully appreciated the condition of things, had no delusions or hallucinations, and appeared of sound mind, except that she was of a low grade of intel-

¹ In allusion to this fact, Goethe makes Mephistopheles say: —

Und wenn Bluteleg sich an seinem Steiss ergötzen
Ist er von Geistern und von Geist curirt.

² Reported in full in the JOURNAL of March 18th.

lect, that she had no love for her child or regret for his death (as was the case from the first), and that she became very much excited beyond her control in speaking of her lover, who had abandoned her, threatening to kill him if he ever appeared again. There was a strong motive in killing the child to avoid its care or being sent again to the work-house, and there was no real evidence of insanity at the time I saw her; but there were some indications that she might have been insane, or at least not wholly responsible, when she committed the act, so that the court gave her the benefit of the doubt, on the ground of limited responsibility, as far as was thought justifiable, and she received only a short sentence. At the prison she behaved perfectly well until fully exasperated by some persons there, when she attacked them furiously; in confinement for punishment, she tore her own clothing, broke furniture, smashed windows, etc., utterly beyond any power of management, and sometimes apparently of her own self-control. She so resembled a maniac that she was sent in a strait-jacket to an insane asylum for observation, where, having nothing to disturb her, she has done perfectly well for a year and a half, except for a few breaches of the hospital discipline. She has performed very responsible work, even having the attendant's keys for many days at a time. In the year and a half there the only morbid indication has been that she once rushed purposeless to one of the attics, after chapel service, and seemed semi-conscious when overtaken by the attendant. When taken to her room, her eyes were staring, extremities cold, face very pale, and she remained in a condition resembling catalepsy for a few hours. She will probably be eventually discharged from the asylum and pardoned, as an analogous case to Kullman's.

The second was of a lad, illegitimate son of a highly educated Protestant of social position by a pretty Catholic maid. He ascertained his history when sixteen years old, until which time he had been kept in Catholic families or institutions, away from his mother. His inherited talent led him to books, from which he gained quite a considerable knowledge of good literature and a taste for it; and he also inherited a tendency to insanity, which showed itself in diminished power of control, morbid ideas of life, and utter despair at the want of employment, which would have affected a person of stable mind only uncomfortably, without driving him to desperation. He never used alcohol, tobacco, or even coffee, and was of exceptionally good habits. After vainly trying to get help from a relative, he happened to see in one of the papers a notice of the arrest of a man for sending a threatening letter. He was half fed, tired out, and ready to catch at anything suggested to his morbid mind, so that he sent to his relative a letter threatening to appear at his house and shoot him at a certain time unless help were given him to get work. No help came, and he appeared promptly by the appointed time, only to be arrested by the policeman who was waiting for him. By the very skillful presentation of his case on the part of his counsel he was set at liberty on bail without trial, as a case similar to Kullman's, and by good care has done well for more than a year, having recovered as healthy a tone of mind as is natural to him when perfectly well.

In all such cases the individual cannot be judged by any definite standard except his own condition at different times. If there is a decided change in character or action in a person, especially if the alteration is sudden and one which cannot be explained on ordinary grounds, it is always safe to be on the guard for insanity. If the change occur more than once the chance of insanity becomes almost a certainty. I am far from saying that all criminals, or even most criminals, are insane, although I must say that the more I see of both insane and criminals the harder it is to draw the line between them. If these points are kept in mind they may save you occasionally from making a mistake in obscure or at first unsuspected cases of insanity.

A very important point is always to consider every strange or unexplained action most carefully, whether deliberate or from impulse, particularly in the large class of eccentric, ill-balanced, weak-minded persons on the border line between sanity and insanity, at one time seeming to belong to the sane and at another to the insane class. Indeed, so far as responsibility for our actions is concerned, if we could measure nicely, we should be obliged to acknowledge that no two of us could be held to precisely the same degree of accountability.

I think that I have said enough on the difficulty of defining insanity, from the point of view of either the physician or the lawyer, without going further into the

consideration of uncontrollable impulse, imbecility, and other indications of special kinds of insanity, which can be more conveniently studied when we take up the individual forms of mental diseases. To proceed to definitions of insanity:—

Dr. Bucknill has defined insanity as "a disease of the brain (idiopathic or sympathetic) affecting the integrity of the mind, whether marked by intellectual or emotional disorder." He has since modified this definition by adding that the cerebro-mental disorder of insanity is such as to impair the healthy action of the will, thus making it apply to cases of simple deficiency of will or lack of self-control.

This definition covers nearly the whole ground, but there are certain cases where the abnormal action of the mind may be due simply to exaggeration of individual peculiarities, to some development of natural traits or eccentricities, properly speaking, rather than to disease.

Dr. Maudsley has perhaps surmounted this difficulty in his description of insanity, as follows:—

"Insanity is, in fact, disorder of brain, producing disorder of mind; or, to define its nature in greater detail, it is a disorder of the supreme nerve centres of the brain,—the special organs of mind,—producing derangement of thought, feeling, and action, together or separately, of such degree or kind as to incapacitate the individual for the relations of life. Mind may be defined physiologically as a general term, denoting the sum total of those functions of the brain which are known as thought, feeling, and will. By disorder of the mind is meant disorder of these functions."

You will notice another difference between the two definitions. Dr. Bucknill considers insanity a disease of the brain affecting the integrity of the mind. Dr. Maudsley wrote some years later, and indicated a step in advance when he recognized that there might be diseases of the brain affecting the integrity of the mind which cannot be called insanity, and he calls it a disorder of the mind of such a degree as to incapacitate one for the ordinary relations of life; that is to say, there may be certain deviations from the condition of sound mind, embracing very many shades of eccentricity and weak-mindedness, which do not constitute insanity.

Dr. Tuke's definition is almost equally satisfactory with Dr. Maudsley's, namely, that "insanity consists in morbid conditions of the brain, the result of defective formation or altered nutrition of its substance, induced by local or general morbid processes, and characterized especially by non-development, obliteration, impairment or perversion of one or more of its psychical functions." This is a definition which must be qualified by a reference to the general standard of belief (as in Luther's case); for instance, obliteration of compassion in a savage is not insanity.

Disorder of brain and morbid conditions of the brain are such general terms as to include all conditions, even those usually called reflex, giving rise to insanity; but the definitions also embrace too much, for they clearly include the delirium of starving, drunkenness, and of many of the acute febrile conditions, as well of the brain as of other organs. No one would be justified in calling the raving of brain fever or pneumonia or *mania a potu* insanity, but the conditions, as defined above, of irresponsibility exist.

These two definitions by Maudsley and by Tuke are the best which I have been able to find in the English

language, and yet it is easy to see their deficiencies. The fact is that insanity, instead of itself being a disease, properly speaking, is simply a symptom of diseases which, under varying manifestations, probably affect different portions of the brain,—at least they affect the brain in different ways.

Insanity, then, an anomalous action of some of the many functions of the brain, is a symptom of a whole group of diseases and disorders having their seat in the brain, or in some other organ in the body, and affecting the brain by reflex or sympathetic action.

Fifty years ago, the definition of Coleridge was largely accepted, even by physicians, that "madness is not simply a bodily disease." It is a sleep of the spirit. . . . When a man mistakes his thoughts for persons and things he is mad. A madman is so defined." Pinel, the great French reformer in the pathology and treatment of insanity, studied the metaphysicians Condillac, Montaigne, Locke, and Stewart more than the doctors and anatomists. But at the present time no one would pretend to deny that the brain is the organ of the mind, and that anomalous actions of the mind depend directly upon abnormal conditions of the brain, idiopathic, functional, or reflex.

THE COMPOUND SPHYGMOGRAPH.

BY A. T. KEYT, M. D., CINCINNATI, OHIO.

THE cut below represents my improved compound sphygmograph. The mechanism consists essentially of two sphygmographs of transmission and a chronograph combined in one apparatus, and all writing on the same smoked slide—the latter being regularly propelled by clock-work.

The sphygmographs are uniform and constructed as follows: The base for receiving the movements is an oblong receptacle, closed below by an elastic membrane and opening above into a transmission tube; the latter is of convenient length, usually twenty-four inches, and made up of alternate sections of glass and flexible tubing, and communicating by its opposite end with the vertical branch of a T passage. The horizontal branches of the T communicate each with a small chamber. Over one chamber is secured a graduated glass tube, over the other a delicate elastic disk. The cavities and passages are filled with *pure water*, and to provide for the expulsion of air from the disk chamber a small passage connects its upper part with the index chamber; a stop-cock opens and closes this passage. At the junction of the T is placed a three-way stop-cock, which according to its position directs the movements to the index tube or the disk. From the centre of the disk a pin arises, the point of which is lodged in a small hollow cone depending from the writing lever, and to which it is attached by a sliding clip. The lever is light,

six inches long, and its axis is pivoted to an adjustable plate. The pin socket is usually placed one half inch from the centre of the axis. The lever's point just lightly touches the recording surface. A reservoir with a depending ampulla and a stop-cock conveniently regulates the supply of liquid to the apparatus. The entire apparatus, except the bases, which are freely movable in any direction, is firmly secured to suitable supports.

The basal and disk membranes are each adjusted and maintained at a standard tension by means of a proper screw device; and the standard tension for each is determined by a definite and easily applied formula. By these means uniformity in the action of the membranes is secured.

The graduated glass tube serves as a diverticulum for the liquid displaced from the base as the latter is pressed down upon the organ of which the movements are to be observed; and at the same time the liquid column displays the movements to the eye, indicating their form, and measuring with precision their amplitude and the pressure at which they are best developed. Thus, the index tube is an interesting and indispensable part of the instrument. (It is placed erect when the instrument is in use, and turned down, for convenience, when it is not in use.)

The chronograph is essentially a watch provided with a mechanism for marking the divisions of time. It is a complete instrument, very convenient, and its record of seconds and fifths is entirely reliable.

Two sphygmographs are conjoined in one instrument, because the arrangement is quite convenient, and so extends the application that a single sphygmograph in

comparison with this combination appears of very small value.

This compound instrument answers all the purposes of any sphygmograph, and in addition is adapted to a great variety of physiological and clinical uses. It traces in a perfect manner the pulsation of the heart and different arteries, of the fontanelle, of tumors, the

movements of respiration, muscular contractions, etc. By means of the index tube it exhibits these movements to the eye; by means of the chronograph it shows their exact time relations; and by means of the double arrangement it traces two movements, as of the heart and an artery, simultaneously, showing their relations to each other and securing all the advantages of such a record. It is used with great facility, and executes the work with which it is charged with extreme fidelity.

For illustrations of work done by the instrument see *JOURNAL*, April 29, 1880.

RECENT PROGRESS IN PATHOLOGY AND PATHOLOGICAL ANATOMY.¹

BY E. G. CUTLER, M. D.

FATTY EMBOLISM.

M. WIENER² describes the results of experiments which he has performed under the direction of Professor Cohnheim. He finds that fatty embolism may take place from the lymph cavities; it was produced in the lungs as well as in the course of the systemic circulation by injection of olive oil, not only into the peritoneal and pleural cavities, but also into the subcutaneous tissue. The intervention of the lymphatic glands thus does not prevent the formation of fat embolism. It was only in cases where the embolism reached a very high degree that dangerous symptoms and death, arising from general pulmonary oedema, took place; the fatty embolism was usually unattended by any symptoms. In no case (unless there were complications) was a rise of temperature observed, and inflammatory changes in the embolized organs were never met with. The fat introduced into the circulation was removed by the urine, which often contained fat several days after injection into the lymph passages. The fatty matter was found almost always in the loops of the glomeruli, and in the other capillaries of the kidney; it was also seen in the lumen of the urinary tubules, so that the glomeruli appear to be the seat of excretion, which the author believes to take place by a process of filtration.

INVESTIGATIONS CONCERNING FATTY EMBOLISM.

J. Scriba publishes³ a series of experiments performed on frogs. Fat when injected into the veins and into the lymph sacs or peritoneal cavity entered the circulation very quickly; in the stretched out tongue it was determined that the first drops of fat appeared in the lingual vessels forty-two seconds after the tibia of the frog had been broken. Fat was found regularly in the urine of the frogs, singularly enough in periods between which were times when the urine was free from fat. After ligation of the renal artery (by which it is well known that the flow of blood to the glomeruli is cut off, while the urine continues to be secreted through the medium of the vena renalis) there was no longer any secretion of fat by that kidney; the separation of fat must therefore take place in the Malpighian body.

Also in man there is an abundant and singular periodical separation of fat by the urine when it has got into the circulation. The first period of excretion of

fat lasted from two to four days after the disease or injury which caused the fat to appear in the urine (fractures, operations on bone, osteomyelitis); then it again occurred after a pause of several days, usually from ten to thirteen days; and either finally ceased, or came in intervals of from six to ten days for a third or even fourth time. The fat is rarely present in the urine in the form of free drops, only when it is secreted in very large amount; it is usually emulsified in the very finest drops. Besides the kidneys the spleen appears to be the only organ in which the fat found in the circulation escapes through the capillary wall; and here small fat drops are seen in the interior of the pulp cells.

With regard to the action of fat in the circulating blood, the author holds that it is not so unimportant as it has usually been considered. Even on agitating the blood with oil in a glass a destruction of red blood corpuscles occurs with freeing of hæmoglobin. In accordance with this, there was found in the blood serum of animals, in which large quantities of oil had been injected into the veins, dissolved hæmoglobin, and once also hæmoglobin in the urine, while at another time there was an abundance of biliary coloring matter in the urine.

This explains the presence of brown casts found by Riedel in the urine of patients who had suffered from fracture. The (partial) destruction of red blood corpuscles in fat embolism is probably to be referred chiefly to the mechanical, and perhaps also to the chemical, effect of the fat drops.

What, then, causes death in fat embolism? At all events, very great quantities of fat are required; hæmorrhagic infarctions occur in the lungs in very widespread fat embolism; meanwhile, before the pulmonary vessels are so completely stopped by the fat as to cause deficiency of breath, much fat has already gone over into the arterial system, and then severe symptoms or even death may result from extensive embolism of the vessels of the central nervous system. The temperature of the body in pure fat embolism is always a little diminished; accordingly, fat embolism does not give rise to fever.

THE SPINAL CORD IN TETANUS.

Mr. Alban Doran and Dr. Vincent Harris⁴ showed before the Pathological Society of London several microscopical specimens of a spinal cord from a fatal case of tetanus occurring after ovariectomy, in which the disease had apparently arisen from a cold draught. The tetanic symptoms were well marked, and caused death from asphyxia. The stump of the pedicle was found to be in every way healthy. After careful examination they had failed to detect disintegration of the gray cornua described by Lockhart Clarke, but they had seen one or two of the isolated transparent, unstained patches described by Dickinson, Coates, and others. These patches were also seen in another cord from a case of tetanus that they had examined. In addition, they had noted proliferation of the small neuroglia nuclei beneath the epithelium of the central canal in the lumbar region; in the cervical region a band of exudation was seen passing quite across this canal, and there were evident signs of exudation in the cervico-dorsal region. They had not found a shrinking of the stellate cells of the gray matter.

SOURCE OF ALBUMEN IN ALBUMINURIA.

Litten¹ gives the results of some interesting experiments which he performed to determine the point where albumen escapes into the urinary tubules in cases of albuminuria. He followed the methods previously adopted by Posen and Ribbert. Posen's method consisted in fixing the albumen in the place of its origin by the boiling heat; while Ribbert fixed the transuded albumen, not by means of heat, but by placing the fresh tissue in concentrated alcohol. Litten, using both of these methods, first proved that in the normal rabbit's kidney under physiological conditions there was no transudation of albumen into Bowman's capsules surrounding the Malpighian bodies. He then instituted the following experiments:—

(1.) He tied the renal vein for two hours.

(2.) He tied the renal artery for two hours.

(3.) He tied the renal artery temporarily for an hour and a half to two hours. The animals in the first two sets of experiments were killed directly. In the last they were allowed to live a quarter to half an hour after the ligature was removed. In the first series of cases there was considerable albumen found between the glomerulus and the capsule, which in favorable sections could be followed into the convoluted tubules. In most cases the glomeruli were surrounded by the transudation; in others it was only in the part of the capsule towards the convoluted tubule. The transudation was usually finely granular and colorless, though sometimes it had a reddish tint from admixture with blood. Sometimes a layer of blood appeared between the capsule and glomerulus. The Malpighian body appeared always intact, not compressed, its nuclei preserved and capable of receiving staining fluid. The nuclei of the epithelium of the tubules were everywhere perfectly retained, and readily received coloring matters.

In the second series of cases the structure of the kidneys was intact everywhere. The albuminous mass described above was found in places, though in much less extent, and frequently it was only just recognizable.

The changes in the last set were much more intense. The space between the capsule and the Malpighian body was full of the albuminous mass already described, and it could be followed to a long distance in the tubules. Though chiefly in the tubules of the cortex, it was also found in the collecting tubules of the pyramids. The epithelium of the capsules was much swollen and disquamated, and was mixed with the transudation. The nuclei of the epithelium of the convoluted tubules were for the most part perfectly preserved; sometimes the cells had become smaller and were crumbled, and in some preparations they could not be colored in places. The three observers, Posen, Ribbert, and Litten, therefore conclude that in mammals the glomeruli must be regarded as the part of the kidney from which the albumen comes. Posen found albuminuria and so forth after ligation of the ureter, and, considering all the conditions, Litten thinks that the capsule exudation and albuminuria occur under circumstances which have this in common,—a transient increase in the diameter of the renal vessels (naturally the capillaries of the glomeruli here are the ones which are especially taken into account). In cases of passive congestion (ligature of the

vein, ureter, and so forth) the dilatation of the vessels is evident. In cases of transient ligation of the artery it may be explained as follows: the irritation of the ligature causes a very considerable contraction of the vessels, and after removal of the ligature they suffer a transient dilatation; that it is transient is shown by the fact that the albuminuria is of short duration, and may disappear in twenty-four hours. Microscopic examination here shows the glomeruli are frequently separated from the capsule by a small space, in which no exudation can be found. That it has not been absorbed is evident from the fact that the masses may be found in parts of the tubules nearer the ureter. After a few days these spaces between the glomerulus and capsule are no longer to be discovered.

This assumption, that temporary dilatation of the vessels may lead to transitory albuminuria, is supported by a series of experiments made on strychninized animals. Diuresis began after remission of the vascular spasm, and it was constantly found that immediately after the cessation of the spasm urine was excreted, at first highly albuminous, but later becoming less so, and at the end of an hour being quite free from it; the blood pressure at the time of the action of the strychnine being very high, and during the albuminuria extremely low. A microscopic examination of the kidneys showed that during the stage of spasm (that is, during anuria) the Bowman capsules were empty, while after commencement of the albuminuria the transudation into the capsules was found. This fact coincides with Wittich's experience (confirmed by Stokvis) that section of the vaso-motor nerves caused albuminuria, while section of the secretory nerves did not produce it. Moreover, the albuminuria which Schiff, Claude Bernard, Longet, and others caused by injury to certain parts of the brain, especially the vaso-motor centre, belongs here; so, too, the albuminuria following *commotio cerebri*; and perhaps also that which appears temporarily during high temperatures. The single principle which seems to underlie these apparently so different cases of albuminuria is a disturbance in the circulation of the kidney, which allows a dilatation of the vessels and a consequent retardation of the stream of blood. Litten considers that his experiments have shown that the passage of albumen into the tubules, and hence into the urine, is less dependent on blood pressure than has been previously believed. Albumen is seen to occur in increased pressure (ligature of the renal vein or ureter); in *unaltered*, or at least in relation to the normal *certainly not increased, blood pressure* (after removal of the temporary ligature of the artery); and lastly in diminished pressure (section of the renal nerves and strychnine poisoning in the stage after termination of the vascular spasm).

— The *British Medical Journal* says that the Belgium Royal Society of Public Medicine is organizing a general congress of public hygiene and medicine, to be held in Brussels next August. Of the questions to be discussed the most important ones are on the adulterations of food, contagious diseases, the causes of insubility, and the hygiene of primary schools.

— Dr. Chisholm, in the *Ohio Medical Recorder*, advocates the substitution of the bromide of potassium for the sulphate in Dover's powder, and states that the efficiency of the powder is greatly increased by the substitution. — *Chicago Medical Gazette*.

Hospital Practice and Clinical Memoranda.

BOSTON LYING-IN HOSPITAL.

SERVICE OF DR. W. L. RICHARDSON.

[REPORTED BY C. P. STRONG, HOUSE PHYSICIAN.]

PUERPERAL SEPTICÆMIA.

CASE I. A. W., primipara, aged thirty-nine, entered the hospital November 22, 1878, stating that the waters had escaped during the previous night. She had had no pains nor flowing until two hours before her entrance, when quite a brisk hæmorrhage began, which continued for some little time after she was put to bed. She had been drinking, and was very nervous. Palpation showed the breech behind the pubes. The fetal heart was heard. By vaginal examination the cord was felt hanging out through the vulva, cold and pulseless. The os was dilated to the size of a twenty-cent piece, thin and soft. Ether was given, and the os manually dilated until the hand could be passed into the uterus and podalic version performed, with forceps to the after-coming head. The uterus contracted firmly with very slight hæmorrhage, and the patient rallied well from the ether. The child had evidently been dead some time, as the skin was desquamating, and the odor was very offensive. The placenta was also partially putrid. Ergot and strong carbolic douches were ordered.

The urine just before delivery contained one fourth per cent. of albumen.

November 23d, first day. At the morning visit the patient was very nervous, and chloral and bromide potassium were ordered. The lochia were offensive. Pulse 76; temperature 99.2° F. Evening visit: Pulse 90; temperature 101.6° F. There was no albumen in the urine. November 24th, second day. Morning visit: Abdomen a little tender. Pulse 76; temperature 98.6° F. Evening visit: Pulse 66; temperature 102° F. Quinine was given, two grains every four hours. November 25th, third day. Morning visit: Lochia not offensive. Pulse 84; temperature 100.2° F. Evening visit: Pulse 76; temperature 100° F. November 26th, fourth day. Morning visit: Pulse 72; temperature 99.2° F. Evening visit: Pulse 72; temperature 99° F. Quinine stopped. November 27th, fifth day. There was no abdominal pain or tenderness, and both pulse and temperature were normal.

From this date, although the pulse averaged about 96, the temperature never reached 100° F. until the evening of the ninth day, December 1st, when it was 100.5° F. The patient always said she felt nicely, and, except her nervous manner, appeared all right. During the night of the ninth day she got out of bed, and wandered about the ward, but at the morning visit of the tenth day she had no recollection of the fact, but said that she had passed one of the best nights since her confinement.

December 2d, tenth day. Morning visit: Pulse 104; temperature 99.4° F. Evening visit: Pulse 120; temperature 100.2° F. December 3d, eleventh day. Morning visit: Pulse 106; temperature 102.4° F. Evening visit: Respirations 56; pulse 140; temperature 104.8° F. She continually muttered to herself, and was wandering and stupid. She would, however, answer if spoken to loudly. There was considerable thick mucus in the mouth, and the teeth were covered

with sordes. She passed her urine in the bed. A slight cough was noticed, with dullness over the lower right back and fine râles. Coarse râles were heard over both backs.

December 4th, twelfth day. Morning visit: Respirations 45; pulse 144; temperature 103° F. Evening visit: Respirations 45; pulse 140; temperature 103° F. Her condition was about the same; still she took her food well. The catheter was required. December 5th, thirteenth day. Morning visit: Respirations 12; pulse 135; temperature 102.8° F. (axilla). Evening visit: Respirations 56; pulse 120; temperature 104.6° F. (vagina). At eight p. m.: Pulse 200; respirations 60. She slept some during the first part of the preceding night, but was very restless during the latter part. She became decidedly weaker during the afternoon, taking food with difficulty, and in the evening came a marked change for the worse. Nourishment was taken only by the teaspoonful, and the patient could not be roused from her stupor.

December 6th, fourteenth day. Morning visit: Respirations 61; pulse 175; temperature 105.7° F. (vagina). She was now rapidly sinking. The lochia were offensive for the first time since the third day. She was unable to swallow, and died at one p. m.

Autopsy by Dr. R. H. Fitz. *Pia mater* thickened, opaque, and œdematous. Cerebral substance unusually injected. *Lungs*. Old adhesions to thoracic walls. Lower surface of lower lobe of right lung covered with recent false membrane. Lower lobes of both lungs moderately infiltrated with dark-red matter. On pressure, opaque grayish-red fluid escaped. Occasional patches of purulent infiltration. At apex of lower lobe was a dilated bronchus leading to a cheesy nodule, the size of an almond. *Spleen* about twice the normal length; soft. Pulp grumous. *Kidneys*. Cloudy swelling. *Liver* normal save for several dense yellow nodules, large as grape-seeds, inclosed in a capsule. *Uterus* slightly larger than closed fist. Left Fallopian tube, ovary, and broad ligament adherent. Recent ecchymosis in Douglas's fossa on the left. On posterior wall of bladder, on left also, by uterus, was a nodule of blood clot, as large as a raisin. Recent ecchymoses on mucous membrane of left posterior wall of bladder. *Vagina* and *interior of uterus* smeared with an opaque, reddish-gray fluid, of creamy consistency. Placental insertion on the left corner of uterus. On posterior wall of uterus, near fundus, also near internal os, the surface was shreddy. On left of external os was extensive laceration extending into vagina, triangular, base looking towards vagina. Base one inch long by three fourths inch wide. Veins contained recent clots or were empty. No evidence of œdema of pelvic connective tissue.

Diagnosis. Thickening of arachnoid and œdema of pia mater and brain substance. Acute broncho-pneumonia and œdema of lung. Acute pleurisy. Bronchiectasis. Chronic broncho-pneumonia. Acute hyperplasia of spleen. Cloudy swelling of kidneys and liver. Acute endometritis. Laceration of cervix.

PUERPERAL MANIA.

CASE II. M. D., primipara, aged fifteen years. The day after a journey of several hundred miles in the cars, the patient was brought into the hospital October 12, 1878, with the history of pains for twelve hours, and escape of the waters. Examination showed that the os was fully dilated, and the head almost on the

perineum. In an hour after entrance the labor was terminated normally.

Previous to the delivery the patient's actions were so strange as to attract attention. She tossed from one side of the bed to the other, rapidly shaking her head from side to side, executing every movement with sudden violence, and this in the intervals between the pains; during a pain she screamed incessantly. Her answers to questions came reluctantly, and only after persistent repetition. Her pupils were widely dilated. The urine was normal, containing no albumen. During the first three days of her lying in these symptoms continued the same, with pulse and temperature about normal, but on the morning of the fourth day the pulse was 132, temperature 104.6° F., and patient very nervous and sullen, absolutely refusing to speak to any one. She had cried all the previous night, without any assignable cause. During the afternoon her temperature rose to 106° F., accompanied by very dry skin and great restlessness, but diaphoretics and cathartics reduced this to 101.8° F. the following morning. Up to this time, although she manifested no particular affection for her child, she had always treated it kindly, but now she commenced to abuse it by pinching, sticking in pins, etc., and it was necessary to remove it from her bed, allowing her, however, to nurse it at intervals to relieve her breasts, which were very full. Her evening pulse and temperature were the same as the morning. During the night she was discovered by the nurse turning somersaults in the bed and walking about the ward, but in the morning she refused to give any explanation of her actions or to answer any questions whatever, exchanging her nervous manner for sullen obstinacy. At the visit her pulse was 114; temperature 104.6° F. Isolation and the constant presence of a nurse prevented any further violent actions upon the patient's part; sleeplessness was overcome by hypnotics, and from this time there was progressive improvement, noticeable from day to day, in the patient's manner, so rapid that in five days she was perfectly sane, wished to have her child with her, and ate and slept well. There was no return to her previous condition, and three weeks after leaving the hospital she was perfectly well and attending school.

At no time during her lying in were the lochia offensive, nor was there any abdominal tenderness.

POST-HEMIPLEGIC MOBILE SPASM.

CASE III. A. F., primipara, aged twenty-six. Entered the hospital November 3, 1878, and was delivered after a perfectly normal labor. At the time it was noticed that her right arm was smaller than the left, and kept constantly flexed, and that the right leg was also flexed, with the foot turned in, somewhat like talipes varus. The first ten days of her convalescence were passed normally, except that both pulse and temperature ran somewhat higher than usual without any apparent cause. Upon the eleventh day she complained of inability to sleep the preceding night on account of the violent twitching of the right arm and the consequent pain. She was lying on her right side, with the right arm beneath her, and the wrist held firmly by the left hand to control the movements. She was groaning and tossing about, evidently quite hysterical. Chloral and bromide given in large doses produced but temporary relief. The next day the twitchings were much worse; it was impossible to hold the right arm ex-

tended. Pain was so severe in the affected shoulder and arm that large doses of morphia were required, under which she slept most of the night, but moaned incessantly, although the movements were much less marked while she was asleep. Her temperature rose to 104.6° F. On this day she was seen by Dr. James J. Putnam in consultation, who reported:—

"The condition has existed since infancy, when the right side was injured by a fall, but more markedly since confinement. All the muscles of the right shoulder, arm, leg, and face are the seat of constantly recurring mobile spasm. Face: the zygomatics are principally involved. Arm: all the muscles involved, but the habitual position is flexion at the elbow and wrist. Fingers: bird-claw position, except the index finger, which is frequently extended. Thumb: all the muscles at the base are strongly contracted, but the last phalanx is extended. Foot: in the position of counter-flexion. Toes: bird-claw position.

"All the movements are greatly intensified with voluntary effort. The right arm is warmer than the left, smaller, and three fourths of an inch shorter from olecranon to inferior condyle. No movements of trunk muscles are seen, perhaps because the patient is lying in bed. On the right side of the trunk there is an eruption, but none on the extremities."

Her condition was the same on the succeeding day, and morphia was required for sleep, but there was considerable improvement during the next two days. The day after, however, the movements returned, and were as severe as at any previous time, her temperature rising to 105° F. This was the last marked attack, yet she always held the right wrist in the left hand to keep the arm quiet.

When she left the hospital she could not use the right arm, but could control, to a considerable extent, the involuntary movements. She walked in a sidling manner, trailing the affected leg after her, never putting it in advance of the other.

GANGRENOUS VAGINITIS.

CASE IV. M. C., aged twenty-three, last catamenia in July, was sent to the hospital April 16th, three p. m. Reported as being in labor three days. Palpation. Tumor presented the long diameter transverse. No fetal heart could be heard. Per vaginam the head was on the perineum, presenting O. L. P. There was a putrid, extremely offensive discharge from the vagina of greenish-yellow matter. Two quarts of urine were drawn. At 4.30 p. m., Dr. Richardson delivered with forceps a child weighing eight and a quarter pounds, face to pubes. The child gasped several times, but respiration could not be established. The placenta was removed manually, and found to be fatty degenerated, decomposed, and putrid. Uterus remained flabby and soft. Ether subcutaneously and a cold intra-uterine douche effected firm contraction. Pulse 120. Perineum intact.

April 17th. Pulse 90; temperature 98.4° F.; passed a comfortable night. The lochia were offensive, and there was some tenderness over the uterus. The whole surface of the vulva on the inside, extending up the vagina, was covered with green gangrenous ulcerative patches with well-defined borders. Strong douches of carbolic acid were applied every two hours, and tampons saturated in carbolic oil; uterine douches were given three times daily. Pulse 90; temperature 99.6° F.

April 18th. Pulse 94; temperature 100.4° F. From this date to the 26th the patient gradually convalesced. The ulceration about the vulva improved steadily, so that on the 25th, examination through a speculum showed only a few small spots which had not healed. Tampons saturated with tincture of myrrh were applied to these. Vaginal douches were continued every four hours, the lochia being still somewhat offensive.

April 27th. Pulse 92; temperature 104.2° F. Was interviewed by state agent, and felt worried about their questions. Temperature 102° F.; pulse 96. April 28th. Pulse 96; temperature 100.8° F. Evening: pulse 90; temperature 100.4° F. Has felt perfectly well all day; lochia not offensive. April 29th. Pulse 104; temperature 104.2° F. Slept well all night; crying all the forenoon because she can't sit up; no appetite; tongue furred; lochia suppressed; hot douches given frequently, and poultice applied to abdomen. Pulse 98; temperature 102.4° F. April 30th. Pulse 90; temperature 101.8° F. Lochia are normal in amount, but still some offensive; ulcerations have entirely disappeared. Patient has been ugly and notional throughout her sickness, and is continually worrying. May 2d. Patient sat up; still considerable lochial discharge. May 5th. Uterus measured four and one half inches; there was a profuse catarrhal discharge slightly tinged with blood; position of uterus normal; no ulceration visible. May 6th. Discharged well.

INSANITY; SUPPOSED PREGNANCY.

CASE V. H. S., widow, aged fifty-seven. At the age of twenty the patient gave birth to an illegitimate child, and from this time until she was twenty-three was insane, becoming at one time so violent that it was found necessary to transfer her to an asylum, where she remained six months, and was then discharged. When twenty-six she married, and her mental condition was apparently good until six years later, when she was again put in an asylum, this time remaining six or seven years. She has no recollection of about two years of this period, but for the remainder of the time considered that she was a military prisoner. It was during these years that she imagined herself pregnant, and so informed her nurse, cherishing the delusion fourteen months. After her discharge from the asylum she lived away from her friends, conducting herself well until a few weeks before she entered the hospital, when she went to her sister's, and informed her that she was seven months advanced in pregnancy, and was confirmed in her statement by the family physician, by whose advice she was sent to the Lying-In Hospital, November 22, 1878. The day after she entered the hospital she was examined, and found not pregnant. The evening of the second day she was in the hospital she told the nurse she should be confined before morning, and requested her to get the baby's clothes all ready. She slept quietly all night, and the next morning declared she had been delivered and the baby secreted; and so began a search through all the wards, which resulted in her claiming as her own a child two weeks old, basing her claims on the fact that the child's wrists were a little reddened, and looked as her own did when she had them in hot water. So she dressed the baby in her own baby clothes, and tended it all day, reluctantly giving it to its mother at night. The next morning she had apparently forgotten all about the child, as she busied herself knitting some socks for her expected baby; nor did she, during the remainder of

her stay, make any allusion to it. When she left the hospital for an asylum she said nothing about her own pregnancy, but seemed also to have forgotten that.

This case in so many respects resembled a well-marked case of so-called "spurious pregnancy" that it was not to be wondered at that the physician by whose advice she was sent to the hospital had been deceived, although he had made a "somewhat hasty vaginal examination."

Reports of Societies.

PROCEEDINGS OF THE BOSTON SOCIETY FOR MEDICAL IMPROVEMENT.

T. M. ROTCH, M. D., SECRETARY.

MAY 10, 1880. DR. JAMES C. WHITE, permanent chairman, presided.

HYDROPHOBIA.

DR. ABBOT read a report on a well-marked case of hydrophobia, occurring in a young man who had been severely bitten some months before by a flying squirrel, which he had captured at Forest Hill, near Boston, and which he had taken from its young. No information of any other animal bite could be obtained. The case was fatal.

DR. FITZ made a statement of the anatomical changes found at the post-mortem examination of Dr. Abbot's patient. Hemorrhages were present in the lungs, and extensive alterations in the medulla. The latter corresponded with those previously observed by the reporter, by Dr. Gowers, and by certain other writers who had recently investigated the lesions found in this disease. He showed several sections of the medulla in which were hemorrhages, both parenchymatous and within the perivascular spaces; also miliary abscesses and the accumulation of indifferent cells within the adventitia of the smaller veins and arteries.

DR. BEACH said that in this case the evidence of inoculation by a rabid animal was insufficient, but that fact would not invalidate Dr. Abbot's diagnosis of hydrophobia. The boy was fond of animals, and the possibility of an inoculation of abrasions independent of his knowledge must be admitted. Dr. Fitz has again corroborated the microscopical observations of Gowers, defining changes which resembled those described by Benedikt, Coats, Clifford Allbutt, and Hammond. More recently, Ross¹ has made a report on four cases of tetanus and six of hydrophobia. His observations are confirmatory of those already mentioned, excepting Gowers's description of the clot within the blood-vessels.

Upon comparing sections from the cases of tetanus and hydrophobia, he found similarities which warranted him in stating that the groups of cells which are shrunken and altered in hydrophobia are also affected in tetanus,—the description of one applies to the other; but the vessels in tetanus are *not* surrounded by cells, as they are in hydrophobia. Gowers holds that the distribution of the lesions, their intensity in the lower part of the medulla and the neighborhood of certain nuclei, constitutes a distinguishing character by which three out of four cases of the disease may be recognized.

¹ Transactions of the London Pathological Society, 1879, page 215.

The relation of the pathological changes to the symptoms is yet an open question; in fact, the lesions in the cord may have been simply coincident with the symptoms, or possibly due to the mode of death, though in Dr. Curtis's interesting paper¹ we have most important evidence connecting the symptoms with the respiratory centre of the medulla.

Should the pathological changes in the medulla, observed during the careful investigations of Dr. Fitz and others, be linked so firmly as to leave no doubt of their connection, the treatment of the wound will be the same as now, until it can be proved that efficient cauterization of the wound is ineffectual. The wounds made by a rabid animal demand the most active treatment on the part of the surgeon. While any uncertainty exists as to the rapidity with which the virus is absorbed, the patient is entitled to the benefit of the doubt. As yet no unquestionable case of hydrophobia has been cured; therefore the risks involved by the cauterization of extensive lacerations are justifiable. A cicatrix resulting from a wound made by a rabid animal should be excised and cauterized. The wound made by a rabid animal and that from a dissecting instrument can hardly be compared for the purposes of treatment. It is true that a bad wound from a subject dying from puerperal fever or peritonitis may give rise to little or no disturbance, even if *not* cauterized; but should the dissecting wound produce the *worst* symptoms,—for instance, a lymphangitis extending to the shoulder, with suppuration of the axillary glands and pleurisy,—under appropriate treatment the patient may recover. It follows that a dissecting wound need not be cauterized to save life. Can we say the same of a bite from a rabid animal? The most reliable statistics that can be obtained show that thirty-three per cent. of those bitten by rabid animals, including mild and severe cases, and cauterized more or less efficiently, fall victims to hydrophobia; but in cases where cauterization has *not* been practiced exactly eighty-three per cent. of those bitten die. Another argument in favor of cauterization of wounds is that it allays the fears of nervous and hysterical patients. Virchow states "that the physician should impress upon the mind of the patient a conviction of the efficacy of treatment."

The sucking of wounds to withdraw virus is unnecessary if an efficient cauterization is practiced. It exposes a second person to the danger of inoculation through the slight cracks or abrasions of the mucous membrane of the mouth, which any one may have and not be aware of the fact.

The actual cautery or the most careful application of the strongest mineral acids to the wounds should be the treatment. Excision of the wound has no advantages over cauterization, but exposes the subject to fresh chances of inoculation. The cautery discolors the surface of the wound in such a way as to leave no doubt in the mind of the one who uses it as to its application to every part of the uninoculated tissue. It is always available, and could be used by those who would hesitate to excise through fear of hemorrhage. Lunar caustic is too weak an agent where life depends on the *certain* destruction of the virus. As a palliative measure, tracheotomy to relieve asphyxia has been proposed by high authorities, but so far as I know with no relief to the symptoms. Chloroform, opium, and possibly the bromide of ethyl offer the

most relief. The latter, from its unirritating action upon the respiratory tract, may prove of service where ether and chloroform do not act well.

Dr. FITZ remarked that in the early treatment of the bite from a rabid animal he was unable to appreciate the advantages of thorough cauterization, unless it could be performed immediately after the biting had taken place. He thought the absorption of virus was likely to take place with a rapidity corresponding to the rate of flow of the blood and lymph currents. A long period of incubation did not seem to him indicative of slow absorption, as it is well known that the effects of an inoculated poison may not be manifested till long after its introduction. The reports of immunity from symptoms when cauterization had taken place some time after the bite of the animal might well be attributed to the fact that different individuals present a widely differing susceptibility to the action of the virus. When a number of persons are bitten by one or by many dogs, the percentage of those becoming hydrophobic has been repeatedly shown to be very small. Whatever remedies, therefore, might be early applied would apparently prove beneficial in a large number of cases; but he doubted if the proportion of recoveries would be any greater than that to be determined by observing what might be called the natural history of bites from mad dogs when not interfered with by any so-called abortive treatment.

Dr. FOLSOM remarked that statistics of the results of treatment of bites of rabid animals had been kept in France for some years, and that it had been shown that where the wound had been cauterized with the hot iron no deaths from hydrophobia had occurred; while where only nitrate of silver had been used hydrophobia followed in almost every case.

Dr. T. B. CURTIS thought that the favorable results attributed to the energetic treatment of dog bites by cauterization or excision were likely to be more apparent than real, and that the immunity from hydrophobia enjoyed by a large proportion of those so treated was more plausibly explained by the recognized infrequency of positive inoculation in cases of rabid-dog bites than by any prophylactic or remedial influence exerted by such treatment. With regard to the statistics which are supposed to demonstrate that, in cases of rabid-dog bites, a larger proportion of patients treated by cauterization escape the disease than of those left untreated, there is an element of fallacy, inasmuch as cases of successful expectant treatment, in which nothing is done and disease is escaped, are much less likely to be followed up and recorded than cases in which an energetic treatment of the injury has apparently served to prevent the development of the dreaded disease. Reasoning from the analogy of hydrophobia with some of the other virulent inoculable diseases which are better known, there is little evidence to encourage hopes of our being able to prevent the development of hydrophobia when once the insertion of the virus has been effected. Experiments with vaccine virus, with the virus of glanders and of charbon, show that absorption takes place almost instantaneously. With regard to the utility of exciting the scar of a healed rabid-dog bite, there would seem to be still less reason to expect any beneficial result. Syphilis is a disease which somewhat resembles hydrophobia by the long duration of its period of incubation; but it has not been found possible to modify the development of constitutional syphilis by surgical means.

¹ Boston Medical and Surgical Journal, November 7, 1878.

ures directed against the lesion through which infection has taken place.

DR. WEBBER asked whether the changes in the medulla were to be considered primary or secondary.

DR. FITZ said that they must be primary, and that they were independent of the blood-vessels.

DR. WEBBER said: There is in some cases more or less inflammation of the nerves in the neck relating to deglutition, as the recurrent and superior laryngeal and pneumogastric. As the symptoms in this case had existed for several days, it might be possible for the cord to have become affected secondarily. The changes in the blood-vessels are seen in other diseases, as in certain cases of myelitis, in general paralysis and other forms of insanity, and in cerebral hemorrhage.

One of the most marked cases which Dr. Webber had ever seen was in a case of meningeal hemorrhage in a syphilitic patient. Charcot describes such periarteritis in cerebral hemorrhage. But in all these cases the change is much more generally diffused than in the present case. The limitation of the change might lead to a suspicion that it was secondary. The so-called military abscesses are apparently of a different nature, yet may they not also be secondary and dependent upon the change in the blood-vessels?

DR. DENNY spoke as follows: Through the kindness of Professor Gudden, of the University of Munich, I had the opportunity of examining a series of four hundred and fifty micro-copic sections through the brain and medulla of two dogs, two horses, one ox, and a man, that had all died with undoubted symptoms of hydrophobia. These were partly colored by carmine and partly by fuchsin, which showed the smallest trace of increase of lymph cells or of pus. This was in 1876, when Professor Benedict's theory in respect to the pathological anatomy of hydrophobia had been but recently published, and attention was directed especially to the search for military abscesses, which he regarded as both constant and as secondary changes in hydrophobia resulting from thromboses and coagula in the veins.

The changes found were, in brief, besides the engorgement of capillaries and veins, already mentioned, collections of white blood corpuscles within the vascular membranes, and nothing more that was abnormal.

In the white substance of the brain of the ox there were star-shaped connective tissue cells, resembling increased and hypertrophied connective tissue cells of the neuroglia. These sections were made by Dr. Forel, lecturer on psychiatry, and tend to the conclusion that military abscesses are not pathognomonic of hydrophobia and are not primary.

DR. A. H. NICHOLS remarked that the notion, originating with Dr. Hammond, that hydrophobia could be developed spontaneously in a female dog in heat, or that such an animal was particularly predisposed to the disease, was based on the unsatisfactory evidence of two imperfectly observed cases, and was contradicted by the concurrent testimony of those familiar with dogs. This hypothesis, which, though seemingly harmless, might be conducive to great injury to dog owners, is disproved by the fact that there has never been recorded a single well-authenticated instance in which hydrophobia in a dog has been traced to the bite of a non-rabid bitch in heat; and were this mode of origin possible each female dog would then constitute periodically an unmistakable focus of infection, being apt when in this condition to snap at and bite the greater number of male dogs which approach her.

DR. WILLIAMS remarked that the cases of hydrophobia cited by Dr. Hammond as having been produced by a bitch in heat did not seem to him to be authentic.

DR. J. J. PUTNAM referred to the theories of the hydrophobic paroxysm advanced by Dr. Curtis and by himself two years ago, and said that he had become still more convinced than ever that these paroxysms were essentially psychoses, though centring on the condition of respiratory distress. They are analogous to the struggles of a drowning person, or of one being suddenly strangled, and, again as Dr. Gowers has pointed out, to attacks of hystero-epilepsy.

The inhibition of the inspiratory centre, according to this view, is not the central feature of the paroxysm, and need only be present sufficiently to excite, — or so that the fear of it should excite — the emotional outbreak, which then still further throws the respiratory mechanism, already permanently impaired, out of gear.

RAPID DEATH IN THE EARLY STAGE OF DIPHTHERIA.

DR. A. H. NICHOLS reported a case of diphtheria in which toxic symptoms were developed with unusual rapidity at the outset of the illness. The patient, a plump, healthy girl, three and one half years old, was first seen in the middle of the afternoon on the 30th ult. She had been playing about the house during the forenoon, and apparently in usual health; but after dinner a slight croupy breathing was noticed by the mother, which occasioned no anxiety, however, inasmuch as the child had been subject to trifling derangements of the air-passages. Upon inspecting the throat, which was displayed readily and without aid, the pharynx was found to present an extensive, thin, grayish-white exudation. The submaxillary and cervical glands were slightly enlarged; the pulse about 100. There was no difficulty in swallowing. At a later visit (ten. p. M.) the symptoms had become alarming, the child thrashing about, apparently in considerable distress, respiration being uniformly labored and loud and the voice hoarse and metallic. There were no suffocative spasms, however, nor was the forced retraction of the throat muscles so conspicuous as is often seen. Although it was evident that the child was rapidly sinking, it did not appear that the actual mechanical obstruction to respiration was sufficient to produce asphyxia. Yet, to give the patient the benefit of any doubt on this score, tracheotomy was performed (without an anæsthetic), though without appreciable benefit, death resulting shortly after midnight. No post mortem was obtained, but so far as could be ascertained from an examination of the interior of the larynx with a blunt probe there had not been much advance of the membrane into this organ. Death in this case, though rapid, differed from those more familiar sudden terminations occurring during convalescence, and commonly referred to syncope, and seemed due to the constitutional effects of blood-poisoning, aggravated, perhaps, by the disturbance of the respiratory apparatus.

DR. C. P. PUTNAM thought the manner of death did not well correspond with the sudden death which is characteristic of diphtheria. In such cases there is a sudden shock of some kind, which occurs at a time when the patient is otherwise apparently doing well. The onset of the attack is usually so well marked that some sudden occurrence has been sought for to account

for it, such as the formation of a clot in the heart. In this case the patient appeared to have sunk away gradually, as if from dyspnea.

Dr. FITZ stated that in a case of sudden death during convalescence from diphtheria he had found an extensive fatty degeneration of the heart. The child had so far recovered from the immediate effects of the disease that the nurse had taken the infant out-of-doors, and on her return the child died immediately after being removed from the carriage. He thought that Dr. Nichols's case was rather one of death during the progress of the disease than early in the course of the same, as the pharynx was seen to be coated with an extensive false membrane, which was likely to have required at least a period of days for its formation.

Dr. J. J. PUTNAM spoke of a case of epilepsy in a child, with very numerous fits, in which a moderate dose of bromide of potassium combined with chloral hydrate had proved eminently successful, after large doses of the bromide alone had failed to help. This combination will not suit all cases, but is sometimes very useful.

Dr. BRADFORD mentioned an unsuccessful excision of the hip-joint, where the patient died from shock. The operation presented no difficulty, and though the patient, a girl of ten, was in poor condition, she was not more so than is often seen before successful excision. After the operation the temperature, which had been over 100° F., fell to 96°, and just before death to 95°. The child rallied somewhat, but was unable to retain anything on her stomach, and died three days after the joint was excised.

Dr. FOLSOM reported a case of general paralysis of the insane. The man was brought before the court for polygamy, and sentenced for a number of years. He was a man of good position and education, and quite fond of his wife. At the state-prison he could not work, because he could not concentrate his attention on any special work. Last week Dr. Folsom examined him, and found that he had all the symptoms, extravagant delusion and motor perturbations, of general paralysis of the insane. Dr. Folsom had no doubt that his second and third marriages were the result of the disease in its beginning. Dr. Folsom had found four other men, who had also been imprisoned and were in the state-prison, who were probably insane at the time of imprisonment.

Dr. ROTCH reported the result of an experiment made by him on the cadaver of an infant, where an artificial pericardial effusion having been produced an aspirator needle was introduced in the fifth right intercostal space, one and a half cm. from the border of the sternum, and the fluid came out freely through the needle.

PROCEEDINGS OF THE SUFFOLK DISTRICT MEDICAL SOCIETY.

T. M. ROTCH, M. D., SECRETARY.

FEBRUARY 28, 1880. DR. CALVIN ELLIS presided.

THE RADICAL CURE OF HERNIA.

Dr. J. H. WARREN presented a report of cases of hernia operated upon for radical cure by injecting the hernial rings, which he had read before the Otsego County Medical Society, New York.

He thanked the profession for the encouragement he had received while endeavoring to perfect and pre-

sent to them his operation as improved by a new instrument and mixture for injecting the hernial rings. He spoke of Velpeau, Pancoast, and J. M. Warren having injected the hernial rings through a canula, or by first cutting down upon them and then injecting. Dr. George Heaton was the first to inject hypodermically with any satisfactory result.

Dr. Warren gave the result of an operation made July 10, 1879. A perfect occlusion of the rings followed the injection with Dr. Heaton's old instrument and mixture. The ruptures were large and inguinal; one side had existed for over two years, the other one year and a half. This patient re-ruptured himself on one side at the expiration of twelve or fifteen days, by coughing and forcing down. His third, fourth, and fifth operations were on enormous double congenital hernia; patient aged between forty-five and fifty. One side was successfully closed; upon the other, after a second injection, an abscess formed, which Dr. Warren thought was caused by the patient's resuming the upright position too soon after operation, and also that the abscess caused an absorption of lymph effused which allowed of some omental protrusion. Although one side is perfectly cured, the other is only partially occluded, but still retains the intestines fully within the rings. Operations six and seven were upon oblique inguinal hernia. July 30th, patient, aged sixty-two years, had been ruptured over forty years. At the expiration of twelve days after the operation the ring was found successfully closed, and continued so for two months. The patient then relaxing in his efforts to keep the bandage properly adjusted, the hernia partially returned. With the new and more stimulating mixture he reinjected him October 6th. The result of this operation was to more fully close the ring and control it, and successfully retain the intestines within the abdominal cavity.

In addition to these, he gave the history of two inguinal, two femoral, and one umbilical hernia. With these latter he operated with his new instrument and mixture, of which he has sent the following formulas and a short description:—

For infants and children to the age of five, for accidental or congenital hernia, use the aqueous extract of oak bark of Dr. Heaton's formula; for children five to fifteen years of age, extract of oak bark distilled to the consistency of glycerine, with ten drops to the drachm of sulphuric ether; for old and long-standing hernia, the latter extract of oak bark with one drachm of absolute alcohol to four of the extract, and one drachm of sulphuric ether with one or two grains of sulphate of morphia.

Dr. Warren's instrument consists of a barrel holding a drachm or two, and through a fenestrated opening the graduations can be read. It has a valve attachment, which will allow one to sixty drops to pass from the barrel through the spirally twisted needle which is joined to the lower end of the barrel by a metal cap. This cap allows the needle fitting accurately to revolve upon a ruby or diamond pierced with an orifice for the exit of the fluid. The piston is forced down upon the fluid by means of a spiral spring, which has sufficient force to eject the fluid upon the parts at right angles.

It will be seen that I have given the history of twelve operations on genuine ruptures of various kinds. This does not include all that I have operated upon, but only a few very interesting cases.

Of twelve cases reported, the first two were partial failures, and one later. Two of these are soon to be

reoperated upon. Dr. Warren had some doubts as to the possibility of retaining the large congenital hernia, but as the patient was very anxious for another operation he proposed to perform it. These included all of the unfavorable cases that he had met with thus far.

Upon infants he had never operated. The youngest patient was four years old. Mechanical appliances, such as a good truss or elastic bandage, he had found productive of good results. He preferred a bullet partially flattened and fastened to a linen bandage, because the compression of the abdominal muscles by the elastic bandage prevents their development, and consequently the closure of the rings, and also because these muscles are liable to be thinned by the constant pressure, and forever weakened.

COLOR-BLINDNESS.

APRIL 10, 1880. DR. B. JOY JEFFRIES gave a detailed statistical account of his more than thirty thousand examinations for color-blindness among males and females. These investigations were commenced for the scientific purpose of deciding the percentage of this chromatic defect among males and females. They have, however, led to very practical results by the control of color-blindness and visual defects in the United States army, navy, and marine hospital service, where already the method of Professor Holmgren has been adopted, and Dr. Jeffries's volume supplied as the standard to medical officers. The value and importance of physical examinations in the merchant marine was explained, and why he urged it and an international commission before the naval committee of Congress. The examinations of railroad employees by officials as hitherto carried out were shown to be useless and dangerous. The State of Connecticut has the honor of being the first to enact judicious laws for the control of color-blindness and visual defects amongst railroad employees, the tests for which are to be carried out only by medical experts as they are in Europe.

DR. WADSWORTH said that he did not think that the matter could be put so strongly in regard to railroads as it had been lately. Many more color-blind persons are now found than before, and there is no doubt that men are employed on railroads who cannot distinguish red and green lights. Men who are not physicians, but who have some knowledge of physics, some education, and some common sense can learn to test for color-blindness. As to visual defects, they are often such as to impair a man's usefulness as an engineer while he is young, but which ought to be remedied by glasses, if possible, as he gets older. It should be understood that the wearing of glasses does not necessarily show that a man does not see well, for with glasses they often can see as well as any one. Men often do not wear glasses when they ought, for fear of losing their work.

DR. HUNT criticised Dr. Jeffries's remarks and previous writings on the subject of color-blindness.

DR. C. E. WING read a paper on The Modern Abuse of Gynecology, which has been published.

DR. L. FOSTER read a paper on the False and the True in Therapeutics.

PROFESSOR BUTTERFIELD made some interesting remarks on visible speech, and explained the method of using it.

DETERMINATION OF UREA.

APRIL 24, 1880. DR. F. H. WILLIAMS read a paper entitled A Simple Method for determining the

amount of Urea in the Urine, and exhibited an apparatus adapted for this purpose.

PUERPERAL TETANUS.

DR. C. M. GREEN read a paper on Puerperal Tetanus, of which the following is an abstract:—

On the 7th of January, 1880, a nervous married woman, thirty-six years of age, three months advanced in her seventh pregnancy, suffered her third abortion. Her medical attendant subsequently informed me that the placenta was extracted manually and the copious hæmorrhage checked with a tampon. The woman was much reduced in strength, but at the end of a week was about her usual work.

Thirteen days after the abortion I was called to see the woman, and found her suffering severe pain in the head and both sides of the neck. Two days later there was great pain in the small of the back; partial trismus ensued, and there was a sense of constriction in the throat, but liquid nourishment was taken without difficulty. The woman lay propped up in bed, with the head thrown backward; when she was raised rigidity of the back was noticed. There was no abdominal pain or tenderness, and there was no vaginal discharge. For two days the same condition obtained, the temperature being normal and the pulse 130, regular, but weak. The next day there was rigidity of the legs, and the woman began to have tonic convulsions; the head was thrown violently backward, the arms and legs were rigidly extended. These convulsions continued at variable intervals for three days, the temperature meanwhile rising to 101.9° F.; but toward the close of the third day the convulsions recurred about every half hour and became more violent, until death ensued, apparently from apnoea. The intellect was clear throughout.

The attendance on the patient was such that several important matters were not made known to me before her death; I witnessed none of the convulsions. The case as I observed it seemed one of hysteria, with which the patient had suffered before. But after death had occurred, and it was evident that an error had been made in diagnosis, careful inquiry among the patient's friends elicited evidence which left no doubt that the case was one of tetanus. A post-mortem examination was not allowed.

Puerperal tetanus has a very scanty literature, and the cause of its origin is still undetermined. Sir James Simpson¹ believed that tetanus was more likely to supervene when the uterine surface was in such a state of lesion as to lead to protracted hæmorrhage, or when the maternal canals had been irritated by the tampon; and he admitted that possibly some special blood poison in the placental area or elsewhere might give rise to tetanus.

Schroeder² believes it to be probable in the highest degree that tetanus arises from infection, or "at least by some peculiar irritation of a puerperal wound;" and that it most frequently ensues after considerable hæmorrhages, especially when the tampon has been used.

Dr. Angus McDonald³ has reported a case of tetanus occurring on the eleventh day after a natural labor. The autopsy revealed in each corpus striatum a vast number of small extravasations, and in the vena cava and straight sinus a large, dense, firm, and adherent

¹ Selected Obstetrical Works, page 569.

² Lehrbuch der Geburtshülfe, 7te Auflage, s. 770.

³ British Obstetrical Journal, November, 1875, page 516.

thrombus. Referring to the opinion of many physiologists that the corpora striata and quadrigemina are the great motor centres of the whole body, irritations of which will produce tetanic convulsions, McDonald points out that as soon as the straight sinus became impermeable these motor centres, whose veins ultimately discharge into this sinus, must have been thrown into such a state of congestion as to cause the irritation necessary to produce muscular spasms. He therefore believes it most plausible that congestion of and extravasations into the cranial motor centres, resulting from venous thrombosis, are the proximate and the peculiar (perhaps septic) condition of the blood which exists in the puerperal period, the predisposing cause of puerperal tetanus. On the other hand, Surgeon Major Ratton¹ says that "the group of symptoms known as tetanus is produced by peripheral nerve irritation," and that so-called idiopathic tetanus is due to intestinal irritation from worms, or to puerperal or menstrual troubles in which peripheral nerves are irritated. Lattey² reports the case of a woman suffering with obstructive dysmenorrhœa, who was seized with convulsions characterized by complete opisthotonos and visus sardonius. The convulsions occurred at three successive menstrual periods, and drugs had no effect in relieving them; but after incision of the cervix, which relieved the dysmenorrhœa, the spasms ceased.

My own case of tetanus, devoid as it is of post-mortem evidence, unfortunately gives no clew to its origin, but it seems most probable that some vessel in or near the motor centres became occluded by a thrombus, which gradually led to such congestions and extravasations as to irritate these centres, but which did not result in sufficient effusions or hæmorrhages to impair consciousness. Or possibly the spinal motor ganglia were in such a condition of irritability that some slight irritation of peripheral nerves in the placental area was sufficient to induce the convulsions.

Pending further investigation of the causes of tetanus, it seems to me that the present understanding of the subject may be stated as follows:—

(a.) That the peculiar condition of the blood of a puerperal woman is a predisposing cause of tetanus.

(b.) That profuse hæmorrhage in abortion or labor at full term intensifies this cause.

(c.) That this cause becomes effective either through irritation of the motor centres or spinal motor ganglia, by phlebotic thrombi and consequent congestions and extravasations, or by leading to structural changes through mal-nutrition.

(d.) That if the blood is specially septic it may become an efficient cause of tetanus by directly irritating either the motor centres or the spinal motor ganglia.

(e.) That if through structural changes the spinal motor ganglia are in a state of abnormal irritability, peripheral irritation of the uterine or vaginal nerves may be a sufficient proximate cause of tetanus.

DR. CHEEVER remarked that he had lately had two cases of tetanus at the City Hospital, and that both had ended fatally. The first was a man who had his finger crushed, and was exposed to cold, who entered the hospital in a state of violent tetanic convulsions, and died in three days.

The second case upheld the theory brought forward by Dr. Green in his paper, namely, that tetanus was caused by peripheral irritation, and not by a central lesion of the brain or cord.

A man had been operated on for hæmorrhoids by ligatures, and remained in the hospital for two weeks. The rectum at that time had not quite healed, though the motions from the bowels were easy. He chose to leave the hospital, and in three days he returned with marked tetanus. There was no disturbance with the bladder or rectum. The tetanic condition lasted for sixteen days, when he finally died in a convulsion.

The gross appearances of the brain and cord presented nothing abnormal, and gave no evidence of softening or thrombus. Pus was found between the rectum and bladder, and in fact a diffused pelvic cellulitis, emanating apparently from an unhealed ulcer in the rectum.

DR. WEEKS had met with a case of tetanus in a man whose finger was crushed while at sea, and who finished the amputation with a hatchet, and was then exposed to cold and wet for ten days. Dr. Weeks was then called in, and gave chloral in large doses without manifest influence on the brain. He also treated the case freely with stimulants.

DR. A. N. BLODGETT remarked that he had met with cases of somnambulism following the use of chloral.

PATHOLOGICAL SPECIMENS.

DR. W. F. WHITNEY presented specimens of Carbolic Acid Poisoning, Pseudo-Hypertrophic Muscular Paralysis, and Cyclops, and made the following remarks:—

CARBOLIC ACID POISONING.

The first specimen consists of the stomach and œsophagus from a case of poisoning by carbolic acid. The specimen was presented to the Warren Anatomical Museum by Dr. F. A. HARRIS, who gave the following history of the case:—

This stomach is from the body of a sailor, who had taken a large drink from a jug which he supposed contained whisky. He told the steward of the steamer that he had taken something from that jug, and the steward, knowing that it was poison, ran for some oil, but before he returned (after an absence not exceeding three minutes) the sailor was entirely unconscious, and remained so till he died. There was no spasm and no noticeable symptom aside from the feeble and fluttering pulse and a slight frothing at the mouth.

Attention is called to this case chiefly that proper caution may be observed in the use of carbolic acid. It is so generally and so freely employed as an antiseptic, and is so often left about in saucers and bottles without proper labels, that similar accidents are constantly liable to occur. The resemblance in odor to Scotch whisky makes it easily liable to be mistaken for that article. The results observed in the recorded cases show that its action is remarkably rapid, and almost always fatal. The dose required to produce a fatal effect is quite small, ten drops being probably sufficient to kill an adult, though the amount usually taken in cases observed has been much in excess of that amount. The average duration of a case is from half an hour to four hours, the shortest case being ten minutes, and the longest sixty hours.

The specimen presents the appearances characteristic of the ingestion of the acid. The lining of the œsophagus is contracted, and shows well-marked longitudinal folds. The surface is smooth, and has a peculiar bright, slightly yellowish-white color, closely approaching that of fresh-pulled molasses candy.

¹ The Brain, January, 1880. Paper on the Cause of Tetanus.

² The Lancet, January 17, 1880.

The stomach was also strongly contracted, and the summits of the rugæ were marked by white lines, while in the interstices was found a dirty reddish granular detritus. The difference in the appearance of the stomach and œsophagus is easily explained by the longer time the former organ was subjected to the caustic action of the acid.

PSEUDO-HYPERTROPHIC MUSCULAR PARALYSIS.

The second specimen is a leg and foot from a boy affected with pseudo-hypertrophic muscular paralysis. The specimen came from a dissecting-room subject, and no history could be obtained. The subject was a colored boy, apparently from twelve to fourteen years of age. The muscles of the calf of the leg had preserved their outline, and were a little larger than normal, but their color was changed throughout to a yellowish-white, and their cut surface had all the appearances of fat. Microscopic examination showed the tissue to be composed of fat cells, among which were seen narrow bands of connective tissue. Muscular fibres were not to be recognized, even in muscle from the back, where the changes were not so far advanced. This failure to find the fibres may be due to the post-mortem changes which they had undergone.

CYCLOPS.

The third specimen is a cyclops, with anterior hydrecephalocoele. The case occurred in the practice of Dr. ISAAC F. GALLOUPE, of LYNN, who presented the specimen to the museum, and gave the following history: The mother of the fetus was an American, aged thirty years. "She had had one well-formed child at full term that lived but one week; she afterwards miscarried at seven months with twins, also well formed. No other case of deformity has been known in the family, except one of hare-lip. The labor was not of long duration, and was aided by passing the finger into the rectum until the chin was reached (the occiput being towards the pubes), and pressing out the head in an interval between the pains. The mother expected to be confined about six weeks later."

The fetus measured thirty-eight cm. in length, and weighed about 1125 grammes. The trunk and limbs were well formed. From the anterior portion of the head projected a fluctuating tumor, twenty-three cm. in diameter, involving the forehead and all of the face from 0.5 cm. above the mouth. The tumor was covered with skin continuous with that covering the rest of the head, except at a point in the lower anterior third, where was a slightly lozenge-shaped space, covered by a transparent membrane, and surrounded on its upper and lower borders by a slightly thickened portion having faintly marked radial striations on it (edges of the eyelid).

Upon dissection, the interior of the tumor was found to be directly continuous with the cavity of the skull; contained a watery fluid, and on its inferior surface a layer of brain substance. Corresponding with the transparent portion above mentioned was found a small flattened sac lined with a coat of black pigment.

The opening into the skull was bounded on the upper portion and sides by the frontal bone, the edges of which were markedly everted. The lower edge of the opening was formed by the malar bones and the lowest part by the orbital portion of the superior maxillary, between the anterior portions of which were two small triangular bones, probably representing the lac-

rymal bones. The roof of the mouth was very narrow, and there was a well-marked central ridge running the entire length. Situated between the pterygoid processes and filling the space between them was a triangular piece of bone, formed apparently from two lateral pieces, and joined to the central ridge of the roof of the mouth by a short and flattened spine. This plate, which is characteristic of the cyclopean skull, was formed by a coalescence of the palatine bones with the vomer. The nasal cavity was entirely obliterated, but the germs of the ethmoid and turbinated bones were to be seen in a little cancellated bone structure in the roof of the mouth.

Dr. WEBBER remarked that he had seen five cases of pseudo-hypertrophic muscular paralysis and that in four of these cases the enlargement of the calves was quite evident; in the fifth there was no enlargement. There were two adults, and one case was sixteen years old. Two out of the five cases were girls. Three of the cases not only had enlarged calves but also atrophied upper extremities; this latter symptom almost always comes on late. There are some facts in regard to this disease which point to its being of nervous origin, though this is not proved. — Dr. CUSHING remarked that a rather curious parallel might be drawn between this disease and color-blindness in respect to its occurring mostly in boys and being hereditary on the mother's side. — Dr. WEBBER said that the two girls referred to in his cases were sisters.

IODIDE OF ETHYL FOR DYSPNEA.

Dr. R. M. LAWRENCE read a paper on ethyl iodide, which appeared in the JOURNAL for April 29, 1880.

Recent Literature.

A New Study of Cerebral Cortical Localization. The Effect of Willed Muscular Movements on the Temperature of the Head. By R. W. AMIDON, A. M., M. D.

The Archives of Medicine for April, 1880, contains a valuable contribution to cerebral physiology in the form of the above paper, an elaborate prize essay, evidently the result of prolonged and careful study.

Following out the hint given by the statements of several observers, that localized inflammatory diseases of the brain are revealed by local elevation of the temperature of the scalp, and that similar though usually slighter effects follow mental effort, Dr. Amidon has investigated the question whether the same might not be true of muscular effort, inasmuch as it is now well established that the cortex of the brain in the parietal region contains "centres" which correspond to definite groups of muscles on the opposite side of the body.

The method of research was to distribute a number of thermometers over the side of the head, then to let a muscle—the biceps, for example—be strongly energized for five or ten minutes, and five minutes later to record the temperatures. If the mercury in one of the thermometers was found to have risen, the rest were concentrated round that one, and the experiment repeated, till the localization had been made as exact as possible.

In this way he claims to have been able to map out the various "centres" with an exactness approaching that obtained through the electrical excitation of the

cortex by Hitzig, Ferris, and others, and to have found distribution analogous to theirs.

The thermometers used were flat-bulb mercury instruments, and the rise varied from a few tenths of a degree F. to more than two degrees.

We shall look with interest for the results of the repetition of his experiments by others. J. J. P.

Lectures on the Diseases of Women. By CHARLES WEST, M. D., F. R. C. P., etc. Fourth edition, revised, and in part rewritten, by the Author, with numerous additions by J. MATTHEWS DUNCAN, M. D., LL. D., etc. London: J. and A. Churchill. 1879. Pp. 676.

It is with considerable interest that we have turned to this fourth edition of Dr. West's book, which for a long time deservedly held so high a place in gynecological literature, — an interest which has been increased by the association of Dr. Duncan's name with that of the author in this revised edition. The book must keep its place in our library, even though so many new and popular volumes in this department have lately appeared, not because it is up to our present standard of gynecological knowledge, — for so we do not recognize it, — but because it presents the conservative views of the author in a style so clear and beautiful that its importance must always be felt by those who desire to deal fairly and cautiously with their patients, and its influence must go far to prevent the department of which it treats from falling into the hands of specialists, bigoted in their ideas, who do but disgrace the profession.

The publishers, unfortunately, send out the book in a somewhat unfinished state. The active practitioner of to-day is loth to take time to cut the leaves of a volume of nearly seven hundred pages.

It is very pleasant to see expressed throughout the book the author's great consideration for, and his feeling of delicacy and tenderness toward, the patient; and we are sure that the physician would, in many cases, find his ability to benefit his patient much increased by a strict adherence to the advice so acceptably given here.

Dr. West does not consider the operative part of gynecology, and where, in a limited number of instances, reference is made to such treatment it is usually in derogatory terms. No work on the diseases of women can be considered complete in these days which so scrupulously avoids all description of the necessary operations. The almost heroic extent to which the author advises the use of leeches, blisters, and medicines, and the strict avoidance of even the minor operations upon the uterus, show his firm belief in medicinal measures in gynecology; but, judging from the length of time before relief is given the patient in some instances, and the guarded prognosis expressed in many other cases which should apparently yield to operative measures, with perhaps less danger and certainly less suffering to the patient, we must believe the course recommended much more unsatisfactory and ineffectual than that usually followed by the gynecologists of to-day, at any rate by those of this country. We can hardly believe that one of them would express himself as does the author on page 213, where, referring to the treatment of uterine misplacements, he says, "The principle upon which I usually act in the management of these cases amounts pretty much

to this: that, to the best of my power, I take care of the general symptoms, and leave the misplacement to take care of itself."

From the association of Dr. Duncan's name with that of the author in this edition, we had expected to find the diagnosis, pathology, and treatment of the diseases of women brought up, in some measure, to the level of the latest thought and knowledge of these subjects; but in this we are greatly disappointed. After searching diligently for the additions made by Dr. Duncan, which, when found at all, are carefully inclosed in brackets, we conclude that he has given little to the book except his name, which appears in large letters on the back together with that of the author. We can but feel that under the new partnership we have lost something of our old friend, and gained but very little from our new one. And this is not from lack of opportunity for improvement, especially in respect to diagnosis, pathology, and treatment; for these are sadly behind the times. Highly as we respect the author, to whom we have long looked up as one of the leading gynecologists of the older school, we must remember that the department of the diseases of women has taken rapid strides in the past few years, notably in the very directions in which, as we have already stated, the book seems most lacking. Dr. Duncan has lost the golden opportunity of making it a thorough treatise upon modern gynecology, invaluable to us as an exposition of what is at present known in this department, as it was so long in the past in reference to the knowledge and procedures of the old school. Now, it must remain as our old and respected friend, whose strength lies in its great conservatism.

The Essentials of Anatomy. By WILLIAM DARLING, M. D., F. R. C. S., and AMBROSE L. RANNEY, M. P. New York: G. P. Putnam's Sons. 1880.

It is not easy to do justice to a book without considering the circumstances under which it has been written and the purpose it is meant to fulfill. The authors state in the preface that "this work is not intended to supplant, but rather to accompany, more exhaustive treatises." They have tried to make it contain the essentials of human anatomy, and have made much use of tables and what we may call tabular diagrams in presenting it to the student. The authors must not be surprised if these methods do not appear as satisfactory to critics as to themselves. A diagram drawn before the class, and explained as it grows by the skillful lecturer, who knows precisely what it is to show, and who emphasizes the important points, is a very different thing from its counterfeit presentment in a book. This work gives us a high opinion of the lectures delivered by the gentlemen who wrote it; yet as a work on anatomy, taken by itself, it strikes us, we must confess, as unsatisfactory. There is a want of description and an excess of mechanical assistance to the memory. A student who trusted to this book alone might pass a wonderful examination and be utterly ignorant of anatomy. There are many things in it which we like very much; as an instance, the table on page 85, comparing the corresponding parts of the vertebrae in the three regions; but the book will not do as the chief text-book of the student. It is more to be recommended to one who has learned and forgotten anatomy than to one who has yet to acquire it.

T. D.

Medical and Surgical Journal.

THURSDAY, MAY 20, 1880.

A Journal of Medicine, Surgery, and Allied Sciences, published weekly by Houghton, Mifflin and Company, Boston. Price, 15 cents a number: \$5.00 a year, including postage.

All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.

Remittances by mail should be sent by money-order, draft, or registered letter to
HOUGHTON, MIFFLIN AND COMPANY, BOSTON, MASS.

THE STATE BOARD OF HEALTH, LUNACY, AND CHARITY TUB AND THE WHALES.

THE daily papers have of late devoted so much of their space to the State Board of Health, Lunacy, and Charity, and to the two members whose terms of service expire next month, that it seems desirable for us to recall to the minds of our readers a few of the facts in the case. It will be remembered that the board was created by ex-Governor Talbot, against the judgment of the two boards abolished, namely, the State Board of Health and the Board of State Charities, under the persistent efforts of Mr. F. B. Sanborn, who was then abusing various features of the dominant party administration in the *Springfield Republican*, of which he was the Boston correspondent, and of Mr. H. B. Wheelwright, whose character, we hope, is not faithfully reflected in his reputation. Mr. Wheelwright's career offers to the observing and reflecting journalist many fruitful topics of discussion, which we will reserve for future use. The "Machine" has gained something by Mr. Sanborn's giving up his position on the *Springfield Republican*, when he became a state official. The law provided that the chief subordinates of the board should be chosen with the consent of the governor (not the governor and council, as is customary), so that Mr. Talbot appointed his board, and virtually dictated to it who the executive officers should be.

The chairman of the board is Mr. Moses Kimball, who recently gave a statue to the city of Boston. The other members are Messrs. Davis, Hoadley, and Webster, of the State Board of Health, Messrs. Allen and Donnelly, of the Board of State Charities, and Drs. Hitchcock, of Amherst, Parmenter, of East Cambridge, and Wood, of Worcester; not a strong board, certainly, although there are strong men in it. The retiring members this year are Dr. Albert Wood, of Worcester, an able and efficient man, and Dr. Nathan Allen, of Lowell, who has been appointed and reappointed to office for many years, the State honoring him greatly. It is urged, and we think with propriety, that a woman (better two women) should be appointed on the board; for none of the present members, with the multiplicity of their duties, have had time to know personally much about the public institutions under their charge, while Mrs. Lowell, Miss Schuyler, Miss Cary, Mrs. Atkinson, Mrs. Ware, Miss Putnam, Mrs. Johnson, Mrs. Hammond, Mrs. Leonard, and Mrs. Richardson in this country, and a dozen ladies in England and Germany, have shown what valuable work may be done by women in the admin-

istration of public charities. The two retiring members of the board belong to its lunacy committee, which has been so much complained of by the "lunacy reformers," headed by a young woman who has been four times committed to three different insane asylums, having been discharged from one of them because she could not be longer tolerated even in a lunatic hospital. We, too, are dissatisfied with the lunacy department (Messrs. Allen, Hitchcock, Wood, and Mr. F. B. Sanborn, executive officer), but for a different reason from that given by the "reformers," and because, whatever their other qualifications may be, there is no one of that department who has any real knowledge of insanity or its treatment. In our opinion, to place such a commission as in any sense supervisors of our asylum superintendents and trustees is so extremely grotesque that, in that view of the case, we almost lose sight of its manifest injustice and the great injury caused thereby to the best interests of the asylums and the insane.

No new cases of Butler-phobia have been reported, and the epidemic seems to be over. But, soberly, is it not rather solemn trifling with a serious subject to divert from its great and legitimate field of usefulness into the ruts of the Machine a board dealing with such vast interests, and having only some sixty thousand dollars a year to expend?

Governor Long occupies a position which has been graced by Hancock, Adams, Everett, and Andrew, in a commonwealth which is honored wherever its name is known. He has an opportunity to gain the confidence and respect of those people who believe in an upright and efficient civil service.

THE PHYSIOLOGICAL LABORATORY AT HARVARD.

It is a matter for congratulation that the zeal of would-be reformers has thus far in no way interfered with the work of physiological experimenters in this country, and that the progress of science has not been so seriously obstructed as is the case to-day in England. What this department of scientific investigation has done for medicine has been ably shown in recent articles in the *British Medical Journal*. Not only have the most important problems of physiology been solved by this means, but questions of the greatest value to practical surgery have been settled. Our knowledge of the action of drugs has also increased immensely, and the value of certain articles as food for the sick has been determined by experiments on animals.

Work of this character has hitherto been carried on in the United States by individuals only, and to a very limited degree. One of the earliest attempts to organize a laboratory on a scale befitting the present needs of science, and to use it for purposes of systematic instruction as well as for original experiment, was made by Professor Henry P. Bowditch. It has now been in operation eight years or more, and may be said to serve as a model for the purpose for which it was designed. We have before us a

little book containing a collection of a number of papers describing some of the investigations which have been made by different observers in the laboratory during this time. The character of Dr. Bowditch's own work shows that he has devoted himself to the organization of his department and to the perfection of his apparatus, a number of original forms having been devised by himself. He has, however, found time to publish several valuable articles on other subjects. The most noticeable recent work which has emanated from the laboratory embraces the investigations both of Dr. Garland and of Dr. Rotch on effusions in the chest, as being instances of the value of scientific research in settling questions of a practical character. Mr. C. S. Minot and Dr. J. J. Putnam are also among the contributors to the volume. As one of the pioneers in this department, Dr. Bowditch should have the sympathy and encouragement of those who believe that it is through these channels that we may hope to shed further light on medical science. Hitherto American physicians have devoted themselves chiefly to the practical side of the healing art. That our native ingenuity and skill will enable us to shine also in scientific work, and that this department is receiving daily more respectful recognition, is becoming apparent in the increased numbers of students who frequent our laboratories and interest themselves in original investigations. To those of our readers to whom the term vivisection is synonymous with cruelty we would add that the horrors of the laboratory have passed away with the crude experimentation of earlier times, under the benign influences of anaesthesia and the enforcement of a discipline more in accord with the serious character and high aim of the objects to be attained.

MEDICAL NOTES.

— At the recent quarterly meeting of the National Board of Health, in Washington, the officers of the preceding year were re-elected. The conference with state and municipal boards of health on the subject of vital statistics was well attended, and the National Board of Health deserves the thanks of the country for bringing the matter to the attention of those men who now have it in their power to inaugurate a uniform system of registration. The various weekly mortality reports were compared, discussed, criticised, and finally left in the Washington office for the preparation of one model blank to be used in all places; nearly all of the gentlemen present finally admitting the real defects in their own methods and cordially agreeing to co-operate in rectifying them. A committee of five was appointed to confer with European statisticians, and to prepare a nomenclature of diseases for general use. The regulations with regard to quarantine were somewhat modified, as suggested by the experience of last year.

— Touching the recent petition of Boston homœopaths, the *New York Medical Record* says: "If, however, a pure homœopathic practice could be introduced into the Boston City Hospital, and its results

placed in comparison with those obtained by regular physicians, nothing more disastrous could happen to the so-called new school.

"Such experiment is not new, however, and it is hardly worth while to try it again. At Vienna and at Ann Arbor homœopathic education has been attempted side by side with instruction in scientific medicine, and it has failed. Homœopathic treatment has been tried in the wards of hospitals at St. Petersburg, Vienna, Paris, and other cities, and it has been given up as ineffective. In the present instance the homœopaths express themselves as being quite willing to have a separate building, and if anything is done in the matter it will probably be the securing another hospital. To this there can be no especial objection, if the taxpayers desire it. The New York City Homœopathic Hospital has turned out to be a harmless institution. Treating, as it does, chiefly chronic and incurable cases, it probably furnishes interesting opportunities to study the natural course of disease. Similar opportunities need not be denied Boston if she wishes them.

"Those laymen, however, who interest themselves in clamoring for the rights and proportionate representation of special medical schools ought to remember, in the first place, that homœopathy in its pristine simplicity is no longer practiced by intelligent men. There ought to be care taken, therefore, in appointing men to responsible positions simply because they claim to practice by an exclusive dogma, and on such account feel themselves entitled to a representation."

— The annual meeting of the Association of American Medical Editors will be held on Monday evening, May 31st, in the parlors of the Fifth Avenue Hotel, New York. The annual address will be delivered by the president, S. T. Powell, M. D., of Atlanta, Ga. The question of the advisability of the general adoption of the metric system by the American medical press will be brought forward for discussion.

— The fifth annual session of the Association of Medical Officers of American Institutions for Idiotic and Feeble-Minded Persons will be held at the Institution for Feeble-Minded Youth (Dr. George Brown's), Barre, Mass., commencing Tuesday, June 8, 1880, at three o'clock, p. m. The following papers will be presented and discussed: On Epilepsy, Dr. George Brown, Barre, Mass. On the Psycho-Physiological Education of an Idiotic Eye, Dr. E. Seguin, New York. Some False Impressions that prevail as to the Nature of Idiocy, Dr. H. B. Wilbur, Syracuse, N. Y.

— Bordinet treats paraphimosis as follows: He takes a hair-pin, presses the points together somewhat, and inserts the curved end under the strangulation back of the gland. He next applies a second and a third at intervals around the gland; then, drawing the prepuce forwards, reduces it with great facility, the skin gliding over the three bridges without obstruction.

— Nitro-glycerine attracts increasing interest as a remedy in neuralgic affections, but especially in the treatment of angina pectoris, in which, apparently, it is most useful.

—According to the *Medical Times and Gazette*, Dr. Curschmann, of Hamburg, has discovered that a substance called *methyl-green*, which has been lately introduced into practical histology as a staining medium, has a peculiar affinity for amyloid substance, and colors it an intense violet (*Virchow's Archiv*, vol. lxxix., Part 3, page 556). The surrounding tissues, that have not undergone degeneration, are stained green or bluish-green, and the contrast is therefore very striking, whilst the smallest spot of amyloid disease can be readily discovered. Hardly less important than this discovery is the observation that methyl-green colors so-called hyaline cysts (*in situ*) ultramarine blue, so that these also can be readily distinguished in sections of the kidney from the green-colored tissues around, as well as from the violet amyloid spots in which they may lie. Methyl-green, which can be purchased of any chemist, is used for staining in the form of a one per cent. aqueous solution. A few minutes' immersion of a microscopical section in this solution is sufficient; but sharper and more uniform coloration is produced by using a more dilute medium for a longer time. Preparations so made may be mounted in dilute glycerine, but not in Canada balsam, inasmuch as alcohol, turpentine, and oil of cloves quickly discharge the color.

—The *Louisville Medical News*, under the heading "In Mediis Tutissimus," says: "The *Ohio Medical Recorder* announces that hereafter it will not allow contributors to part their names on the side. J. Higginbotham Smythe is to have the Higginbotham knocked out of him, or come to the front with 'Jones.' We commend the taste and courage of our charming contemporary, but warn it in time that its pages will hereafter lack gynæcological communications."

—Drs. Rock and Waschmuth, of Altona, report a curious fact discovered at the hospital of that town. A typhoid-fever patient was perussed over the splenic region, and no dullness was elicited. The patient subsequently died, and at the autopsy no trace of a spleen could be found. The splenic artery was likewise absent. The other abdominal organs were normal.

—We regret to notice that so dignified a publication as the *London Medical Record* has adopted that irritating form of advertising, — colored interleaves.

—Dr. William Sharpey, the well-known anatomist and physiologist and one of the authors of Sharpey and Quain's work on Anatomy, is dead.

—Professor Schiff, the experimental physiologist, and formerly located in Florence, is now an active professor in the Medical College of Geneva, Switzerland.

NEW YORK.

—The second annual meeting of the American Laryngological Association will be held at Delmonico's, parlor No. 10, on May 31st, June 1st and 2d. The profession is cordially invited to attend the meetings. The following titles of papers have been received up to date: Dr. Bosworth, on Nasal Stenosis. Dr. Cohen, on Primary Tuberculosis of the Larynx, with specimen and microscopic sections. Dr. Cutter, on Throat Syphilis and Tubercle according to Salis-

bury, with lantern illustrations. Dr. Lefferts, on Some Practical Suggestions in Connection with the Use of the Laryngoscope in Children. Dr. Porter, on Erysipelas of the Larynx. Dr. Robinson, on Suggestions as to the Therapeutical Value of Rest in the Treatment of Laryngeal Diseases. Dr. Roe, on Fracture of the Larynx, with specimen. Dr. Rumbold, on Removal of Polypoid Growths from the Superior Portion of the Respiratory Tract, with Cases. Dr. Seiler, on A Case of Intra-Laryngeal Growth. Exhibition of modified Stoerks guillotine and tube forceps. Dr. Shurley, on The Treatment of Pharyngitis Sicca.

The nominees for active fellowship made by the council will present the following papers: Dr. W. Gleitsmann, of Asheville, N. C., on A Rare Case of Tracheal Stenosis. Dr. S. W. Langmaid, of Boston, on The Treatment of Certain Forms of Vocal Disability by the Application of the Principles of Voice Culture. Dr. E. W. Cushing, of Boston, on Membranous Laryngitis complicating a Case of Typhoid Fever. Dr. Harrison Allen, of Philadelphia, on A New Method of treating Chronic Nasal Catarrh. Dr. C. E. Bean, of Louisville, on Tuberculous Laryngitis in its Relation to Phthisis Pulmonalis. Dr. C. E. Sajous, of Philadelphia, on The Differential Diagnosis between Tuberculous and Syphilitic Laryngitis. Dr. William H. Daly, Pittsburgh, Pa., on Nasal Polyps. Dr. Wm. C. Jarvis, New York, on Hypertrophy of the Nasal Mucous Membrane. Nominations for honorary fellowship, as follows: Dr. J. W. Richards, of New York, Manuel Garcia, of London. Nomination for corresponding fellowship, as follows: Dr. Carlo Labus, of Milan.

—It is certainly a melancholy spectacle to see a man of the scientific attainments of Mr. Edison, whose inventive genius has already accomplished such brilliant results, and of which so much more has been expected in the future, turning his attention to the concoction of quack medicines; but the numerous advertisements of "Edison's Polyform," which have recently made their appearance in the newspapers, unfortunately leave no room for doubt in regard to the matter. In these remarkable notices we are informed that "suffering from the excruciating pain of neuralgia, incident upon intense application of mind upon his other wonderful inventions, and receiving no benefit from the many prescriptions brought to his attention, he, with that practical method of doing things which is bound up with him, made experiments upon himself until he perfected a combination of essential medicinal extracts, which, to his intense gratification, immediately relieved him from all his pain. Thinking, however, that what cured him might possibly not be adapted to all, by further experiments upon others he was at length convinced that his new discovery was a veritable pain-destroyer in all cases of neuralgia, nervous pains, headache, etc. . . . After much solicitation from eminent men and those of his friends to whom his discovery has been of wonderful service," the touching narrative continues, "he was persuaded to allow the preparation to be put up and sold for the benefit of the thousands of those who suffer months and years of pain without obtaining the relief sought.

Professor Edison's name will shine with even brighter lustre (if such a thing were possible) for giving to the innumerable army of sufferers a medicine which can be relied upon with certainty to cure their nervous pains." The professor's extreme modesty is shown by the fact that "in no sense does he claim that *polyform* is a 'cure-all;'" but at the same time it is only just to him to mention that "for the racking pains of neuralgia, no matter where situated, it is the evidence of all who have tried the remedy that Edison's polyform is the most wonderful reliever of pain ever compounded." This inestimable boon to the "innumerable army of sufferers," we are considerably informed in conclusion, is prepared by the Menlo Park Manufacturing Company, of New York, but is for sale by all the principal druggists and apothecaries.

— On the first of May Dr. Barker took possession of the very elegant residence on Thirty-Eighth Street, built not long since by the late Dr. Bumstead, which he has leased for five years. His partner, Dr. A. A. Smith, who has now been made full professor of Therapeutics and *Materia Medica* (instead of lecturer) at the Bellevue School, will occupy his former house on Madison Avenue.

PHILADELPHIA.

— At the last meeting of the Pathological Society Professor Da Costa read a paper upon the authenticity of tubercle, and defined its relationship to caseous pneumonia. The term phthisis he definitely restricts to pulmonary tuberculosis. An abstract of this paper will appear shortly in the department of the JOURNAL devoted to the progress of practical medicine.

— The April meetings of the County Medical Society were enlivened by the consideration of a report from the standing committee on hygiene and the relations of the profession to the public, upon cases of disease resulting from defective drainage and sewerage in the city of Philadelphia, and the propriety of legislation to prevent their recurrence. Dr. Henry H. Smith, by request, also presented a short paper on the operation of the Mutual Aid Association of the County Medical Society. Dr. Henry Leffmann read an interesting paper on the Alcoholic Liquors of Philadelphia, and exhibited the methods in use of compounding liquors. Materials for a very instructive and impressive temperance lecture could be obtained from this paper and the discussion which it elicited.

— On May 5th the regular meeting of the College of Physicians was held, at which Dr. William S. Forbes read a paper upon the action of the diaphragm in favorably influencing respiration and circulation. At the same meeting Dr. Robert S. Harris read a further communication upon the subject of Foot-Binding in China; which does not commence in infancy, as is commonly believed, but generally begins when the girl reaches about the age of five years. It has no religious significance, but is merely a custom.

— Quite a number of our prominent physicians were in attendance upon the session of the National Pharmacopœial Convention in Washington. Professor Bartholow represented Jefferson College; Drs. Henry H.

Smith, J. Howard Taylor, and R. J. Dunglison were delegates from the County Medical Society.

CHICAGO.

— The practitioners' course of lectures at the Chicago Medical College has just closed, with a class of forty. They all express themselves as well satisfied with the course.

— Considerable indignation has been aroused among certain sufferers by the present slight epidemic of small-pox in Chicago, because all patients are forced to go to the pest-house. Undoubtedly some cases are made worse by being transported in an ambulance several miles, however careful the health officers are in doing it, and possibly some deaths may be directly chargeable to this exposure. But the indignation is wrongly visited upon the health department, for it is by virtue of a city law, mandatory in its character, and not the judgment of the officials, that these removals are made.

It is a serious question whether it would not be better for the community to allow more patients with variola to remain at their homes. By such a course people would be moved more generally to get vaccinated and revaccinated at proper intervals. Taking all the cases as they occur out of the community seems to have the effect to lull the people into a sense of security that proves often exceedingly disappointing.

— Only a few weeks ago a case of death from chloroform occurred at the Eclectic Medical College. In this case the patient was a young man who had necrosis of some of the long bones, and who was debilitated to a considerable extent. Here death took place after a very small portion of chloroform had been inhaled, and there was no evidence whatever of its having been given carelessly. The autopsy did not reveal any disease of the heart, but it was thought that the brain was softer than normal. There were no symptoms before death pointing to cerebral disease. Verily, it takes a long time for the profession to learn some things.

— Chicago is in disgrace again. A poor woman, with a baby in her arms, is turned out upon the street because she has measles, supposed by the brutal people with whom she is stopping to be small-pox. She seeks admission to every hospital in the city, and is refused. Then the commissioner of health provides quarters for her in his office at the city hall, and feeds her at his own expense. Two days later a man is reported dying under a sidewalk, having been ejected from his boarding-house because he was sick. His disease is found to be measles, and to keep him off from the street and from death by starvation he is provided quarters in the commissioner's office, and at the expense of that official's private purse. There is no hospital, public or private, that will accept such cases, and the city has provided no means for taking care of them in any way. Is it any wonder that a certain official of the health department characterized this as a disgrace to the city in terms too strong for the papers to print without the use of dashes?

— Another case of death from chloroform, used as an anæsthetic, has occurred in this city. The doctor who was making the operation (a minor amputation for a crushing injury) and the lay friend who was giving the chloroform were exonerated from all blame by the coroner's jury, because it was found that the patient had valvular disease of the heart and fatty degeneration of the muscular substance of the heart, although he was a man less than thirty-five years old. It was in evidence that ether had first been used, and that the reason of the substitution of chloroform was the fact that anæsthesia could not be (or was not) induced by the ether. But very little ether was administered, and for a very brief period. The testimony was strong that only a very small portion of chloroform was used, and that it had been used cautiously.

MEDICO-LEGAL.

— Supreme Court of Illinois. (1.) A voluntary conveyance made by one actually competent to execute it will not be set aside by a court of equity, there being no fraud, mistake, or undue influence shown. (2.) Neither permanent nor transient mental infirmity, not amounting to an inability to understand the nature of a transaction, is sufficient to vacate such a conveyance, where there is no undue influence connected therewith.

Supreme Court of Pennsylvania. (1.) If parents suffer a child of tender years to run at large without a protector in a city traversed constantly by cars and other vehicles, they are guilty of such negligence as will preclude them from any recovery for any injury to the child resulting therefrom. (2.) A child seven years of age was permitted and encouraged by his surviving parent, his mother, to supply persons on passenger cars with water for reward, and thereby met with an accident by which he was killed. *Held*, the parent could not recover.

Miscellany.

THE ADMISSION OF WOMEN TO THE MASSACHUSETTS MEDICAL SOCIETY.

MR. EDITOR,— Now that the annual meeting of the Massachusetts Medical Society is approaching it is time to ask the attention of members to a most important subject, on which, no doubt, they will be called upon to vote,— the admission of women. I say that they no doubt will be called upon to vote, because under the present grave doubt of the legality of the action of the council in attempting to settle the matter, we cannot believe that any feeling of pique will deter that body from the course which is clearly its duty, namely, asking for the concurrent vote of the society at large.

There is nothing to be said to the rabid woman sympathizers; they are past argument. The class that is addressed is a large and influential one, for it holds the balance of power. It consists of those who have not very fixed ideas on the matter. This class is always in danger of being influenced by the more radical, and consequently noisy, party, and therefore advantage is taken of the lull before the storm to suggest a few points for serious consideration.

First of all, I would beg these gentlemen to remember that their action will be most important. They do not meet the question fairly if they say, "We don't believe in this, but the controversy is getting really too tiresome; let the experiment be tried, and give us peace." Those who speak in this way must be very careless of the interests and honor of the society. If the experiment fails, what then? How is the harm once done to be undone? The very fact that the proposed step is an experiment should make it unworthy even of the consideration of the Massachusetts Medical Society. "*Fiat experimentum in corpore vili.*" It is not for us. The great influence of the Massachusetts Medical Society should be thrown on the side of that only which is known to be good. That many young women, who might be better employed, are studying medicine is true, but there is no evidence that more than a very few of the best reach the average of male practitioners. It is true that there are some most estimable ladies of good attainments practicing medicine among us, but it is not unjust to ask these to wait without official recognition till they reach at least a respectable number. That a great society should modify its policy for the feelings of an utterly insignificant group of individuals is contrary to common sense. The burden of proof is on the women; when they can present a class deserving recognition they will be recognized. To do it sooner is to do a grievous injury to the society.

We are confident that a wise conservatism will begin to assert itself. Thinking members, who know something of the inside history of the proposed medical bill, which happily was killed in committee by the late legislature, blush for the discredit brought on the regular profession by the intrigues to which the manipulators of the bill descended. It was managed by an irresponsible body,— irresponsible at least to our society,— and never had the approval of the profession. But though it has failed, its evil is not yet over. Why do we allude to this painful subject? Because if the mass of the profession had but taken the trouble to speak, the plan would have been nipped in the bud, and this disgrace spared the society.

Let us not commit this mistake again. Let us be firm that the society shall not be driven into hasty action. Let us make no change till we are sure that it is needed, and that it is needed now.

A FELLOW.

RECTO-VAGINAL FISTULA CURED WITHOUT OPERATION.

BY IRA BROWN, M. D., WELLS RIVER, VT.

SEPTEMBER 21, 1878, I was called to see J. L., a maiden lady about forty-eight years of age. She had been an invalid most of the time for twenty-five years, and now complained of frequent micturition, the water having a bad odor and containing a gritty dark sediment.

On making a digital examination I found a recto-vaginal fistula twelve lines in length, with rounded and thickened edges, showing that it had existed for some time.

Not having the means at hand nor any one to assist in an operation, after introducing the speculum I made a thorough application to the edges of the fistula of a strong solution of carbolic acid, four parts of the acid to one part alcohol. This done the patient was di-

rected to remain in bed, and to use no means to move the bowels until I saw her again.

September 25th, four days after the first visit, she reported herself better, her water having lost its bad odor and containing no sediment.

She was again seen September 29th, eight days from first visit, when an examination showed the fistula nicely closed in its whole extent.

October 9th, eighteen days from the first visit, a careful examination failed to show any trace of the fistula.

In July following, I learned that she had remained well. I would here venture the opinion that carbolic acid may be used in most cases instead of the knife in preparing surfaces to be united with sutures.

JOHNS HOPKINS UNIVERSITY.

WE find this interesting information in the *New York Tribune*: "In accordance with the suggestion of Dr. W. K. Brooks, associate professor of biology, who has recently visited the town of Beaufort, N. C., the trustees of the Johns Hopkins University have chosen that town as the place for the third session of the Marine Zoological Laboratory of the University. As heretofore, Dr. Brooks will be the director of the laboratory, which retains the name of the Chesapeake Zoological Laboratory. It has been voted to try Beaufort for one year before putting up a permanent building for sea-side work. This year's session will extend from April 22d to September 1st. A house has been rented close to the water for a party of six investigators besides the director. The laboratory will be equipped with boats, nets, dredges, aquaria, books, microscopes, and all the necessary appliances for collecting and studying marine animals and plants. It will also be furnished with a steam launch, which is now building at the yard of Herrescott, in Bristol, R. I., for dredging and surface collecting. Such applicants for admission as may be approved by the director will be charged a registration fee of \$15 for the use of the laboratory and outfit, and the scientific advice and assistance of the director. No lectures will be given. Lodging and board will not be provided by the university, as the town of Beaufort affords ample accommodations; but the director will secure accommodations in advance for those who wish him to do so. Dr. Brooks is now at Beaufort.

The situation of the town, just opposite to and only two miles distant from the straits which connect Pamlico Sound with the open ocean, is considered a very advantageous and salubrious one. In years past, Louis Agassiz, Professor A. S. Packard, Professor E. S. Morse, and others have prosecuted successful researches there.

From time to time, as material has accumulated, the university has published under the editorship of Dr. H. Newell Martin, the head of the biological department, collections of original papers entitled *Studies from the Biological Laboratory of the Johns Hopkins University*. The first volume is just completed; Dr. W. K. Brooks's papers on "The Development of the American Oyster and on The Acquisition and Loss of a Food-Yolk in Molluscan Eggs constituting Part IV. The volume contains 519 pages, 40 plates, and is divided into four parts.

In future the publication will appear under the joint editorship of Professor Martin and Dr. Brooks; the

former taking charge of the physiological and the latter of the morphological papers. Parts will be published as sufficient material accumulates.

Three other journals are conducted by professors of the University. *The American Journal of Mathematics*, pure and applied, has for its editor-in-chief J. J. Sylvester, head of the mathematical department. *The American Chemical Journal* is edited by Ira Remsen, head of the chemical department. B. L. Gildersleeve, professor of Greek and head of the philological department, has recently issued the first number of the *American Journal of Philology*. Each of the other journals has completed its first volume.

There has been recently organized a Baltimore Naturalists' Field Club, with its headquarters at the university. Professor Martin is its president. The object of the club is to study the fauna, flora, and geology of the neighborhood of Baltimore, to make collections illustrative of the above subjects, and to accumulate data for an accurate map of the region, which shall be of use to all students of its natural history. Sections have been organized in botany, vertebrate land animals, invertebrate land animals, aquatic animals, geology, and physical geography. It is proposed to make weekly excursions on Saturdays, and to hold monthly meetings at the university. As there is not so much as a list of plants of Baltimore city and county, the club seems to have a promising field for its operations.

PROSTITUTION AND DEPOPULATION.

THE following is from the *American Medical Bi-Weekly*:—

"According to a correspondent of one of the London journals, it appears that a deputation of members of both sexes from the reform societies of Switzerland, Belgium, England, etc., visited Paris during the early part of the year 1878, with the view of putting an end to legal prostitution in France; but it seems from their discoveries that their mission was an absolutely hopeless one. While this committee was in Paris the whole subject was discussed by the Anthropological Society of that city, for the purpose of determining what was really the effect of prostitution on both the population and depopulation of different countries. Dr. Desprès showed that in Belgium, where the legal organization of prostitution is most complete, marriage is continually becoming more rare, and that the system of national concubinage and prostitution thereby resulting is rapidly depopulating that country. It was demonstrated during the debate that women living under the marriage relation produce more children than those living in a condition of concubinage; while those living in this latter condition are more fruitful than regular prostitutes. It was further made manifest that while concubines miscarry during the first or second month, as the result usually of artificial causes, prostitutes miscarry during the first month as the direct effect of the life which they lead and the immediate and constant strain upon the generative organs. It seems that this miscarriage among professional prostitutes is almost invariable; that they themselves are never aware of conception, as it does not proceed far enough, but learn the fact either from a profuse and untimely flow, or from the examination to which they are periodically subjected. While, therefore, conception is rare among regular prostitutes, miscarriage is almost the

invariable rule when conception occasionally takes place. So that the result of both this general concubinage and prostitution is, as far as population is concerned, a practical sterility, and in countries where concubinage and prostitution are generally tolerated an increasing depopulation is now the result. These facts at first seem to constitute only social problems, but it is manifest to the careful thinker that they underlie the very basis of national prosperity and growth; for even if scientists agree or disagree as to the advisability or necessity of legalizing prostitution, with the view of checking disease, both immediate and prospective, there is far beyond this question the ultimate one of the effect of prostitution in the depopulation and destruction of a nation. It would seem, too, that if prostitution be made safe and disease be not relatively but actually checked, that public sentiment would thus give an implied support to prostitution:

that it would largely increase, and that the results of such a system must be fatal to national increase. It is very true that the disciples of Malthus see in the effects of prostitution a practical removal of their fears in regard to over-population; but it is manifest that this apparent remedy (for over-population) has precisely the same effects as would the condition (over-population) for which the remedy is applied; for it makes practically but little difference in the problem whether, according to Malthus, depopulation would occur as the result of over-crowding or the result of general prostitution. It appears that in France the normal increase of population is being diminished at the rate of 500,000 every year. This appalling fact, striking ultimately at the very existence of the French nation, seems, according to Gallic philosophy, to be not one of national extinction, prospectively, but of national prosperity."

REPORTED MORTALITY FOR THE WEEK ENDING MAY 8, 1880.

Deaths reported, 2407; 972 under five years of age: principal "zymotic" diseases (small-pox, measles, diphtheria and croup, diarrheal diseases, whooping-cough, erysipelas, and fevers) 382, lung diseases 378, consumption 351, diphtheria and croup 106, measles 58, scarlet fever 54, diarrheal diseases 51, typhoid fever 35, malarial fevers 20, whooping-cough 20, cerebro-spinal meningitis 15, erysipelas 11, small-pox six, typhus fever three. From measles, New York 25, Brooklyn and Cincinnati seven, Chicago five, Pittsburgh four, Philadelphia three, St. Louis and Salem two, Providence, Lowell, and Fall River one. From malarial fevers, New York seven, Brooklyn five,

Chicago, St. Louis, and New Haven two, Baltimore and Malden one. From whooping-cough, New York five, Cincinnati four, Philadelphia, Chicago, and Pittsburgh two, Brooklyn, St. Louis, Boston, District of Columbia, and Charleston one. From cerebro-spinal meningitis, New York four, Philadelphia three, Chicago and St. Louis two, Baltimore, District of Columbia, Worcester, and Holyoke one. From erysipelas, New York, Philadelphia, Brooklyn, St. Louis, and Boston two, Salem one. From small-pox, Philadelphia, Chicago, and Fall River two. From typhus fever, Baltimore two, Chicago one. In addition, New Orleans reports consumption 23, lung diseases 10, diar-

rheal diseases eight, measles seven, malarial fevers six, whooping-cough four, scarlet fever two, cerebro-spinal meningitis, diphtheria, and typhoid fever one each, total deaths not given; and Nashville reports consumption three, whooping-cough and typhoid fever two each, total deaths not given.

Eighty-two cases of measles, 41 of scarlet fever, 28 of diphtheria, and one of typhoid fever were reported in Brooklyn; small-pox nine, in Chicago; diphtheria 19, scarlet fever 12, in Boston; diphtheria 17, scarlet fever 10, in Milwaukee; scarlet fever 10, diphtheria eight, measles two, cerebro-spinal meningitis one, erysipelas one, typhoid fever one, in Providence; diphtheria six, in Cambridge; small-pox nine, in Fall River; scarlet fever seven, in New Bedford.

The total number of deaths reported and the number of deaths under five are about the average. One death from sun-stroke is reported from Chicago.

In 38 cities and towns of Massachusetts, with an estimated population of 1,006,260 (population of the State about 1,690,000), the total death-rate was 19.81 against 20.50 and 19.82 for the previous two weeks.

For the week ending April 17th, in 149 German cities and towns, with an estimated population of 7,632,325, the death-rate was 29.9 against 28.1 and 28.6 for the two previous weeks. Deaths reported, 5785; 2080 under five: pulmonary consump-

tion 651, acute diseases of the respiratory organs 608, diphtheria and croup 130, measles and *rubeola* 80, scarlet fever 70, whooping-cough 64, typhoid fever 55, purpura fever 18, typhus (Dantzig, Thorn five, Brannschweig) eight, small-pox one. The death-rates ranged from 17.7 in Karlsruhe to 52.4 in Munich; Königsberg 40.6; Breslau 29.8; Munich 52.4; Dresden 29.8; Berlin 29.8; Leipzig 30; Hamburg 27.2; Hanover 23.5; Bremen 24.8; Cologne 25; Frankfurt 30.1. For the same week, Vienna 35.5; Paris 31.4.

For the week ending April 24th, in the 20 English cities, with an estimated population of 7,499,468, the death-rate was 21.3. Deaths reported, 3062: acute diseases of the respiratory organs 295, whooping-cough 132, measles 108, scarlet fever 107, fever 47, diarrhoea 33, small-pox 15, diphtheria 13. The death-rates ranged from 14 in Portsmouth and Leicester to 32 in Plymouth; London 20.2; Bristol 19.6; Birmingham 20.9; Liverpool 23.7; Manchester 23.6. In Edinburgh 24, Glasgow 25, Dublin 36.

In the 20 chief towns in Switzerland, population 445,790, there were 39 deaths from acute diseases of the respiratory organs, diarrhoeal diseases 16, diphtheria and croup 10, scarlet fever seven, whooping-cough four, typhoid fever four. Death-rate of Geneva 27.3; of Zurich 27; Basle 29.6; Berne 29.5.

The meteorological record for the week in Boston was as follows:—

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U. S. ARMY, FROM MAY 8, 1880, TO MAY 14, 1880.

KING, WILLIAM S., Lieutenant-colonel and surgeon. His leave of absence still further extended six months on account of sickness. S. O. 101, A. G. O., May 7, 1880.

WOODWARD, J. J., major and surgeon. To proceed to Europe under special instructions to be communicated by the surgeon-general. After completion of the duties assigned him, to return to his station in Washington, D. C. S. O. 105, A. G. O., May 12, 1880.

LIST OF CHANGES IN THE MEDICAL CORPS OF THE NAVY FROM MAY 1, 1880, TO MAY 15, 1880.

SURGEON C. H. WHITE from the Naval Hospital, Mare Island, Cal., to the U. S. S. Lackawanna.

Surgeon G. A. BACOT from the U. S. S. Tascara to the hospital, Mare Island.

Assistant Surgeon GEORGE ARTHUR from the Naval Hospital, Norfolk, to the iron clads, Brandon, Va.

Passed Assistant Surgeon R. WHITING from the U. S. iron clads, Brandon, Va., and granted sick leave.

Passed Assistant Surgeon P. FITZSIMMONS granted leave for three months.

Passed Assistant Surgeon W. R. DE BOSE detached from the receiving ship, New York, and granted sick leave.

Assistant Surgeon R. ASHBURIDGE ordered to the receiving ship, New York.

Passed Assistant Surgeon GEORGE P. LUMSDEN ordered to the Naval Academy, Annapolis, Md.

FRACTURES AT THE RHODE ISLAND HOSPITAL.

BY EDWARD T. CASWELL, M. D., PROVIDENCE, R. I.

THE Rhode Island Hospital was opened for the admission of patients on October 1, 1868. When it had completed the first ten years of its existence, I thought I would collect and publish some statistics of what had been done during those years by my colleagues and myself. The laborious undertaking of going over the hospital records and other engrossing duties have postponed the publication of this, which may be considered a first contribution, until this late day. I greatly regret the inaccuracy of the records, and their failure in a large majority of cases to supply precisely the most important information, as, for example, the side of the body which sustained injury, and the length of limb in fractures of the lower extremity, both on admission and discharge. Nothing can be more unsatisfactory or more worthless for all purposes of comparison than to have the result of treatment of a case of fracture entered as "good," or "well," or "recovered." But such, I regret to say, has frequently been the entry. In spite of these failures, however, I venture to present the following tables, hoping that they may not be without some interest. They represent all the fractures admitted to the wards of the hospital for ten years; they do not include fractures treated in the outpatient department.

I find recorded 185 cases of fracture occurring in 167 persons. There have been 152 cases of single fracture, 12 in which there were two different fractures, and 3 in which there were three different fractures. Each of these are entered under their respective sections. Of course this does not apply to the case of fractured ribs, where one, two, or more may be broken, nor to that of a leg or fore-arm where both bones are broken. Just as these sheets were nearly ready for the press, I find that one case of fracture of both thighs and one of compound fracture of both legs have each been entered as one fracture. So that there are actually 187 cases of fracture in 167 individuals. Fractures of the foot and hand have not been included. A separate list has been added of injuries rapidly fatal, although they have been included in their appropriate sections. I have also appended the statistics of the very small number of dislocations that have been admitted to the wards of the hospital for the same period.

From the summary we see that of all the fractures nearly one half were fractures of the lower extremity, and of these more than half were fractures of the leg. Of the latter more than half were fractures of both bones. According to frequency, these fractures would be arranged as follows: Leg, thigh, fore-arm, arm, ribs, clavicle, skull, vertebrae, scapula. No fractures of the pelvis are recorded. The relative frequency of the fractures of the different sides of the body will be referred to further on.

MORTALITY.

Of the 167 individuals who were admitted for fractures, 25 died, or 15 per cent. Of these, 15 died in the course of twenty-four hours, and of this number, 11 were caused by railroad accidents. These deaths, although not so stated in the record, are without doubt

to be ascribed to shock and the loss of blood attendant upon the accidents. Of the remaining 10 cases, 2 died from intemperance, 1 from pneumonia following a fracture of the ribs, 1 from pyæmia, 1 from convulsions on the third day after a compound fracture of the skull, 1 suddenly, without cause ascertained, on the second day after a simple fracture of the thigh; and in the remaining 4 cases death ensued from the injury, at intervals varying from thirty-six hours to six days, as follows: (1) vertebra and compound fracture of tibia, six days; (2) vertebra, three days; (3) skull, three days; (4) base of skull, thirty-six hours.

REVIEW OF FRACTURES IN GROUPS.

I now propose to pass in review the different groups of fracture, stating such points as are the most salient in the tables.

CRANIUM.

There were ten cases, all in males, of which seven were compound. All died except two of the latter. Of these, one was a compound comminuted fracture of the left orbital region, accompanied with the loss of brain substance. The accident happened six weeks before his admission to the hospital, and was occasioned by a heavy piece of machinery falling upon him while erecting the engine at the pumping station at Sockanossett. Pieces of bone were removed at the time. He remained in the hospital one hundred and fifty-two days, and left entirely restored, with the loss of the left eye. He has continued to be perfectly well, and still fills the post of engineer at the station. The other successful case was caused by a pistol-shot in the frontal and parietal region. The trephine was used, the bullet extracted, and the patient left the hospital in twenty-three days.

MAXILLÆ.

There were nine cases, all in males. One died from delirium tremens. One was a compound fracture of both bones, and left the hospital at the expiration of twenty-six days. Of the seven simple cases, the average residence was twenty-six days. Wiring the teeth, pasteboard and gutta-percha splints, were the methods of treatment.

RIBS.

There were thirteen cases, of which ten were males and three females. Of these three died, two from other serious injuries, and one from pneumonia, in twenty days. Of the remaining ten, the average residence in the hospital was thirty-three days. In seven cases more than one rib was broken. The majority of cases were treated by strips of adhesive plaster.

SCAPULÆ.

Of only four cases recorded, all of males, one died from fracture of the skull. In two cases the left is specified. The average residence of three was thirty-three days.

CLAVICLE.

There were twelve cases, of which eleven were males and one female. Of these, one died from other serious injuries, and one left the hospital four days after admission. The average residence of the remaining ten was thirty-six days. Of these cases, five were on the right side, four on the left, and three not given. In eight the fracture was in the outer third, in two, in the middle, one in the inner third, and one not stated. The treatment varied, the larger number being treated by the axillary pad and bandage; Sayre's method, with adhesive strips, was used in some cases.

FRACTURES OF THE HEAD.

Sex, Age, Nativity.	Date of Admission.	Cause.	Definition of Fracture.	Treatment.	Date of Discharge.	Result.	Remarks.
I. CRANIUM.							
<i>Simple.</i>							
1 M. 27	October 22, 1872.	Railroad accident.	Base.		October 26, 1872.	Died.	
2 M. 27	September 7, 1874.	Railroad accident.	Left supra-orbital arch.		December 1, 1874.	Died.	
3 M.	September 24, 1875.	Thrown fr. overboard.			September 25, 1875.		Thirty-six hours after admission. Died in hospital next morning.
1 M. 59	April 2, 1875.	Brick falling.	"No depression."	<i>Compound.</i>	April 5, 1875.	Died.	
2 M. 30	October 16, 1875.	Fall from house.	Comminuted.		October 16, 1875.	Died.	
3 M. 45	October 24, 1875.	Fall from house on him.	Comminuted, left frontal bone.		March 30, 1876.	Good.	Admission. Attended with hemorrhage and loss of brain, loss of left eye, and fracture orbital plate. Comminuted admission. Died in six hours.
4 M. 33	June 15, 1876.	Left ear, surface depressed.			June 15, 1876.	Died.	
5 M. 38	August 7, 1876.	Gun-shot, antistial.	Frontal and parietal.		August 20, 1876.	Good.	Bullet lodged in bone. Accident two weeks before admission.
6 M. 13	May 16, 1875.	Fall from third story.	Depressed behind left ear.		May 16, 1875.	Died on admission.	Compound fracture right radius, fracture left ulna and fracture left tibia and fibula.
7 M. 45	July 15, 1878.	Mining accident.	Depressed.		July 15, 1878.	Died 8 hours after admission.	Fracture left acromion, comminuted fracture left tibia.
II. SUPERIOR AND INFERIOR MAXILLA (COMPOUND).							
1 M. 35	July 18, 1877.	Struck by deriek.	Super, entire length barrel-nail in median line; finger could be laid in cavity. Infer, left of symphysis.		August 13, 1875.	Good.	Fracture of clavicle, No 10.
III. INFERIOR MAXILLA.							
(1) In front of symphysis and teeth on left side wired; (2) In front of angle, right side, pointed bandage.							
1 M. 26	November 4, 1878.	Blow.	Neer symphysis.		December 8, 1878.	Good.	Small spicula of bone discharged from an abscess which formed on inner surface, right side.
2 M. 27	August 15, 1879.	Run over.	Alveolar process not ruptured.		August 21, 1879.	Died.	Delirium tremens.
3 M.	October 2, 1874.		Process not ruptured.		October 21, 1871.	Good.	
4 M. 24	February 1, 1872.	Blow.	At symphysis.		February 27, 1872.	Good.	
5 M. 39	July 16, 1873.	Struck by lawer.	Gutta-percha splint; teeth Gutta-percha splint.		August 8, 1873.	Good.	
6 M. 8	March 6, 1874.	Fall.	Each side median line.		March 26, 1874.	Good.	Removed by friends. Fracture left femur, No. 9.
7 M. 42	April 20, 1877.	Fall.	Between canine and first bicupid; not oblique.		May 28, 1877.	Good.	Small pieces of bone discharged May 23d and 24th from abscess on inside over seat of fracture.
8 M. 50	July 15, 1878.	Blow.	Right, half an inch anterior to angle.		August 8, 1878.	Union.	Discharged because he refused to submit to wiring fragments.

FRACTURES OF THE VERTEBRÆ.

1 M. 28	French Canadian	September 15, 1873.	Struck by a beam falling.	Spinous process of one of lower dorsal wanting.	September 21, 1873.	Died.	Paralysis of lower extremities and bladder. Compound fracture of tibia and fibula. (No. 1.)
2 M. 58	American.	October 21, 1879.	Falling on back.	Sacrum.	October 21, 1879.	Died.	Shortly after entrance, twenty-four hours after accident.
3 M. 31	English.	February 22, 1871.	Railroad accident.	Fourth cervical, also dislocated.	February 22, 1871.	Died.	
4 M. 21	Irish.	April 21, 1875.	Railroad accident.	Eleventh dorsal, vertebra, and dislocation of teeth.	April 19, 1876.	Died.	Fracture of ribs and acromion end of clavicle.
5 M. 35	American.	January 11, 1873.	Struck by heavy stone.	Last dorsal and first lumbar.	January 11, 1873.	Died.	In an hour after admission.
6 M. 42	English.	January 16, 1878.	Struck by falling timber.		September 11, 1878.	Improved.	Had paralysis of lower extremities and bed sores. Later healed, and able to walk well when discharged.

FRACTURES OF THE RIBS.

1 M. 19	American.	February 15, 1872.	Railroad accident.	Four lower, near vertebra.	February 17, 1872.	Died in 1 hour.	Compound fracture of leg.
2 F. 69	Irish.	April 19, 1873.	Railroad accident.	End and bandage.	April 19, 1873.	Good.	Pneumonia. Fracture of tibia and fibula. (No. 8.)
3 M. 46	Fr. Canadian.	August 20, 1873.	Run over.	Sixth and seventh, near acromion.	September 3, 1873.	Good.	Accident two weeks before admission, followed by cough and expectoration.
4 M. 40	Irish.	September 20, 1873.	Stamped upon.	Eighth, ninth, and tenth. Broad swathe.	October 23, 1873.	Good.	

5 M.	50 Irish.	January 9, 1874.	Fall.	Eight and a half.	Adhesive strips	Good.	Died in 9 hours.	Dislocation teeth, dorsal vertebrae. Fracture of clavicle and acromion end of clavicle.
6 M.	24 Irish.	April 20, 1872.	Railroad accident.			Died in 3 hrs.		
7 M.	42 Irish.	May 6, 1875.	Fall.	Seventh.	Adhesive plaster.	Good.		
8 M.	43 Scotch.	October 25, 1875.	Fall.	Seventh.	Adhesive plaster.	Good.		
9 M.	21 Irish.	October 25, 1875.	Fall.	Eighth.	Adhesive plaster and band.	Good.		
10 M.	62 Irish.	January 13, 1877.	Fall.	Ninth.	Adhesive plaster.	Good.		
11 F.	63 English.	July 13, 1877.	Fall.	Right side, two ribs.	Adhesive plaster.	Good.		Elipsoid. Complicated with fracture of tibia and fibula. No. 13.
12 F.	40 Irish.	January 16, 1878.	Struck by fall. Umb.	Fourth, under sternum.	Adhesive strips.	Good.		
13 M.	25 American.	March 5, 1878.	Fall.	Sixth, three or four inches from acromion.	Adhesive strips.	Good.		

FRACTURES OF THE SCAPULA.

1 M.	50 Irish.	August 23, 1871.	Blow.	Neck.	Pad in axilla, arm across chest.	Unrelieved.		Accident two months prior to admission. When discharged, no union.
2 M.	44 American.	April 15, 1872.	Fall.	Neck.	Pad in axilla and sling band.	Good.		Charged at his own request.
3 M.	49 Irish.	June 15, 1875.	Kick of horse.	Left.	Adhesive plaster, Sayre's method.	Good.		Fractured clavicle. No. 5.
4 M.	45 Irish.	July 15, 1878.	Mining accident.	Left acromion process.		Died 8 1/2 hours after admission.		Depressed fracture of skull. Comminuted fracture of left tibia.

FRACTURES OF THE CLAVICLE.

1 M.	30 Irish.	September 11, 1871.	Fall.	Right, two and a half inches from acromion.	Pad in axilla and bandage.	Good.		February 27th, large callus.
2 M.	25 Irish.	April 19, 1873.	Railroad accident.	Left, outer third.	Pad in axilla and over fract.	Good.		When discharged, ends overlapped one half to three fourths of an inch. Sculp wound and loss of two
3 M.	40 Irish.	March 5, 1874.	Jumped.	Left, middle, two fractures.	Adhesive plaster.	Good.		Fracture of ribs and eleventh dorsal vertebra, and
4 F.	38 English.	March 20, 1874.	Railroad accident.	Left, middle, two fractures.	Bandage.	Good.		dislocation of the teeth.
5 M.	24 Irish.	April 20, 1875.	Railroad accident.	Acromion end.	Pad in axilla and bandage.	Died in 9 hrs.		Fracture of scapula. No. 3.
6 M.	49 Irish.	June 15, 1875.	Kick of horse.	Left, acromion end.	Adhesive plaster (Sayre's).	Good.		Fracture of superior and inferior maxilla. No. 1.
7 M.	25 Irish.	October 29, 1875.	Earth caved in.	Right, inner third.	Bandage.	Good.		Left the hospital.
8 M.	39 Irish.	November 23, 1875.	Fall.	Right, two in. from acromion.	Bandage.	Good.		
9 M.	38 Irish.	February 21, 1877.	Fall.	Right, outer third.	Pad in axilla, bandage, arm	Good.		
10 M.	35 Irish.	July 18, 1877.	Struck by derrick.	Right, junction middle and outer third.	Pad in axilla and bandage.	Good.		
11 M.	38 Irish.	July 21, 1877.	Blow.	Near outer extremity.	Adhesive plaster and band.	Good.		
12 M.	30 Irish.	January 3, 1878.	Jumped.	Left, acromion end.	Adhesive strips (Sayre's).	Good.		

FRACTURES OF THE UPPER EXTREMITY.

1 M.	60 German.	June 19, 1869.	Fall.	Middle and lower thirds.	No treatment.	Died.		Effects of intemperance.
2 M.	29 German.	January 10, 1870.	Wrench.	Left, just above middle, transverse.	External and internal angular splints.	Slight deformity.		Union firm. Motion imperfect.
3 F.	64 Irish.	June 30, 1871.	Fall.	Just below surgical neck.	Gibber splints, splint and shoulder cap.	Discharged by request.		
4 M.	40 Irish.	September 30, 1871.	Machinery accident.	Upper third.	Internal angular splint.	Good.		Fracture occurred one week before admission.
5 F.	11 American.	January 29, 1872.	Fall.	Lower and middle thirds.	Internal angular and external splints.	Good.		Fracture a little more than one week prior to admission.
6 M.	37 Irish.	June 7, 1872.	Fall.	Left, two in. above elbow.	Plaster Paris at angle.	Good.		Seven-pound weight, November 5th, to hand to overcome flexion. November 10th, ten pounds.
7 M.	68 American.	February 25, 1873.	Fall.	External condyle, involution.	Internal angular splint.	Good.		Pyemia. Abscesses, both elbows.
8 M.	15 Irish.	September 24, 1873.	Fall on elbow.	Left, internal condyle.	Internal angular splint.	Died.		
9 M.	25 Colored.	August 17, 1874.	Fall from scaffold.	Left, internal condyle.	Internal angular splint.	Good.		Motion almost perfect. Accident four days before admission.
10 M.	37 American.	September 3, 1874.	Fall.	Internal condyle (?). No crepitus.	Rectangular splint.	Good.		Fracture of ulna and radius two inches from wrist.
11 M.	21 Irish.	November 17, 1874.	Fall.	Left, internal condyle.	Internal angular splint.	Good.		
12 M.	31 Irish.	January 5, 1875.	Fall.	Right, internal condyle.	Ant. post. and lat. splints.	Good.		
13 M.	31 English.	June 11, 1875.	Machinery accident.	Right, upper third.	Internal splint.	Good.		

FRACTURES OF THE UPPER EXTREMITY (continued).

Sex.	Age.	Nativity.	Date of Admission.	Cause.	Detail of Fracture.	Treatment.	Date of Discharge.	Result.	Remarks.
14	M.	American.	November 18, 1875.	Fall.	External condyle.	External angular splint, Int. below elbow.	January 2, 1876.	Good.	Discharged for drunkenness before treatment ended.
15	F.	42 Irish.	December 9, 1875.		Lower third.	Plaster Paris, January 9th, Int. and external.	February 7, 1876.	Good.	Fracture of ulna "above coronoid process."
16	F.	70 English.	January 1, 1876.	Fall.	Left. High up.	Plaster Paris.	February 26, 1876.	Good.	
17	M.	42 French Canadian.	June 8, 1876.	Fall.	Left. External and internal condyles.	Internal angular splint.	July 8, 1876.	Good.	
ELBOW-JOINT.									
1	M.	23 American.	January 25, 1879.	Railroad accident.	Left, compound.	Resection.	June 15, 1879.	Wound nearly healed.	Left without permission. Said to have been amputated subsequently.
2	M.	28 German.	July 5, 1876.	Railroad accident.	Right, comminuted.	Internal ang. splint. July 12th, straight splint.	February 2, 1877.	Good.	Compound comminuted fracture of right tibia and fibula.
RADIUS AND ULNA.									
1	M.	8 American.	December 12, 1870.	Fall.	A little above wrist.	Ant. and post. splints.	January 3, 1871.	Good.	Lacerated wound wrist.
2	M.	27 American.	July 7, 1871.	Machinery accident.	Radius, lower part.	Bond's splint.	May 15, 1871.	Good.	
3	M.	14 American.	December 17, 1873.	Fall.	Upper part.	Straight splint, place Paris.	January 15, 1874.	Good.	Fracture right humerus (No. 12). Discharged for drunkenness before treatment ended.
4	M.	34 English.	June 14, 1875.	Fall.	Right, two inches above wrist.	Light side splints.	July 11, 1875.	Good.	Union and position good.
5	F.	15 Irish.	January 12, 1878.	Fall.	Left, middle and lower thirds.	Ant. and post. splints.	February 12, 1878.	Good.	
6	M.	13 Pole.	June 4, 1878.	Machinery accident.	Just below elbow.	Straight ant. splint.	August 17, 1878.	Good.	
7	M.	19 Irish.	September 23, 1878.	Machinery accident.	Just below elbow.	Ant. and post. splints.	October 10, 1878.	Good.	Discharged at request.
RADIUS.									
1	M.	12 American.	October 19, 1878.	Fall on feet.	Right lower end, carpus driven.	Ant. and post. splints.	October 25, 1878.	Good.	
2	M.	52 American.	November 5, 1878.	Fall.	Left lower end.	Ant. and post. splints.	December 18, 1878.	Good.	
3	F.	34 Irish.	February 10, 1872.	Fall.	Colles.	Bond's splint, short dorsal.	March 27, 1872.	Good.	
4	F.	65 Irish.	February 22, 1876.	Fall from window.	Right, Colles.	Post. slanted splint.	March 28, 1876.	Good.	
5	M.	62 Irish.	May 1, 1877.	Fall.	Right, Colles.	Post. slanted splint.	May 10, 1877.	Good.	
6	M.	45 Nova Scotian.	May 4, 1877.	Fall.	Just below tubercle.	Int. ang. splint.	July 3, 1877.	Good.	Good motion, radius straight.
7	M.	29 Irish.	May 14, 1878.	Blasding accident.	Right, Colles.	Ant. splint.	June 29, 1878.	Good.	Dislocation left wrist. Comp. fract. third finger right hand. Loss of second finger of left hand, with first metacarp. Face and eyes burned with powder.
ULNA.									
1	M.	15 American.	January 13, 1872.	Fall.	Olécranon.	Plaster Paris (straight).	March 20, 1872.	Good.	Abscess over eye, February 20.
2	M.	65 Irish.	July 11, 1872.	Machinery accident.	One inch below elbow.	Bond's splint and short dors.	August 13, 1872.	Good.	No crepitus; preternatural mobility.
3	F.	41 Irish.	April 3, 1872.	Fall from window.	One inch below elbow.	Plaster Paris.	May 9, 1872.	Good.	Accident some time before admission, and treated in out-patient department.
4	M.	33 Irish.	August 7, 1874.	Horse-car.	A little above middle.	Extrem. and intern. splints.	September 8, 1874.	Good.	Fracture condyle hum. (14) "acromion" dislocation hum. (13) "K. radius." Fracture right tibia and fib.
5	M.	29 Portuguese.	November 3, 1875.	Bow.			December 8, 1875.	Good.	
6	M.	39 American.	November 18, 1876.	Fall.	Left, "above coron. process."	Int. splint and ext. ang.	January 12, 1876.	Good.	
7	M.	13 Scotch.	May 10, 1878.	Fall from 3d story.	Left.		May 19, 1878.	Good.	

FRACTURES OF THE LOWER EXTREMITY.

FEMUR.

Simple.

(1.) NECK OF FEMUR.

1	M.	79 Irish.	February 27, 1872.	Fall.	Ext. and count. ext. March 27, Plaster Paris.	June 26, 1872	Unclassed.	One inch shortening; bone no weight.
2	M.	40 Irish.	April 19, 1872.	Fall	Weight and pulleys; removed February 1.	May 7, 1872.	Good.	No shortening; union firm.
3	F.	63 English.	December 19, 1872.	Fall on ice.	Long splint, Jan. 6, weight Buck's ext. April 25, plaster Paris.	March 25, 1873.	Good.	Erysipelas face, March 2.
4	M.	60 Irish.	December 25, 1872.	Fall on ice.				Left without permission.
5	M.	21 American.	April 21, 1873.	Thrown from stage		April 29, 1873		

6 M.	61	English	July 29, 1873.	Fell off a load.	One inch shortening.	Buck's ext., 15 lbs., Aug. 1, 1873. Under Paris.	September 26, 1873.	Shortening $\frac{1}{2}$ inch.	Accident happened a week before admission. Discharge, with one crutch. Load expired on rotation. Left without crutch. Fell again May 29, and re-admitted. See No. 10, below.
7 M.	17	Irish.	November 29, 1873.	Fall.	No shortening; eversion.	Pkt. and counter ext. Bed down. Buck's ext. Re-moved March 8.	March 17, 1874.	Shortening $\frac{3}{4}$ in.	
8 F.	59	Irish.	February 27, 1875.	Fall.	R. Extra capsular.	Buck's apparatus, 7 lbs. Re-moved March 8.	April 24, 1875.	Shortening.	
9 F.	72	Irish.	January 29, 1877.	Fall.	One inch shortening.	Buck's apparatus.	April 28, 1877.	Shortening $10\frac{1}{2}$ inch.	Ligam. union, so that she can move treacher in are fully amenable, removing dressings frequently.
10 F.	75	Irish.	July 9, 1877.	Uninjured.	Uninjured.		July 23, 1877.	Discharged.	
(2.) STAFF.									
1 M.	69	American.	January 8, 1870.	Thrown from wagon.	Left oblique; upper and middle thirds.	Buck's extens.	February 16, 1870.	Union firm.	Removed by friends.
2 F.	65	American.	November 6, 1870.	Fall.	Lower third.	Buck's extens. Doct., February 17, 1871.	April 13, 1871.	Fracture existed two weeks before admission; had not been diagnosed.	
3 M.	28	Irish.	February 10, 1871.	Fall.	Just above knee.	Buck's extens. Thist. Paris, March 12.	April 21, 1871.	Good.	
4 M.	21	American.	November 2, 1871.	Halfroad accident.	Left, comminuted.	Modified Liston's splint.	November 2, 1871.	Good.	
5 M.	11	Irish.	November 13, 1871.	Fall.	Middle third.	Buck's 10 lbs. July 22.	January 11, 1872.	Ideal in few hrs.	Compound fracture right femur. Union firm.
6 M.	9	American.	July 15, 1873.	Run over.	Left, middle, transverse, two inches shortening.	Pkt. with strips.	August 30, 1872.	Good.	
7 M.	69	Irish.	August 21, 1873.	Kneeling down by pole.	Left, middle and upper thirds.	Paris; Oct 7, rem. Oct. 13, long sole splint; ext. and count. extens. No. 13.	February 27, 1874.	Good.	September 13, half inch shortening. October 13, fell and broke thigh again in same place.
8 M.	—	Irish.	October 4, 1873.	Pole fell on him.	Lower third; one and a half inches shortening.	Buck's 20 lbs. October 21.	January 6, 1874.	Good.	Shortening, one inch.
9 M.	37	Nova Scotian.	October 7, 1873.	Staging bridge.	Right, middle, left, half inch shorter.	Buck's 14 lbs.	December 16, 1873.	Good.	Fracture occurred week before admission. November 1, removed by friends. Union firm.
10 M.	8	American.	March 6, 1874.	Fall.	Left, two inches shortening.	Plaster Paris, March 24.	March 26, 1874.	Good.	Removed by friends. Compound fracture lower jaw, November 6. Same case July 1, no shortening.
11 M.	17	Irish.	May 29, 1874.	Fall.	Left, two inches shortening.	Buck's 30 lbs.	August 14, 1874.	Good.	
12 M.	22	Swede.	June 2, 1874.	Fall from staging, three stories.	Right, middle third, one and three quarters inch shortening.	Plaster Paris flannel mould. June 12. Buck's 14 lbs.; July 12, 25 lbs.; Oct. 25, 25 lbs.	August 13, 1874.	Good.	September 12, one inch shortening.
13 M.	37	American.	August 11, 1874.	Fall from staging.	Right, oblique, one inch shortening.	Buck's 25 lbs. Plaster Paris; Sept. 4, Buck's.	October 15, 1874.	Good.	February 22, fell and fractured thigh. March 30, can walk without crutches. Completed on admission. Wound one inch long. Sutured. Bone forcibly replaced. Feb. 8, wound healed.
14 M.	19	Irish.	November 28, 1874.	Heavy plate boiler from fell on him.	Right, middle, and lower third, and half shortening.	Plaster Paris; Jan. 1, plaster Paris.	April 5, 1875.	Good.	September 13, half inch shortening.
15 M.	27	Irish.	July 29, 1875.	Bank fell on him.	Right, lower third.	Buck's 20 lbs. Buck's 14 lbs. Aug. 31, plaster Paris; Sept. 7, Desautel's splint.	November 17, 1875.	Good.	
16 M.	28	Irish.	August 17, 1875.	Fall.	Left, lower third, two inch shortening.	Ant. post., and lat. splints.	August 19, 1875.	Death.	Died suddenly; no cause found.
17 M.	48	English.	July 25, 1876.	Fall.	Right, middle, oblique.	Bay's, etc. Aug. 24, plaster bandage.	November 8, 1875.	Good.	One eighth inch shortening.
18 M.	38	Canadian.	September 21, 1876.	Strung brake; fell fifteen feet.	Right, upper third, oblique.	Doct., etc. Oct. 15, plaster Paris.	November 11, 1876.	Good.	Accident seven days before admission. Oct. 3, three quarters inch shortening. Healed at own request.
19 M.	23	Irish.	December 2, 1876.	Struck by bale of granite.	Little above middle.	Doct., Feb. 4, removed. Buck's 20 lbs. good union; amput. per. foot. June 10, outward curve couple splint retracted. Buck's; retracted in. Buck's; retracted in. Buck's; retracted in. Buck's; retracted in.	March 30, 1877.	Good.	September 11, one third inch shortening.
20 M.	28	Canadian.	April 23, 1877.	Struck by large block granite.	Left, middle third.	11th, plaster and extens. Buck's; Sept. 6, plaster Paris. Buck's 12 lbs. Sept. 28, plaster down to knee. Oct. 22, two thin splints. Buck's 7; eight pounds.	October 6, 1877.	Good.	
21 F.	49	American.	July 7, 1877.	Fall.	Comminuted, lower third.		September 22, 1877.	Good.	September 16, measured, no shortening discovered.
22 M.	21	Irish.	August 15, 1878.	Rock fell on him.	Right, middle third, transverse.		November 6, 1878.	Good.	September 28, half inch shortening, walking well without crutch or cane.
23 F.	59	Irish.	September 21, 1878.	Fall.	Right, just below treacher.		September 24, 1878.	Unhealed.	Recovered by friends.

FRACTURES OF THE LOWER EXTREMITY (continued).

Sex.	Age.	Nativity.	Date of Admission.	Cause.	Definition of Injury.	Treatment.	Date of Discharge.	Result.	Remarks.
FEMUR.									
<i>Compound.</i>									
1	M.	21 American.	November 2, 1871.	Railroad accident.	Right femur; with comminuted fracture left femur.			Died.	In a few hours.
2	M.	12 American.	February 8, 1874.	Railroad accident.	Comminuted left femur.			Died.	Capitulum comminuted right tibia and fib. Two hours after admission.
3	M.	31 Canadian.	April 9, 1874.	Railroad accident.	Comminuted right femur.			Died.	One hour after admission.
4	M.	— Irish.	September 24, 1875.	Railroad accident.	Comminuted left femur; comminuted right femur; fracture fourth finger left hand; lacerated wound left arm from shoulder to wrist.			Died.	Half hour after admission.
PATELLA.									
1	M.	23 American.	September 19, 1874.	Fall.	Scallate.	Fract. eight bandages; adhesive Post-splint and elastic bands.	December 24, 1874.	Good.	Fragments found in good position.
2	M.	30 American.	August 14, 1875.	Fall.	L. transverse.		September 6, 1875.	Good.	
TIBIA AND FIBULA.									
<i>Simple.</i>									
1	M.	35 Colored.	February 22, 1869.	Railroad accident.	Left fib. joint, middle and upper third.	Fract. box; March 29, dextr. plaster Paris splint.	May 22, 1869.	Good.	No apparent shortening.
2	M.	25 Irish.	July 3, 1869.	Machine accident.	L. fibula 4 in. above ankle, comminuted. Fibula 1 in. lower; transverse.	Fract. box; weight and extension 5 lbs.; Aug. 19, dextr. time band.	August 28.	Good.	
3	M.	55 American.	July 22, 1870.	Ducked by falling wall.	L. tibia, fib. and fib., comminuted.	Fract. box and counter-extension.	August 4.	—	Discharged at own request.
4	M.	50 Canadian.	July 27, 1870.	Earth and stones fell on him.	Ununited fracture.	Fract. box; Aug. 16, dextr. time band; Feb. 14, 1871, plaster Paris splint.	October 13.	Good.	Fib. united; fib. considered firm. Accident 48 days prior to admission. Death at own request.
5	F.	49 Irish.	December 25, 1870.	Railroad accident.	Oblique at middle of leg.	Fract. Paris; April 2, dextr. time band.	March 29, 1871.	Good.	
6	M.	65 Irish.	March 4, 1872.	Railroad accident.	Just above ankle.	Fract. box; Aug. 6, dextr. time band.	June 1, 1872.	Good.	
7	M.	29 Irish.	June 24, 1872.	Earth caved in.	Three inches below knee.	Fract. box; April 28, plaster Paris; Oct. 25, plaster Paris band.	September 6, 1872.	Good.	Fracture occurred six weeks before admission; union. Treated with plaster before admission. Fractured five days before admission.
8	F.	69 Irish.	April 19, 1873.	Railroad accident.	Middle; shortening one half inch.	Fract. box; Nov. 21, plaster Paris band.	May 11, 1873.	Died.	Complicated with fractured rib, No. 1. Death from pneumonia.
9	M.	45 Irish.	October 11, 1873.	Earth fell on him.	Just above ankle; shortening one inch.	Fract. box; Oct. 25, plaster Paris band.	December 15, 1873.	Good.	
10	M.	19 German.	November 6, 1873.	Caught by rope.	Just above ankle; shortening one inch.	Fract. box; Dec. 12, gutta-serena; ext. pract. box.	January 12, 1874.	Good.	
11	M.	52 Irish.	December 27, 1873.	Earth caved in.	Near knee; shortening one in.	Extension by wt. 12 lbs.; count. ext. pract. box.	March 24, 1874.	Good.	
12	M.	35 Irish.	January 10, 1874.	Kick.	Four inches above ankle; shortening one inch.	Plaster Paris; Feb. 1, plaster Paris; Feb. 7, new splint.	April 14, 1874.	Good.	
13	M.	29 Irish.	February 24, 1874.	Earth caved in.	Left; middle; shortening three-fourths inch.	Plaster Paris; March 19, removed.	April 4, 1874.	Good.	
14	M.	26 Portuguese.	May 15, 1875.	Jumped off cart.	Right; middle, oblique.	Fract. box; May 24, plaster Paris.	July 24, 1875.	Good.	May 24, three eighties each shortening.
15	F.	63 English.	July 19, 1877.	Fall.	Left; just above joint.	Fract. box.	August 11, 1877.	Good.	Left the hospital. Complicated with fractured ribs. Accident happened eight days before admission. Had delirium tremens.
16	M.	39 Irish.	March 30, 1878.	Fall.	Left; lower third, transverse.	Fract. bandages, Little's method; May 6, pasteboard splints.	May 8, 1878.	Good.	Depressed fracture skull; compound dislocation right radius; fracture left ulna.
17	M.	13 Scotch.	May 10, 1878.	Fall from third story.	Right.		May 16, 1878.	Died on admission.	
<i>Compound.</i>									
1	M.	28 French Can.	September 15, 1869.	Struck by falling beam; back and thighs; bone protruding.	Tibia, joint, upper and middle third; fibula comminuted.	Fract. box.	Sept. 21, 1869.	Death.	Fract. spin. process of one lower dorsal vertebra, No. 1; paralysis lower extremities and bladder.
2	M.	24 American.	January 31, 1872.	Railroad accident.	Near ankle; comminuted.		January 31, 1872.	Death in 3 hours.	Penetrating wound thigh down to trochanter.
3	M.	13 American.	February 17, 1872.	Railroad accident.	Near ankle; comminuted.		February 17, 1872.	Died in 4 hour.	Fract. four lower ribs near vertebral connection.
4	M.	30 Irish.	May 6, 1872.	Barrel fell on leg.		Fract. box; June 4, dextr. band; removed July 1.	September 27, 1872.	Good.	

5 M. 6 M.	21 American. 47 American.	February 8, 1874. June 11, 1874.	Railroad accident. Caught in wagon wheel.	Comminuted. Right lower end comminuted.	One half to one in. lower end of tibia removed; plaster Paris bandage; plaster Paris box; July 15, splints; Aug. 13, 80 spl. swung; Aug. 17, 80 spl. removed.	February 8, 1874. August 24, 1874.	Died in 2 hours. Good.	Compound comminuted fracture left femur. Good union, ankylosis ankle; openings on leg sides nearly healed. July 3, erysipelas in leg August 1, large abscess from heel.
7 M. 8 M.	25 German.	April 25, 1875. July 6, 1875.	Railroad accident. Railroad accident.	Right comminuted. Right comminuted.	Fract. box; Sept. 15, plaster bandage; plaster Paris box; Oct. 5, splint; Oct. 8, plaster bandage; Oct. 9, splint; Oct. 9, plaster bandage; Oct. 9, splint; Oct. 9, plaster bandage.	April 25, 1875. February 2, 1877.	Died in 1½ hours. Good.	Loss of toes of left foot. Small pieces bone worked out. When discharged sinuses still open; could walk on leg.
9 M.	26 Irish.	November 29, 1875.	Struck by a car.	Comminuted.	Plaster Paris; fract. box, congruence.	May 28, 1877.	Good.	Leg dropped off. Bones removed higher up.
10 M. 11 M. 12 M.	24 American. 25 Irish. 12 English.	August 20, 1877. August 2, 1878. August 14, 1878.	Railroad accident. Killed. Jumping.	Comminuted, both legs. Middle third. Middle third; wound in skin down to tibia.	Comminuted splints. Loug post. short external splint; Sept. 24, plaster Paris with fenestra.	August 20, 1877. August 29, 1878. October 11, 1878.	Died in 2 hours. Good.	Removed by friends. Discharged at request. Head bone could be felt.
1 M. 2 M.	20 American. 26 Irish.	June 15, 1871. November 21, 1871.	Railroad accident. Fall.	Right. Lower third.	Simple. Fracture box, short splint; Oct. 3, plaster Paris.	August 24, 1871. March 9, 1872.	Good. Good.	Amputation left leg middle and lower thirds. Plaster Paris removed Oct. 20; slough found not fully healed when discharged.
3 F. 4 M. 5 M.	50 Irish. 34 Irish. 44 English	December 27, 1871. September 17, 1872. September 25, 1872.	Ran over. Run fell on him. Fall.	Oblique lower third. Two inches above ankle.	Jan. 8, plaster Paris. Fract. box; Oct. 9, dextrine Fract. box; Oct. 11, dextrine.	February 27, 1872. October 22, 1872. February 27, 1873.	Good. Good. Good.	
6 M.	51 Irish.	March 18, 1873.	Ran over.		Plaster Paris; April 11, fenestra in consequence of ulcer; box; April 28, plaster Paris.	May 23, 1873.	Good.	Discharged for intoxication.
7 M.	18 Irish	April 19, 1873.	Railroad accident.	Two inches below knee.	Fract. box; June 15, plaster Paris.	June 11, 1873.	Good.	Ulceration from bandage fenestra.
8 M. 9 M.	35 Irish. 23 Swede.	June 9, 1873. July 6, 1873.	Fall. Struck by spur.	Right, near ankle.	Fract. box; July 10, plaster Paris; July 10, fenestra for wound; Sept. 23, side splints.	August 9, 1873. November 16, 1873.	Good. Good.	Fract. occurred at seat two days before admission. Back injured. Paralysis bladder several days. Wound in ankle; skin bone discharging Aug. 4.
10 M. 11 M. 12 M.	21 Swede. 49 English. 27 American.	August 5, 1873. February 14, 1874. October 18, 1875.	Jump. Run over. Struck against stone.	Just above ankle. No shortening. Right, middle.	Fract. box; Aug. 11, plaster Paris.	September 28, 1873. April 3, 1874. January 17, 1875.	Good. Good. Good.	
13 M. 14 M.	5 American. 21 American	December 22, 1875. November 23, 1877.	Fall. Bale cotton fell on him.	Lower third. Left lower and middle thirds	Fract. box; Jan. 31, gutta-percha.	March 1, 1876. December 13, 1877.	Good. Good.	
15 M.	45 Irish.	July 15, 1878.	Mining accident.	Left comminuted.	Fract. box; Nov. 29, side splints.	July 15, 1878.	Died 8 hrs after admission.	Depressed fracture skull; fract. left acetabulum.
1 F. 2 M.	42 American. 28 Canadian.	December 17, 1879. July 12, 1872.	Fall. Thrown from wagon.	Left. Comminuted.	Compound. Fracture box; December 18, dextrine bandage. Fracture box; August 28, plaster Paris; Sept. 1, plaster Paris; 3, side splints.	December 27, 1879. September 17, 1872.	Good. Good.	Occurred thirteen days previous to admission.
1 M. 2 M. 3 M. 4 F. 5 M.	23 Irish. 25 American. 42 American. 59 French. 20 American	July 22, 1870. December 20, 1871. April 13, 1874. April 6, 1877.	Fall. Fall. Fall. Fall. Kicked	Left: lower third. Lower and middle third. Right. "Lower fifth." ext.	Simple. Fracture box. Fracture box. Side splint; April 25, plaster Paris. Fract. splint, and, April 10, ext.	August 20, 1870. July 17, 1871. February 7, 1872. May 25, 1874. May 14, 1877.	Good. Good. Good. Good. Good.	

COMPLICATED INJURIES, RAPIDLY FATAL (INCLUDED IN THE PRECEDING).

Sex.	Age.	Nativity.	Date of Admission.	Cause.	Indication of Fracture.	Treatment.	Date of Discharge.	Result.
1	M.	21	American.	November 2, 1871.	Railroad accident.	Comp. fract. of right femur; commin. fract. of left femur.	—	Died in a few hours.
2	M.	24	American.	January 31, 1872.	Railroad accident.	Comp. fract. of leg, and penetrating wound of thigh down to four lower ribs near vertebra connected with fracture of four lower ribs near vertebra; commin. fract. of left femur; comp. commin. fr. of right tibia and fibula.	—	Died in three hours from admission.
3	M.	13	American.	February 17, 1872.	Railroad accident.	Comp. fract. of leg, and fracture of four lower ribs near vertebra connected with fracture of four lower ribs near vertebra; commin. fract. of left femur; comp. commin. fr. of right tibia and fibula.	—	Died in half an hour.
4	M.	12	American.	February 8, 1874.	Railroad accident.	Comp. commin. fracture of femur; commin. fracture of tibia; fracture of tenth dorsal vertebra; fract. of the eleventh dorsal vertebra; and commin. fracture of clavicle.	—	Died two hours after admission.
5	M.	31	Canadian.	April 9, 1874.	Railroad accident.	Comp. commin. fract. of left femur; comp. commin. fr. of right tibia and fibula.	—	Died one hour after admission.
6	M.	24	Irish.	April 10, 1875.	Fall of heavy timber.	Dislocated, of tenth dorsal vertebra; fract. of the eleventh dorsal vertebra; and commin. fracture of clavicle.	—	Died in nine hours from admission.
7	M.	—	Irish.	September 24, 1875.	Railroad accident.	Comp. commin. fract. of left femur; comp. commin. fr. of right tibia and fibula.	—	Died in half an hour after admission.
8	M.	57	—	April 25, 1876.	Railroad accident.	Comp. commin. fract. of right femur; commin. fract. of left femur; commin. fract. of right radius; fract. of right tibia; fract. of right tibia and fibula.	—	Died in one and a half hours after admission.
9	M.	24	American.	August 29, 1877.	Railroad accident.	Comp. commin. fract. of right femur; commin. fract. of left femur; commin. fract. of right radius; fract. of right tibia; fract. of right tibia and fibula.	—	Died in two hours after admission.
10	M.	13	Scottish.	May 16, 1878.	Fall from third story.	Depressed fract. of skull between frontal and parietal bones; commin. fract. of right radius; fract. of right tibia; fract. of right tibia and fibula.	—	Died on admission.
11	M.	45	Irish.	July 15, 1878.	Mining accident.	Small, transverse, open, extended fract. of skull; fracture of both arms; comminuted fracture of left tibia.	—	Died eight hours after admission.

HUMERUS.

There were seventeen cases, all of simple fracture of which thirteen were in males and four in females. The right humerus was broken in two cases, the left in six, and in nine it is not stated. Of seven—en, one died from interperence, three days after admission, and the average residence of sixteen was forty-four days. As to the location of fracture, four were in the upper third, one middle third, two junction of middle and lower thirds, two lower third, two external condyle, three internal condyle, one both condyles, and two not stated. In treating these cases, angular splints, external or internal, were used in nearly all of those of the lower portion. Plaster of Paris was applied in three cases.

RADIUS AND ULNA.

Seven cases, of which six male and one female. Of these, two were of the right arm and one of the left, four not stated. Of these seven, one was discharged, at his own request, on the seventeenth day, and of the remaining six the average residence was thirty-seven days. As to location, one was in the upper third, one in the middle, one at the junction of middle and lower, two in the lower third, one in which the radius was broken in the lower and the ulna in the upper, and one not stated. Antero-posterior splints were chiefly used.

Radius. Seven cases: five males, two females; three of the right, one of the left, and four not stated. The average residence was forty-three days. Four were of Colles's fracture, two of the lower end, and one just below the tubercle. Anterior and posterior splints were chiefly used.

Ulna. Eight cases: six males, two females; two of the left, six not stated. Of the eight cases, one died immediately after admission from other severe injuries, and of the remaining seven the average residence was forty-one days. Of these fractures, one was of the olecranon, two of the upper third, one of the middle, and four not stated. In the case where the olecranon

was fractured, the degree of separation on admission or discharge is not given.

FEMUR.

There were thirty-seven cases in all, of which ten were of the neck of the bone. Of these ten, there were six males and four females. In only one instance is the side given, and that was the right. Of these cases, one left, one was discharged for misbehavior early in the treatment, and one was discharged on the eighteenth day with "*union firm*," so that in this case, presumably, there was an error in diagnosis. Of the remaining seven the average residence was ninety-one days. The amount of shortening on entrance is not stated in seven cases; one had no shortening, but eversion, and in two there was one inch. At the time of discharge the condition is not stated in five, and of the rest one had no shortening (not the same as on entrance), one had one fourth inch, one one half to three fourths inch, one three fourths inch, and one one inch. The treatment was chiefly by Buck's method, with the addition sometimes of sand bags and long splints.

There were twenty-three fractures of the shaft of the femur, and of these twenty were males and three females. Of these, eight were of the right thigh, eight of the left, one of both, and six not stated. Two of these cases died, one on the second day after admission, and one in a few hours, with a compound fracture of the other femur. Of the remaining twenty-one cases, three were removed by friends, three fell while convalescent, and refractured the thigh, remaining in the hospital respectively one hundred and twenty-eight, one hundred and thirty-six, and one hundred and ninety days, and for the remaining fifteen the average residence was eighty-three days. On admission the amount of shortening is not stated in fifteen cases. Three had two inches, and one each had one and three fourths inches, one and one half inches, one inch, and one half inch. In the case in which both femurs were broken, the left was one half inch shorter. At the time of leaving the hospital the amount of shortening is not stated in nine cases; in three there was one inch, in one three fourths inch, in three one half inch, and in one each, one fourth to one half inch, one third inch, and one eighth inch; in three there is said to have been no shortening. In the case of both femurs, the limbs were of equal length. Buck's apparatus was very generally employed, followed by plaster of Paris. One case, admitted November 28, 1874, was remarkable from the rare complication of a compound dislocation of the internal cuneiform bone, which was forcibly replaced, and the patient made a good recovery.

There were four cases of compound fracture, all of which terminated fatally shortly after admission.

PATELLA.

There were two cases, both male, one stellate and one of the left transverse. The degree of separation is not given. The former was in the hospital ninety-nine days, and the fragments were "found in good position" shortly before leaving, the treatment consisting of a posterior splint, adhesive strips, and a figure-of-eight bandage. The other was in the hospital but twenty-three days, and was treated by a posterior splint and elastic bands.

TIBIA AND FIBULA.

Of these there were seventeen cases of simple fracture, of which fourteen were males and three females,

two of the right, six of the left, and nine not stated. Two died, one shortly after admission, and one from pneumonia following a fractured rib; two left the hospital; and one was discharged at his own request on the thirteenth day. The average residence of the remaining twelve was seventy-seven days. As to location, there were two in the upper third, one at the junction of the middle and upper, four in the middle third, seven in the lower third, and three not stated. In one case the fibula was fractured three inches, and in another one inch, below the tibia. The degree of shortening is given only in five cases on admission; of these, three had one inch, one had three fourths inch and one had one half inch; it is given in only two instances on discharge, one having three eighths inch and one no shortening. The treatment in the majority of cases was by the fracture box, although plaster of Paris was used in a few cases. One case of ununited fracture was admitted, the fracture occurring sixty-eight days previous; he remained in the hospital seventy-eight days, and was treated by the fracture box and the dextrine splint. He was discharged at his own request, with "the fibula united and the tibia quite firm."

There were twelve cases of compound fracture of these bones, all in males; one was of both legs, two of the right, and nine not stated. Six died within a few hours of admission, and one was removed early in the treatment. Of the remaining five the average residence was one hundred and twenty-six days. The fracture box and fenestrated plaster-of-Paris bandages were chiefly employed. There are no statistics as to shortening.

Tibia. There were fifteen cases of simple fracture of this bone, of which fourteen were males and one female. Three were of the right leg, two of the left, and ten not stated. One died in a few hours after admission from a fracture of the skull, and of the remaining fourteen the average residence was seventy-three days. As to location, six were in the lower third, one lower and middle, one middle, one upper third, and six not stated. The fracture box was chiefly used, but in a few cases plaster of Paris or side splints were applied.

There were two cases of compound fracture of this bone, one male and one female, one of the left leg and the other not stated. One occurred thirteen days prior to admission, and after remaining ten days was discharged; the other remained sixty-seven days.

Fibula. There were five cases, four male and one female; one of the right, one of the left, and three not stated. The average residence was thirty-eight days. Three were in the lower third.

DISLOCATIONS.

There have been but eight cases of uncomplicated dislocations admitted to the wards of the hospital during the ten years covered by these tables. Of these, four have been of the thigh, all in males from twenty-six to forty years of age. Two were of the left thigh, and two not stated. Two were upon the dorsum ilii, one into the ischiatic notch, and one into the foramen ovale. All were reduced by manipulation according to Dr. Bigelow's method.

There were two dislocations of the humerus, one in a boy aged fourteen, "forwards and upwards," occurring two days before admission, and one in a man aged forty, upon the dorsum of the scapula, occurring eleven days before admission. Both were easily reduced.

There was one dislocation of the radius and ulna backwards, of long standing, in a man thirty-six years of age, admitted November 14, 1871. Frequent efforts were unsuccessfully made, and in the last of these, the pulleys being in use, a fracture of the bone was produced, which bone is not stated. He, however, left the hospital after a stay of six weeks, with improvement in the motion of the joint.

There was also one dislocation of the outer end of the clavicle in a man aged twenty-seven.

CONCLUSION.

Such are the somewhat meagre results that are on record for these first years of the existence of the hospital. Like all other institutions this has to grow into popular favor, and its second decennial will probably witness a larger number of cases coming under treatment. At all events, this comparatively small number will, I trust, furnish some details of interest to the reader, and may be regarded as a simple contribution to the study of fractures.

PROVIDENCE, April 29, 1880.

RECENT PROGRESS IN PHARMACEUTICAL PREPARATIONS.

BY BENNETT F. DAVENPORT, M. D.

PARAFFIN OINTMENTS AND OLEATES.

ALL cerates and ointments, especially those subject to becoming soon rancid, keep well if made up with some soft paraffin base, such as is now sold under the name of petrolina, or with the paraffin ointment proposed in the printed report of the committee of the American Pharmaceutical Association on the Revision of the United States Pharmacopoeia for 1880.

A subnitrate of bismuth ointment made up with such a base is considered as much better in many cases than the more commonly used zinc ointment.

A series of oleates will doubtless be official in the United States Pharmacopoeia for 1880, the oleate of mercury having already been in use for some years. The oleates of the alkaloids, such as of aconitia two per cent., morphia five per cent., quinia twenty-five per cent., and veratria two per cent., furnish elegant methods of administration.

TAMARINDS.

An extract of tamarinds, which would properly be called "mellago tamarindorum," corresponding to the "pulpa tamarindorum" of the Pharm. Germ., being a clear, brown-red, thick, honey-like mass, is very favorably mentioned by Dr. H. Hager as a preparation for making a refrigerant drink, to be used in fevers, when dissolved in cold water; also as a purgative, if given in doses of three to four spoonfuls.

NEW POULTICE.

A new form of poultice has been introduced by a French chemist as a substitute for linseed and other ordinary poultices. It consists of an extract from Irish moss (*Fucus crispus*) dried between sheets of cotton wool. For use, a piece of suitable size is cut and dipped in boiling water, until quite swollen; then applied to the part, and covered with the accompanying piece of gutta-percha sheeting. It possesses the great advantages of being cleanly, of not drying quickly, of not easily slipping from its place, and of not having any unpleasant odor, as well as of being so quickly and simply prepared. It is offered in packages containing sheets five by eight inches and eight by thirty.

ELASTIC CAUSTIC CRAYON.

Elastic crayons of nitrate of silver can be prepared by dipping small laminaria tents in thick mucilage, and then rolling them in finely-powdered lunar caustic. When dried it makes a crayon which can be introduced into a cavity without fear of breakage. Other caustics can be used in like manner.

SCOPARIN, SPARTEINE, AND SCLEROTIC ACID.

Increased attention has been recently directed, in Germany, to the diuretic action induced by the subcutaneous injection of the active principles scoparin and sparteine, obtained from the broom (*Sarothamnus scoparius*) dissolved in water with the aid of glycerine. A preparation for use as subcutaneous injection has also been made from ergot in the form of sclerotic acid, the ordinary dose being 0.02 to 0.03 grammes. The acid is an amorphous, cinnamon-brown substance, readily soluble in water. Good ergot contains some four to five per cent. of it. It seems to have all the virtue of ergot itself in inducing uterine contractions, and does not lose its strength if only kept dry. It has the advantage over ergotin of not being likely to induce inflammation at the seat of puncture, and over any other preparation of ergot in the smallness of its dose and rapidity of action if used as a hypodermic injection.

ETHYL BROMIDE.

Ethyl bromide, the hydrobromic ether of older chemists, first made by Serullas in 1827, shortly after the discovery of bromide itself, received but little attention as a therapeutic agent until Dr. Nunnally, of Leeds, England, called attention to it as a useful anæsthetic in 1865. Rabuteau, of Paris, again created considerable interest by his experiments with it on the lower animals in 1876; but the credit of bringing it out prominently and, as it now seems, permanently is due to Dr. Lawrence Turnbull, and the hearty coöperation, persevering efforts, and experiments of Dr. R. J. Lewis, both of Philadelphia. As an anæsthetic it has always thus far proved safe when a pure preparation only has been used. In action it is more rapid than even chloroform, and is eliminated by respiration more quickly than either of the common anæsthetics; the senses and muscular coördination being therefore regained very soon after the inhalation ceases. The pulse and respiration are but slightly increased. It causes less irritation of the respiratory passages than ether, and less of the skin on contact than chloroform. The liability to nausea and vomiting is not as much after either of these. The quantity required to produce anæsthesia, as with the more common ether and chloroform, varies with the individual and the modes of administration.

Dr. Levis recommends that it be given by pouring two to three fluid drachms upon some soft, porous material inclosed within a folded napkin large enough to cover the entire face. This held at first closely over the mouth and nose makes a rapid and decided impression, and thus, as with ether, anesthesia is attained with but a very short stage of mental and muscular excitement. The same precautions in administration and against pushing the anesthesia to an unnecessary degree should be observed as with ether. The odor being more agreeable than that of ether, and being also more rapidly removed, it can be used with more comfort in the physician's office or the patient's chamber. As its vapors are not inflammable, there is not the danger of explosion near a light which exists in the case of ether.

CASTOR-OIL.

Castor-oil may be so palatable that a patient will not recognize it, if it is made into an emulsion containing castor-oil $\mathfrak{z}\text{i}$, tinct. cardamom. comp. $\mathfrak{z}\text{iv}$, ol. gaultheriae gtt. iv , pulv. acacie and pulv. sacchari alb. \mathfrak{aa} $\mathfrak{z}\text{ij}$, aq. cinnamomi q. s. ad $\mathfrak{z}\text{iv}$; misce secundum artem. German children are even said to quarrel over the confection of castor-oil made into a paste with either about three parts of coarsely granular sugar or two parts of comp. licorice powder, and flavored with a little powdered cinnamon or grated lemon peel.

KOOSO.

Kooso, one of the most certain of tænicides for tape-worm, is prepared, unimpaired in its strength and in a form which does not excite repugnance, by treating $\mathfrak{z}\text{ss}$. of fresh powdered kooso with $\mathfrak{z}\text{i}$. of hot castor-oil, and afterwards with $\mathfrak{z}\text{ij}$. of boiling water by displacement, expressing and by means of the yolk of an egg combining the two percolates into an emulsion; adding gtt. xl . of ether, and flavoring with some aromatic oil. This emulsion is to be taken at one dose early in the morning, after a previous fast of nearly a day. The worm is usually expelled dead after about six to eight hours.

CINCHONIA AND QUINIA.

Cinchonia can be very acceptably administered in the form of a troche if accompanied by a little carbonate of soda, so as to make the mixture alkaline, and thus prevent its solution and taste in the mouth. Quinine finds a very good solvent in milk, which almost completely disguises its bitterness if taken in the proportion of f. $\mathfrak{z}\text{i}$. to the grain. This mode of administering quinine is of especial use with children. A solution of quinine in glycerine made gr. i. to the f. $\mathfrak{z}\text{i}$. can be given in a cupful of milk without the child knowing it.

IRON ALBUMINATE.

An albuminate of iron has been for some years in use in Germany containing about five per cent. of ferric oxide. It is a perfectly transparent, light brown liquid, nearly tasteless, which will keep well in cool weather for several weeks. It can be obtained from its solutions by precipitation with common salt, and this when dried and powdered is again readily soluble in water.

SUCCUS CARNIS AND DEFIBRINATED BLOOD.

Succus carnis, or meat juice, is extensively used in St. Petersburg by invalids and infants in the place of raw meat, which is simply prepared from fresh, perfectly lean beef by hydraulic pressure, and is consumed on the same day it is made, as it does not keep well

for more than twenty-four hours. It is a clear, red liquid, having an acid reaction. Flavored with a little salt it has a pleasant taste, and under the microscope shows a few blood cells and fat globules. Its specific gravity is 1031 to 1037. It mixes clear with a little hydrochloric acid, but is coagulated by more, or by boiling. It is relished and readily digested even by very young children. It contains in 100 cc., organic matter 6.12 grams, mineral matter 1.04, and water 92.84 grams. The 1.04 grams of organic matter are composed of albumen 3.86 per cent., sugar 0.30, and gelatin, creatin, isatin, etc., 1.96 per cent., while the 1.04 grams of mineral matter contained 0.064 grams of phosphoric acid, principally in the form of acid phosphates of potassium and calcium.

This preparation, as not having been subjected to heat, and thus deprived of its albumen, is superior as a food to all the beef extracts prepared with heat. A somewhat similar food is made by defibrinating and then drying beef blood. This is then dissolved in a mixture of one part each of glycerine and brandy to four parts of water, in the proportion of one drachm of the dried blood to one fluid ounce of the above mixture. This preparation is found to be very palatable and easy of digestion.

SODIUM ETHYLATE.

Sodium ethylate, a caustic alcohol, was first used in 1870. It is a white crystalline material, easily prepared by the action of metallic sodium upon absolute alcohol. This material is recommended by Dr. B. W. Richardson, of London, to be prepared for use by dissolving one part of it in one and one half of absolute alcohol, and dispensed in a bottle furnished with a glass stopper ending in a pointed glass rod, which descends nearly to the bottom of the bottle. This solution, when applied to living tissue, absorbs water, liberates soda, which acts as a caustic, and alcohol, which coagulates the tissues, and thus prevents the decomposition of the dead organic substance which is found. Used, therefore, as a caustic upon vascular growths, it reduces them to a mere dry mass. If a more concentrated solution than the above be used the caustic action is over-severe, and hemorrhage may follow.

PERFUMED CARBOLIC ACID.

Perfumed carbolic acid is prepared from carbolic acid one part, oil of lemon three parts, alcohol of thirty-six degrees one hundred parts, mixed. This mixture, which appears to be quite stable, has only the odor of lemon, is what has been known as "Lebon's perfumed carbolic acid," the formula for which has long been kept secret, but has now been made known in the *Moniteur Scientifique* of Paris. The antiseptic properties are in no way affected by the oil of lemon.

NEW DISINFECTANT.

A new disinfectant has been introduced in Australia composed of one part of rectified oil of turpentine and seven parts of benzine, with five drops of oil of verbenia to each ounce of the mixture. Its purifying and disinfecting properties are due to the power possessed by its ingredients of generating peroxide of hydrogen or ozone. Articles of clothing, furniture, wall-paper, books, and papers may be saturated with it without damage. When it has once been freely applied to any rough or porous surface its action persists for an almost indefinite period. This may be shown readily

at any time by putting a few drops of a solution of iodide of potassium upon the surface which has been disinfected, when the ozone, which is being continually generated, will quickly liberate the iodine from its combination with the potassium, giving rise to a yellow discoloration, or a blue if boiled starch has been added to the iodide of potassium solution.

MENTHOL AND THYMOL.

Menthol, the camphor from the oils of the mints, such as peppermint, and thymol, the camphor from oil of thyme, with their isomeric substances from the other volatile oils, which are homologous with phenol, are becoming largely used as more agreeable antiseptics, in the form of lotions, ointments, soaps, etc., than the more common carbolic acid, the commercial form of phenol. The Chinese having long used their oil of peppermint as a local application in neuralgic affections, and the Japanese also under the name of *po-ho-yo*, an alcoholic solution of from one to ten per cent., scented with a little oil of cloves, has become popular in England for such purposes. A saturated solution of thymol in water, that is, a one tenth of one per cent. solution, is found to be sufficiently strong for the spray during surgical operations. Milk will dissolve thymol up to about ten per cent. Ordinary camphor rubbed up with thymol will liquefy it in all proportion between two and one tenth parts of the thymol. Thymol and chloral hydrate triturated together do not liquefy each other as when ordinary camphor is used, but these three rubbed up together in equal proportions at once liquefy into a powerfully antiseptic solution, which will mix with the soft paraffin ointments in almost any proportion. Its solubility in water, however, is not much greater than that of simple thymol. These camphors, like the ordinary camphor, all dissolve readily in ethers, alcohols, and oils, both fixed and volatile.

FERROUS IODIDE.

All previous processes proposed for preventing the alteration of ferrous iodide being more or less defective, C. Pavesi recommends the use of albumen for this purpose. Having made the ferrous iodide as is usual for the *syr. ferri iodid.* of the United States Pharmacopoeia, then for each part of iodine which has been used three parts of dry soluble egg albumen and five of mannite are added, the whole is heated to 104° F., and filtered through paper after all has dissolved. The filtrate is then evaporated to perfect dryness by gentle heat in a shallow capsule, and is preserved in glass-stopped bottles. Thus prepared, it is in brilliant, pale yellow, odorless scales, very soluble in water, and giving no reaction of free iodine with starch paper.

SUBERIN.

An impalpable cork powder under the name of suberin has come into use for the treatment of chapped nipples and other like purposes. It is dusted on after first washing the nipple, and then covered with a piece of gold-beater's skin, cut star-shaped, in the centre of which punctures are made with a needle. When the child is suckled the powder is washed off with water, and the skin replaced, the child drawing the milk through that without giving pain. After each nursing the powder is dusted on again, and the gold-beater's skin placed over it. It is also being used for the chafing in children instead of lycopodium, being preferred on account of containing tannin, and also costing much less.

ODORLESS IODOFORM.

The odor of iodoform is very much disguised by the presence of the volatile oils, such as peppermint and cloves, and also by balsam of Peru. Five to eight drops of the oil of fennel to the gram of iodoform is considered, however, to be the most effectual.

PYROGALLIC ACID.

Ointment of pyrogallic acid is being used instead of that of chrysophanic acid in many cases with good results. Psoriasis is the disease for which it has been chiefly tried, and the most convenient strength has been found to be that of ten per cent. Most of those who have tried it—for instance, Professor Hebra—prefer the remedy to chrysophanic acid. They find that, though its action is slower, it has the advantage over the latter in exciting scarcely any inflammation in the part to which it is applied, and in staining the skin but slightly, the brown color produced by it quickly disappearing. Hebra has never yet seen any poisonous symptoms follow its application to the skin, although in his cases it could always be detected in the urine. A case has, however, been lately reported by Dr. A. Neisser, where a patient died with the symptoms of pyrogallac acid poisoning in the skin clinic at Breslau. One half of the body of a robust man having been covered with a chrysophanic acid, and the other half with a ten per cent. pyrogallac acid ointment, he was attacked with vomiting, and died in collapse on the fourth day. The urine was dark brown, and had a thick sediment, which consisted of a very abundant blackish-brown substance, partly amorphous, and partly in the form of casts, but containing no blood cells. As the spectrum showed the characteristic bands of hemoglobin, and similar *debris* to that in the urine was found in the blood itself and in the renal tubules, there could be no doubt that it consisted of disintegrated red blood corpuscles. Dr. Neisser explains its poisonous action by its activity for oxygen in the presence of alkalies, and the consequent destruction of the red blood corpuscles, which are the carriers of oxygen. He considers that its use had best be restricted to the head and face, while chrysophanic acid may be used upon the surfaces covered by the clothing.

NITRO-GLYCERINE.

Nitro-glycerine can be prepared for use in a solution either of alcohol or of ether, a one per cent. solution in alcohol being that generally preferred. It being also soluble in melted cocoa butter, this has been employed for making it into pills, but in this form it does not act so quickly as in alcoholic solution. A better plan than this is to add an equal quantity of chocolate paste to this pill mass, and then make it up into lozenges of any desired size, which it would not be disagreeable to chew up in the mouth, and thus gain rapid absorption.

Nitro-glycerine bids fair to prove an anti-neuralgic of the greatest value, especially in cases of angina pectoris and such other affections as nitrite of amyl has hitherto been much used in, taken at intervals of two to four hours, in doses of about two drops of the one per cent. solution, and increased until full physiological action is obtained. The relaxed condition of the blood-vessels induced lasts usually about half an hour. Doses of the above strength and frequency have been continued through several consecutive days with safety and success in warding off threatening attacks of angina pectoris in cases in London hospitals.

Reports of Societies.

PROCEEDINGS OF THE OBSTETRICAL SOCIETY OF BOSTON.

C. W. SWAN, M. D., SECRETARY.

A CASE OF LABOR, WITH CONSTRICTION OF THE INTERNAL OS.

OCTOBER 11, 1879. DR. L. R. STONE, of Newton, reported the case. The patient, a primipara, fell in labor in the early part of the evening. At one A. M., when Dr. Stone saw her, the external os was dilated to the size of half a dollar, and was somewhat rigid; the pains were slow and weak; at four o'clock there was some yielding of the os, and at six o'clock complete dilatation, though quite a long cervix remained, not with the circular orifice of the os uteri as generally found. The head was presenting, the occiput being in the left anterior position. The forceps were applied *through the cervix*; strong traction was made without effect; and the instruments, slipping, were readjusted, and finally slipped off entirely. On making a further examination the finger felt the firmly constricted inner os, hard, rigid, and unyielding, traceable in its entire circumference about the child's neck, but the shoulders could not be reached. The patient had been etherized, and was kept so with the object of producing relaxation. At 1.30 P. M. the forceps were again put on and the patient, with a good deal of labor, was finally delivered. The child was dead. For ten days afterwards the pulse ranged from 120 to 130, and the temperature averaged between 101.5° F. and 102° F., never exceeding 103° F. There was no doubt that the difficulty was occasioned by the rigidity of the inner os, which at first was so firm that the finger could not get beyond it. No constriction was detected through the abdominal wall. The pelvis was large and roomy, and the head was partially engaged in the superior strait when the forceps were applied.

DR. HOSMER remarked that in the class of cases to which that reported by Dr. Stone belongs, the constriction could be reached by the finger through the vagina, the whole head being in the cervix and the constriction about the neck. In another class the constriction is about the trunk of the child. In the original idea of hour-glass contraction its true nature was misunderstood. Playfair's theory is that the cavities are those respectively of the *body* and of the *neck* of the uterus. Bandl has demonstrated that the cervix has a remarkable capacity for elongation. Dr. Elliott, of New York, has alluded to some cases in which the constriction of the internal os had taken place about the neck of the child. In these cases, as in that of Dr. Stone, the stricture had been dilated. Those, on the other hand, which Dr. Hosmer had himself reported appeared to belong to a different class, in which the forceps, theoretically, are likely to do harm, and practically are useless, and in which Cæsarean section rather than craniotomy seems to be the indication.

DR. RICHARDSON said that Dr. Stone's case may be classed with those of Bandl, who accounts for the condition by the os getting caught down, the cervix stretching, and the internal os going up over the head and claspings the neck of the child.

DR. HOSMER said that it was worthy of note that in Dr. Stone's case there was some relaxation under ether, whereas in his own, seen in 1876, there was not the slightest yielding, the firm band holding like iron.

It was a question, he said, whether there were two distinct classes of cases, or whether one was transformed into the other; whether there ever was a constriction which should be made to pass from the neck to the trunk by the spontaneous passage of the shoulders. It was not probable, — not easy to see.

DR. RICHARDSON asked if it might not be possible that these two kinds or classes arose respectively from cases in which the whole os was caught down, and those in which the anterior lip only was so held.

DR. HOSMER remarked that the gravity was in proportion to the amount of elongation of the cervix. When a firm falciform constriction takes place about the trunk there is a condition of things which is extremely grave.

DR. STONE, in answer to a question, stated that the forceps were applied through the os, although the cervix had not disappeared, the finger detecting both its outer and inner surfaces.

DR. NICHOLS, of Cambridge, observed that Dewees speaks of a condition of contraction of the internal os as constituting a very serious condition, in which delivery neither by forceps nor by turning is practicable. His cases had been relieved by bleeding, a safer proceeding than that suggested by Dr. Hosmer.

A CASE OF ABDOMINAL TUMOR, WITH ASCITES.

DR. ADAMS, of Waltham, gave the following account: The patient was an unmarried woman, fifty-four years of age, not over five feet two inches in height, who first noticed in the right inguinal region, sixteen years ago, a movable tumor of the size of a goose's egg. Dr. Adams first saw her ten years ago. At that time the abdomen was already unusually enlarged, fifty-three and a half inches in girth, fluctuating everywhere, presenting no distinct localized tumor, dull throughout in front, and resonant in the lumbar regions. With these indications the case was supposed to be an ovarian cyst. The patient continued to do her work about the house, until, about a week ago, she could no longer breathe with comfort, and her stomach refused to contain anything. The girth at the umbilicus had reached seventy-one inches, and the distance from the ensiform cartilage to the navel was twenty-one. As she stood the tumor reached half-way below her knees; as she sat it reached within four inches of the ground. Dr. Adams tapped with a very small trocar, and removed twenty-two quarts of clear fluid, which became gelatinous on standing. On withdrawing the trocar the fluid continued to flow for upwards of thirty-six hours. Then it was determined that the effusion was ascitic. The abdomen now showed a large, freely movable, hard, and nodular tumor, extending from a hand's-breadth above the umbilicus down into the pelvic cavity. There was still entire dullness in the region of this tumor, and resonance in both lumbar regions, although the level of the ascitic fluid remained above these points, the abdomen not having been emptied. Menstruation had been regular until about five years ago, when, after a fall, the flow entirely ceased for two years; during the last three years there has been a constant oozing, never profuse.

THE FORCEPS IN RELATION TO RUPTURES OF THE PERINÆUM.

DR. C. E. STEPMAN said that it had been stated that an appreciable increase in the percentage of cases of rupture of the perinæum had been observed, while there had been a corresponding decrease in the cases of ves-

ico-vaginal fistula appearing in our hospitals, since the more frequent use of the forceps in labor during the last five or ten years. He had asked Dr. Chadwick to make some inquiries at the last meeting of the American Gynecological Society about this relation of rupture of the perinaeum to the wider use of forceps, and he had received the following memoranda:—

"My experience is that nine-tenths of complete ruptures of the perinaeum are caused by the use of the forceps.

WILLIAM GOODSELL."

"I should not make the proportion quite so large, for many ruptures occur in delivery of head and arms in head-last labors; but I should say that lacerations in the second and third degrees have been greatly increased in frequency by the more frequent use of the forceps which has characterized obstetric practice during the last decade.

T. G. THOMAS."

Dr. Stedman said that rupture of the perinaeum depended on the dilatability of that structure, and that he knew of no sure preventive except incision. He had tried all the expedients recommended without avail in certain cases, and had heard confessions of the same ill-fortune from better men than himself. He had followed the practice, for the last two years, of removing the instrument before the head was born (unless speedy delivery was imperative); but it made no difference in the result if the perinaeum was not lax. He did not remember to have had a rupture into the sphincter. Fortunately, most of these lesions took care of themselves. Many ruptures were made by the after-coming shoulders, when the head had passed safely.

Dr. LYMAN said that he was astonished at the statements of Goodell and Thomas. Of the many cases seen at the City Hospital almost all had been delivered without the forceps. He could not remember a single one of these cases in which the rupture had been traced to the use of forceps. An occasional bad rupture has no doubt been so caused, but not the vast majority. It should be noted that until recent years the laboring class had not been examined for the lesions so frequently as now.

Dr. FORSTER said that he had seen several cases where no forceps had been used; very few where they had been employed.

Dr. ABBOT said that the worst case coming under his observation had occurred without the intervention of forceps, the laceration extending into the rectum an inch above the sphincter, the child having been born before the physician reached the house. He had met with two pretty extensive lacerations under the use of the forceps, but these might fairly be called accidental. In Charlestown he had seen in consultation a young woman who at the time of his visit had been in labor forty-eight hours. The head was above the pubes, the face anterior, the os very rigid and not more than two inches across, the uterus being firmly contracted upon the body of the child. The pains had nearly ceased. At the urgent solicitation of the attending physician ether was administered, causing a relaxation of the os, and the forceps were applied; but the delivery for a time resisted the alternate efforts of the two attendants, until finally the head was suddenly extracted, tearing the perinaeum to the anus. Three superficial stitches were put in, and complete union resulted. In another case, in which he had been consulted by Dr. Borland, a similar laceration occurred in a somewhat different way. The forehead was at the pubes, and the patient, fully etherized, lay in a dorsal position across the bed. The forceps

had thus far failed to effect extraction. It was then proposed to remit the ether and swing the patient about, to give her an opportunity of bracing her feet against the foot-board. While she was in this position a pain came on, and she suddenly straightened herself out, bringing the child at once "into the world" by her own efforts, the forceps meanwhile being merely steadied by the attendant, who was standing behind the foot-board. In this case the laceration went through the sphincter. Sutures were employed as in the other case, and the parts healed well. In another case, which Dr. Abbot had visited with a member of this society, the patient had been in hard labor all night. The face was to the pubes. Forceps were applied, and Dr. Abbot supported the perinaeum while extraction was made by the attending physician. The perinaeum became so distended as to appear as thin as tissue paper, when suddenly a zigzag streak, at least four inches long, tore down on one side, and the delivery was accomplished. In the subsequently contracted condition of the parts the laceration proved to be insignificant, requiring no special treatment.

In the ordinary use of the forceps Dr. Abbot said that he felt that the physician had complete control. When the head was low it was his custom to unlock the forceps without taking them off, so that the tension on the external parts might be relieved, the instrument being in readiness for renewed application should farther extraction be required. He had employed forceps in ten and a half per cent. of his cases for the last twenty years, and his only regret was that he had not used them as freely before.

A NEW METHOD OF PERFORMING DECAPITATION.

Dr. RICHARDSON described in detail a new method of performing decapitation. He favored the combined use of Ramsbotham's knife and Braun's decollator: the latter being used for the purpose of breaking the cervical column, and the former for cutting through the soft parts. He claimed that decapitation was indicated in cases in which there was no hope of saving the life of the child, and the condition of the mother demanded operative interference, and in which delivery neither by version nor forceps could be easily effected, and the neck of the child could be reached.

AN OBSCURE LOCAL TROUBLE IN THE REGION OF THE STERNUM IN A CHILD.

Dr. HODGDON reported the case. The patient, who was first seen by Dr. Hodgdon in the last week in July, after a course of treatment by an irregular practitioner, was a child two and a half years of age, naturally healthy and of healthy parents, with the following history: It had been taken sick in the evening, vomiting, with high fever and great sensitiveness to touch. It continued in this condition for a week, when a small swelling was observed over the sternum. At the end of another week the then attendant informed the parents that an abscess had formed there and had opened internally. When Dr. Hodgdon first saw the patient there was a purplish prominence one and a half inches in diameter, half an inch in elevation, elastic, without fluctuation, situated over the lower part of the body of the sternum, at the site of the sternal foramen. When the patient was etherized it was found that the tumor could be pressed back through the sternum, but would return when the pressure was taken off. The patient was seen by Dr. Wyman, of Cambridge, in con-

sultation, and the question of mediastinal abscess was discussed, the usual site of which was, however, different from that of the tumor under consideration. Two days later Dr. Hodgdon explored the swelling with a subcutaneous syringe, which gave exit to serum and gas, the latter with a fizzing sound. Continuous compression was kept up over the tumor for two weeks without effecting an appreciable change; but the child, which was at first much emaciated and without appetite, regained strength and ran about the house, a graduated compress being kept over the tumor. At the end of two weeks more it was found that the tumor had disappeared, that the breast was smooth, and that the parts of the sternum which at the site and the time of the disease had been movable on each other were now firm. A hacking cough, which was present when the child was first seen, and which lasted for some weeks, had disappeared. There were no physical signs of pulmonary disease. Dr. Hodgdon was inclined to ascribe the tumor to the theory of a portion of lung pressing up through the sternal foramen, or through an opening resulting from inflammation.

Dr. ABBOT queried whether this case were not one of emphysema, caused by a giving way of the bronchi at the bifurcation and escape of air into the cellular tissue, as in a case of labor under his care, where the patient, making great exertion, felt a sudden pain in the chest, which was followed by a blowing up of the tissues from the eyes down to the breasts. He inquired if the patient had had a cough before the occurrence of the singular condition reported, which might possibly have had some connection with it as a cause, and was answered in the affirmative by Dr. Hodgdon, who said the child had been troubled for some time by a short hacking cough.

Recent Literature.

Paracentesis of the Pericardium. A Consideration of the Surgical Treatment of Pericardial Effusions.
By JOHN B. ROBERTS, A. M., M. D., Lecturer on Anatomy in the Philadelphia School of Anatomy, etc. With Illustrations. Philadelphia: J. B. Lippincott & Co. London. 1880.

This carefully written monograph has deservedly met with favorable notice, and is justly appreciated by the medical press and by the profession as being the only complete work in our language on paracentesis of the pericardium, a subject about which Dr. Roberts has previously written one or more articles, and to which he has devoted special study for several years. Although the attention of physicians has been long directed to the desirability of paracentesis in cases of considerable pericardial effusion, instances of the performance of this operation are of rare occurrence, and the text-books, as a general rule, as the author remarks, contain little information regarding it. Exception must be made, however, in favor of Reynolds's *System of Medicine*,¹ which, in a very complete article on pericarditis, gives a satisfactory account of the methods and results of paracentesis, obtained in part from the monograph under consideration. Professor Trousseau's work on *Clinical Medicine* also contains a valuable chapter on the same subject.

Dr. Roberts first notices the fact that there is often

an accumulation of serum, even to the extent of three ounces, within the pericardium, the result of post-mortem transudation. He then refers to the rare occurrence of pericardial distention in acute pericarditis, on account of the rapid absorption which usually takes place. Still, cases have been recorded in which the enormously distended pericardium has contained a gallon of fluid. The diagnosis of small effusions is attended with much difficulty, but the author mentions that Dr. Rotch was able, by percussion of the fifth right intercostal space, to detect the presence of seventy to eighty cubic centimetres of fluid introduced into the sac experimentally. The gravitation of the effusion to the lower part of the pericardial sac, which was also demonstrated by Dr. Rotch, leads the author to regard the triangular or pyramidal area of flatness, referred to by many writers as characteristic of pericardial effusion, as of doubtful or infrequent occurrence, and of little value in diagnosis.

The best points for tapping are thought by Dr. Roberts to be the fossa between the ensiform and the costal cartilages on the left side, and the fifth left interspace near the junction of the sixth rib with its cartilage, with a preference for the latter point, where there is less risk of puncturing the diaphragm. The danger of wounding the heart, which is a practical one, as is shown by several recorded cases, is perhaps underestimated by the author, who considers tapping the ventricle of less serious moment than puncturing the auricle, which is more likely to occur if too high a point is chosen. The necessity for further clinical investigation before adopting Dr. Rotch's suggestion to tap in the fifth right interspace, four to five centimetres from the edge of the sternum, is mentioned; but should this prove to be an available point, the dangers above alluded to would be to a great extent, or entirely, obviated.

Sixty cases of paracentesis are tabulated, of which thirty-six died, most of them with complications which were necessarily fatal, and twenty-four recovered. The greatest age was sixty-eight years, and the patient was tapped twice; the second time the puncture was made on the right of the sternum.

It is noticeable that within a few days of the appearance of Dr. Roberts's volume Dr. C. Hindenlang reported in the *Deutsches Archiv für klinische Medizin*, October 23, 1879, two cases of paracentesis pericardii, one occurring in Professor Räumler's clinic at Freiburg, and the other in Professor Kussmaul's at Strassburg. In connection with these two cases Dr. Hindenlang reviews the literature of the subject, and records fifty cases of paracentesis, with a favorable result in about one third. Puncture with a fine trocar connected with an aspirator is recommended at a point three or four centimetres to the left of the sternum, in the fourth, fifth, or sixth interspace, according to the amount of effusion.

Professor Kussmaul's case was interesting from the fact of the coexistence of right-sided pleurisy with extensive pericardial effusion. The needle was inserted in the fifth right intercostal space, outside of the mamillary line, and twenty cubic centimetres of clear serum flowed. When the needle was pushed deeper, however, a brownish-red muddy fluid escaped to the amount of seven hundred and fifty cubic centimetres. Four days later the operation was repeated with similar result, five hundred and fifty cubic centimetres of clear pleuritic fluid being withdrawn, followed on

¹ American Edition, vol. ii.

deeper puncture by two hundred and fifty cubic centimetres of red serum, which was thought to be pericardial. The patient recovered.

Dr. Roberts's interesting monograph, together with Dr. Hindenlang's recent clinical observations, and Dr. Rotch's original investigations with regard to the diagnosis of pericardial effusion published in the *JOURNAL* in October, 1878, have thrown new light upon one of the most important and difficult subjects in clinical medicine. The cases of rheumatic pericarditis, however, which require tapping appear to be very rare; perhaps more so now than formerly, since, with better methods of treatment, we have in many cases comparative control over the joint affection, upon the intensity of which, and the exhaustion arising therefrom, the pericardial inflammation is to a considerable extent dependent.

Health and Health Resorts. By JOHN WILSON, M. D. late Medical Inspector of Camps and Hospitals in the United States Army. Philadelphia: Porter and Coates.

Health and Health Resorts is a sort of mild guide-book for searchers after health on the continent of Europe, interspersed with moral reflections, a little pathology and physiology, and with some remarks on the *modus operandi* of curative agents generally and individually. The reason the author gives for not touching upon the sanitary resorts of the United States, namely, that they have been already described in a number of able works, might have equally restrained him from writing about those of Europe, particularly as he expressly disclaims any pretension to better judgment or more extended observation than many writers who have preceded him. What he says, however, if not always new, is sometimes true, and will bear repetition, as when he suggests that very sick people would often do better to rely upon the resources of their own land than to risk the sufferings and dangers which expatriation so frequently entails. In the chapter on Expatriation a sensible and glowing tribute is paid to the varied advantages of health resorts which the citizen of this country enjoys at home. These advantages deserve and will receive greater appreciation.

Photographic Illustrations of Skin Diseases. By GEORGE HENRY FOX, A. M., M. D. Parts VII., VIII., IX., X., XI., XII. New York: E. B. Treat, No. 805 Broadway.

The recent publication of the above parts, with a promptness unusual in a series of its character, brings this work to a close. The subjects chosen for illustration are: lupus vulgaris, lupus erythematosus, epithelioma superficiale, epithelioma rodens, epithelioma of the lip, trichophytosis capitis, trichophytosis corporis, lichen planus, lichen ruber; kerion, lepra maculosa, molluscum, erythema multiforme; phtheiriasis capitis, phtheiriasis corporis, scabies, porrigo e pediculosis; herpes facialis, hydroa bullosum, erythema circinatum, erythema exfoliativum, purpura simplex; cornua cutanea, alopecia areata, morphea, scleroderma, sarcoma pigmentosum. The plates have the same general merit as those in the earlier parts of the atlas already described. Some of them are excellent, others are poor, because the subjects are beyond the reach of photography. Some things are to be felt, not seen.

An attempt to represent such an affection as scleroderma, for instance, by this process fails through want of judgment, not skill. In the matter of titles, too, it is to be regretted that such conditions as hydroa, kerion, and porrigo have been perpetuated in this way as individual affections. The descriptive text is by no means the least important part of the work. It contains many new and interesting views, for the author does not hesitate to hold and express independent opinions about skin diseases. Dr. Fox is to be congratulated on the completion of a work which is in all respects a most valuable contribution to dermatology.

In conclusion, he announces a companion work entitled *Photographic Illustrations of Cutaneous Syphilis*.

The Therapeutics of Gynecology and Obstetrics. Edited by WM. B. ATKINSON, A. M., M. D. Philadelphia: D. G. Brinton. 1880. Pp. 365.

The object of the editor seems to be to present, under the head of each disease, the various methods of treatment which prominent members of the profession, at one time or another, have advised as the best course to be pursued. It is a volume of recipe and directions, and it is hard to imagine a more needless or impractical addition to a medical library. In many cases the bewildered practitioner, called suddenly to a case, would consult this volume, and find under the appropriate heading the most varied and contradictory advice. In many cases, the remedies suggested would appear in the light of to-day to be worse than useless. Convulsions, for example, occur after delivery. The first method quoted advises that the patient be fed carefully on milk diet for the first three or four days. Robust women, who have eaten well up to confinement, require an aperient within forty-eight or even twenty-four hours after confinement. Ergot should be used for the first week or two, if the uterus does not involute as it should. Just how this form of treatment is to relieve the convulsions we are at a loss to understand. If this advice should therefore puzzle the practitioner, he can turn to another authority, who advises him to bleed, or to another, who says that bleeding is of no use, or even hurtful. The author has evidently devoted a great deal of time to the preparation of a book which strikes us as possessing more of a historical than a practical value.

Atlas of Histology. By E. KLEIN, M. D., and E. NOBLE SMITH, M. R. C. S. Part X. Philadelphia: J. B. Lippincott & Co. London: Smith, Elder & Co. 1879.

We have been rather remiss in noticing this last number, which is the less excusable as we have little to say about it. It is of the same excellence as its predecessors, but the subjects discussed do not call for much comment. It treats of the intestine, the pancreas, the liver, and the larynx, trachea, bronchus, and lung. The description of the epithelium of the larynx is very thorough. In the other sections we find mention of the work of numbers of observers.

— Dr. Moubre, of Paris, claims to have made beneficial use of petroleum in chronic bronchitis and phthisis.

Medical and Surgical Journal.

THURSDAY, MAY 27, 1880.

A Journal of Medicine, Surgery, and Allied Sciences, published weekly by HOUGHTON, MIFFLIN AND COMPANY, Boston. Price, 15 cents a number; \$5.00 a year, including postage.

All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.

Remittances by mail should be sent by money-order, draft, or registered letter to HOUGHTON, MIFFLIN AND COMPANY, BOSTON, MASS.

A SPECIAL INSTRUCTOR IN HYGIENE IN THE PUBLIC SCHOOLS OF BOSTON.

CERTAIN members of the School Committee of the Board of Public Instruction of the city of Boston have for some years been impressed with the growing necessity for a direct supervision of the sanitary surroundings and arrangements of the school buildings, for a more especial medical control over the children frequenting the public schools, and for the instruction of the teachers, and of those expecting to become teachers, in matters pertaining to their own health and that of those over whom they have or are destined to have authority. It has been apparent, as the growing importance of these subjects has forced itself upon the attention of these members, that it was quite out of the question to expect the proper fulfillment of such functions from the other officers of the board, whose time is already fully occupied, and whose training has not been of the special character required by these duties.

In 1876, at the earnest and active instigation of Dr. J. G. Blake, who in common with Professor H. P. Bowditch, the other medical member of the school committee, has taken a deep interest in this subject, it was proposed to establish a new office, namely, that of Medical Inspector of Public Schools. Several gentlemen, among others, Drs. Folsom, Lincoln, and Nichols, as well as Hon. James M. Barnard and Dr. Blake himself, appeared before the committee appointed for a hearing of the subject, advocating very strongly the establishment of such an office; and the step would doubtless have been taken at that time had not the city solicitor informed the committee that in his opinion it did not possess the requisite legal powers.

The time which has since elapsed has only served to impress more forcibly those having the subject most at heart with its grave importance, and with the feeling that the city of Boston cannot discharge the duty which she undertakes toward her children unless their bodily welfare as well as their mental training receives due consideration. Good ventilation, a favorable light, suitable desks and seats, protection from contagious and miasmatic diseases, are not a whit less important to the child at school than methods of teaching or text-books; even those who differ as to the best means of obtaining these are agreed as to their vital value. Moreover, although it is felt that Boston has already postponed this step too long, she may still be a pioneer in the field of school hygiene, and her past history in regard to public education makes it incumbent upon her to press forward, to lead instead of waiting to follow.

When it is remembered that there are at the public schools of Boston between fifty-five and sixty thousand children, and more than twelve hundred teachers, the responsibilities of the city and of the officers connected with the department of public instruction are brought forcibly before the mind.

The school committee has now resolved, out of deference to legal technicalities, to appoint a special instructor in hygiene. This position, as at present regarded, is provisional for a year and a half, but it is hoped the result will justify its being made permanent. We are informed that the school committee are prepared to consider the names of candidates for the appointment. The duties of the instructor in hygiene will be the following:—

(1.) The special instructor in hygiene shall be a regularly educated physician, who shall, unless specially excused by the board, devote his whole time to the duties of his office.

(2.) He shall, under the direction of the committee on the Normal School, deliver annually a course of not less than ten lectures on hygiene to the pupils of that school. He shall also, if desired to do so by the board, deliver lectures upon the same subject to the pupils of the English High and Girls' High Schools and to the teachers in the service of the city.

(3.) He shall visit the grammar and primary schools as often as his other duties will permit, paying particular attention to the sanitary condition of the premises and to the physical condition of the pupils.

(4.) He shall endeavor to impress upon the minds of teachers and pupils the importance of observing hygienic laws, and he shall have authority to exclude from the schools any pupil whose health may be endangered by attendance at the prescribed exercises.

(5.) He shall examine the localities selected and the plans proposed for the erection of school-houses, and shall report his opinion of the same in writing to the committee on school-houses, for their guidance in deciding upon such location or plans.

(6.) During the erection of any school-house he shall examine the work as it progresses, in order to ascertain whether the sanitary arrangements called for in the plans and specifications are actually supplied in the construction. If it shall appear that such is not the case, he shall immediately report the fact to the committee on school-houses, which committee is hereby authorized to act at once upon such report with full powers.

(7.) Whenever, in the opinion of the special instructor of hygiene, the sanitary condition of any school is such as to require immediate action, he shall report the facts in the case to the committee in charge, and annually, in the month of May, he shall report in writing to the board upon all matters connected with the hygienic management and condition of the schools.

In all cases of doubt, teachers and truant officers shall consult the instructor in hygiene, whose decision shall be final.

The salary of the special instructor in hygiene has been fixed at three thousand dollars.

SUITS FOR FEES.

A CASE recently tried in the superior civil court presents some points of interest to the profession. Dr. Edward de la Granga sued Samuel P. Bennett for professional services. The bill as itemized was as follows: 153 visits at \$5, \$765; two night visits at \$20, \$40; one extra visit, \$10; one operation and sundries, making, with charge for interest, a total of \$959.10. The bill was disputed by the defendant on the ground of excessive charge, and he also filed a claim in partial set-off. The case was referred to an auditor, who reported that the principal conflict of evidence was upon the question of price per visit, that these visits extended over more than three years, and that the plaintiff had for a long time previous to the first item of the bill been attending physician to the defendant and his family. Up to the date of the first item full settlement had been made, and the visits had been charged at the rate of three dollars, except in extraordinary cases; but the plaintiff claims that about this time he notified the defendant, who acquiesced, that his charges in future would be at the rate of five dollars. This the defendant denied, and he supposed the rate was the same as he had been charged before. Plaintiff's books and vouchers put in evidence show that for several months after the alleged change from three to five dollars per visit the visits charged to the defendant were at the rate of three dollars, which the plaintiff claims was a mistake on his part, which he corrected further on in charges made that year, where the visits were carried out at the rate of five dollars per visit. The auditor fails to find sufficient evidence of a special agreement that the plaintiff was, with the defendant's consent, to charge him five dollars per visit, and hence is compelled to resort to expert testimony in relation to the custom of the profession in such cases. A long and searching examination and cross-examination of Drs. Damon, Chase, Clark, Hall, Hastings, Holt, Stacey, Lamson, Fleming, Harris, and Cilley, all practicing physicians in the city of Boston, convinced the auditor that the usual and fair charge for such visits is and should be three dollars per visit. The auditor allowed for 153 visits at \$3, two night visits at \$10, one extra visit at \$5, and one operation at \$10, in all \$494. He allowed in set-off \$171.14, awarding to the defendant \$322.86, with interest from time of writ.

The plaintiff refused to accept the award of the auditor, and the case came up for jury trial. As before the auditor, the conflict of testimony was chiefly as to what was a fair charge for the visits. Drs. Warner, Chase, Treadwell, and Clark testified that the usual and fair charge was five dollars per visit, and Drs. Ayer, Lamson, Stedman, Fleming, Newell, Harris, and Cilley that it was three dollars. Dr. Lamson testified that it was oftener two than three, which gave counsel for plaintiff the opportunity to quote the third clause of the provision in regard to fees from the code of the Boston Medical Association. The attempt was made to introduce the fee table of this association to show what the charges should be.

On objection by counsel for plaintiff the judge (Rockwell) ruled that it could not be introduced, neither could questions based upon it be put. The fee table was simply an agreement of a private nature between physicians, and no one was under any legal obligation to abide by it, neither was a patient obliged to pay fees prescribed by it. The only question for the experts was this: "What is a fair compensation per visit for a physician of the experience and standing of this physician for such services as described?" If a member of a particular association violates the provisions of the fee table of that association, he is accountable to the society alone. It is nothing with which the law has to do.

The jury awarded the plaintiff \$290.86. As the plaintiff had refused an offer of more than this amount in court, the costs of trial fall upon him. There is no way to ascertain exactly on what basis the jury made the award, but comparing it with the items in the auditor's report, it is probable that they awarded on the basis of three dollars for the regular visits in attendance.

This case shows that none of the profession can go into court and claim their charges as just on account of the provisions of the local fee table. They must take what experts testify that such services are worth, or, rather, such part of such sum as a jury will allow. The case would apparently be different, however, by the statement of the auditor, if it could be shown that there had been due notice given of the charge per visit; and so it behooves every physician who expects to collect a higher fee than three dollars (and there are many cases where a charge of five dollars would be only reasonable) to make a special agreement beforehand if he is likely to be obliged to appeal to the courts for his payment.

It seems also as if there were quite a difference between what is a *fair* charge and what is a *usual* charge. There is no doubt that, taking the profession as a whole throughout the city, there are more fees under three dollars than of that sum itself. It may be disguised under the name of discount or deduction for the circumstances of the patient, or of extra visits not charged for, or in some other way, but Dr. Lamson was right in saying that the fee was often two dollars, especially for mechanics and others receiving the same rate of pay.

 MEDICAL NOTES.

— The Massachusetts Medical Society will meet on Tuesday, June 8, 1880. At ten o'clock, A. M., there will be operations, surgical visit, and exhibition of patients at the Massachusetts General Hospital, in Blossom Street; at the Boston City Hospital, on Harrison Avenue; at the Carney Hospital, in Old Harbor Street, South Boston; and at the Lying-In Hospital, 21 McLean Street. At twelve o'clock will be the meeting in Horticultural (upper) Hall, 100 Tremont Street, to hear papers read as follows: (1.) Pneumonia, by Charles D. Hunking, M. D., of Haverhill.

(2.) Pyæmia of Doubtful Origin, apparently Spontaneous, by Charles H. Cook, M. D., of Natick. (3.) Antiseptic Treatment of Empyema, by Arthur T. Cabot, M. D., of Boston. Adjournment at two o'clock. At three o'clock, the reading of papers will be resumed as follows: (4.) Edema of the Lungs, with Illustrative Cases, by Henry F. Borden, M. D., of Brockton. (5.) Relation of Bacteria to Disease, by William F. Whitney, M. D., of Boston. (6.) Diphtheria and the Resulting Paralysis, by Andrew F. Reed, M. D., of Holyoke. (7.) Ambulatory Treatment of Hip Disease, by Charles P. Putnam, M. D., of Boston. During the afternoon the Warren Museum, at the Medical College, North Grove Street, the Warren Museum of Natural History, 92 Chestnut Street, the Children's Hospital, 1429 Washington Street, and the Museum of the Natural History Society, Berkeley Street, will be open to the society.

The programme for Wednesday, June 9, 1880, is as follows: The ninety-ninth annual meeting of the society will be held in Horticultural Hall, Boston, at nine o'clock, A. M. Order of proceedings: (I.) Records, and Names of New and of Deceased Fellows. (II.) Reports of Committees. (III.) Medical Papers and Communications: (8.) The Importance of Early Recognition of Ear Disease, by J. Orne Green, M. D., of Boston. (9.) Cape Cod as a Health Resort, and some Remarks pertaining to Sanitary Science, by Peter Pineo, M. D., of Hyannis. (10.) Litholapaxy, by Henry J. Bigelow, M. D., of Boston. (IV.) Introduction of Delegates. Intermission of fifteen minutes. At twelve o'clock, precisely, the annual discourse will be delivered by Thomas H. Gage, M. D., of Worcester.

In the Lower Horticultural Hall there will be an exhibition of surgical instruments and various pharmaceutical preparations.

The annual dinner will be served in the Music Hall, at one o'clock, P. M. N. B. — Fellows will enter the Music Hall by the Tremont Street entrance only, being called in order of seniority in Horticultural (upper) Hall, whence the procession will start. J. Collins Warren, M. D., is the anniversary chairman.

The annual meeting of the councilors will be held at the Medical Library, No. 19 Boylston Place, Boston, on Tuesday, June 8, 1880, at seven P. M.

The censors for Suffolk District, officiating also for the State Society, will meet for the examination of candidates for fellowship, on Thursday, June 3d.

—The eighty-ninth annual convention of the Connecticut Medical Society takes place in New Haven, May 26th and 27th.

—The Massachusetts Dental Society will hold its fifteenth semi-annual meeting at 167 Tremont Street, Boston, on Thursday and Friday, June 3d and 4th. On Thursday, at eleven o'clock, papers will be read as follows: (1.) The Dentist as a Plunderer, Dr. J. T. Codman. (2.) Mechanical Philosophy as an Element of Dental Education, Dr. George F. Grant. (3.) Care of the Temporary Teeth, Dr. Edward Page. Friday, at nine o'clock, Dr. Bonwill will demonstrate his method of anticipation of decay by actual

operation. He will exhibit his surgical engine, in use in the University of Pennsylvania and Jefferson Medical College, for operations on the bones and mucous surfaces. Physicians and surgeons are cordially invited to be present and examine the instrument.

—The *Michigan Medical News* says with regard to summer complaint in children: "The season of disaster among infants is even now upon us, and the bulk of the physician's practice during the next few weeks will be in caring for the bowel complaints of children. Doubtless the vast majority of these complaints are directly traceable to errors in diet. The physiological fact is unknown to the vast majority of mothers, and is forgotten or disregarded by very many physicians, that the infant before it has its teeth does not secrete saliva in sufficient quantity for the digestion of starch food, and the consequence is the general prevalence at this season of infantile diarrhoea. Cow's milk, next to that of the mother the most natural food for the child, very rapidly sours during this weather, unless greater precautions are taken than is generally possible, and it thus becomes a fruitful cause of trouble. What is wanted is a food which shall obviate the objection to both farinaceous or starchy preparations and milk. It remained for Liebig to prepare a formula for such a food, and many physicians can testify to its success." The very great improvement of late years in the preparation of children's foods is certainly noticeable, although such essentials to successful treatment are not always within the reach of the class who need them most.

—The *Chicago Medical Gazette* divides medical colleges into four classes: " (1.) Colleges which, from their circumstances and surroundings, have the power to introduce any desired reform, and do it. (2.) Colleges which, from their circumstances and surroundings, have the power to introduce any desired reform, but, with an eye to dividends, do not do it. (3.) Colleges which, from their circumstances and surroundings, have not the power to introduce reforms to the extent which they would desire, but do their best. (4.) Colleges which, from their circumstances and surroundings, have neither the power nor the inclination to introduce any desired reforms, and do not try.

"Foremost among the first class is Harvard Medical College. The preliminary examination has been so modified and extended as to require the degree of Bachelor of Science, or its equivalent, including the translation of easy Latin prose. The experiment is also made of adding a fourth year to the course, upon the completion of which will be conferred the degree of Doctor of Medicine, *cum laude*. Although at present the student may graduate after the usual course of three years, it is believed that the college will soon exact from every candidate for examination the entire four years. The fourth year's studies include clinical medicine, clinical and operative surgery, ophthalmology and otology, dermatology and syphilis, mental and nervous diseases, laryngology, hygiene and legal medicine, obstetrics, clinical and operative, diseases of women and diseases of children. Harvard is ahead!"

—The same journal says: "Dr. Stansbury Sutton, of Pittsburgh, Pa., who was the successful competitor last January in the *concours* for the lectureship of gynaecology in the spring faculty of Rush Medical College, has just completed his course of thirty-nine lectures. Two hundred and thirty-six students were in attendance. Dr. Sutton in his lectures mainly followed the teachings of Emmet, and is thought to have given one of the most satisfactory courses ever delivered in Chicago on gynaecology. He expects to return for another course next year, but has not arranged as yet to change his residence.

Relative to the *concours*, the *British Medical Journal* remarks that the *concours* seems to be adopted only in cities fully organized, like Paris, or very young, like Chicago, and declares that in London students are kept well in their place by compulsory attendance upon all the lectures, and only the lectures specified, in order that their certificates may be signed; that the lecturer is sure of his class, whether he be audible or inaudible, or good, or bad, or indifferent; and that the London schools furnish a large amount of inefficient lecturing. The *British Medical Journal* thinks these schools might profit by a breath of reform which the system of *concours* would blow in upon them. It is notorious that the *concours* in Paris is sometimes corrupt. It is probable that in London or in any other city it would be exceedingly liable to become so. In Chicago, the fairness of the *concours* thus far will be universally admitted. It has, moreover, been the means of securing excellent lecturers. It has certain objections, however. Manifestly, any man who could be secured to the college by the *concours* could be secured without the *concours*. The college would therefore have a much larger number of eligible men from whom to select the lecturer, since many would be reluctant to enter such a contest and take the chances of being advertised afterwards as having failed, — a sort of advertisement not damaging to a recent graduate, but exceedingly unpleasant to a gentleman whose experience and attainments qualify him to lecture acceptably to a class of two hundred and thirty-six students in a medical college. Rush College is at least to be congratulated on the excellent advertisement which this *concours* has furnished in the favorable announcements and comments which have appeared very generally in the medical journals, both at home and abroad."

—This extract from a valedictory recently delivered at the Buffalo Homoeopathic College is, to say the least, significant: "The elision of the term [homoeopathy] could be of no detriment to the denomination; in our judgment, it would be benefited in every way, — a great gain and no loss. In the minds of many it is the great barrier to progressive medicine, to professional tolerance and a high social status, to liberty of thought and action, to freedom of sentiment, speech, and practice. Its name and extravagant notions have kept in abeyance the careful examination of the most scientific method of treating disease, for the great mass of professional men have been tutored from their early pupillage to look upon it opprobriously. It has proved

the great obstacle to admission to army, navy, and health boards. Its exclusive dogma limits the research of its pupils, curbs the ambition of the practitioner, checks the progress of liberality and reform, and brands its votaries in the estimation of the majority as charlatans. The student should not be fettered by any dogma, pathy, or ism. The broad fields of science and art should be his realm, and he should be permitted to bask in the glowing light of reason and experience."

NEW YORK.

—At the meeting of the American Medical Association the following papers will be read, in addition to those already announced in the JOURNAL: —

Section on Practice of Medicine, Materia Medica, and Physiology. Progressive Muscular Atrophy and Pseudo-Hypertrophy, by Drs. J. D. Kerlin and Charles K. Mills, of Philadelphia; Microscopical Sections from Cases of Diseases of the Brain and Spinal Cord, by Drs. Charles K. Mills and Karl Seiler, of Philadelphia; On the Use of Sulphur and its Compounds in the Treatment of Diseases of the Skin, by Dr. L. Duncan Bulkley, of New York; Diphtheritic Poison, by Dr. J. T. Everett, of Sterling, Ill.; Artificial Inflammation as a Remedial Agent in Diseases of the Lungs, by Dr. W. T. Galloway, of Yazoo City, Miss. (to be read by Dr. J. Solis Cohen, of Philadelphia); The Electric Treatment of Exophthalmic Goitre, by Dr. A. D. Rockwell, of New York; A Case of Recovery from Occlusion of one or more of the Cerebral Sinuses, by Dr. M. O'Hara, of Philadelphia; Empyema and its Treatment by Excision of the Ribs, by Dr. ———, of Pennsylvania.

Section on Surgery and Anatomy. Laparotomy and Colotomy, with the Formation of Artificial Anus for Obstruction of the Intestines, by Dr. W. A. Byrd, of Quincy, Ill.; A New Inhaler, by Dr. D. M. Barr, of Philadelphia; Thoracentesis, by Dr. C. A. Leah, of New York; Cystotomy in Cystitis of the Male, by Dr. Robert F. Weir, of New York; Hip-Joint Disease, First Stage, with Microscopical Sections, by Dr. De Forest Willard, of Philadelphia; Repair Processes of Osseous Tissues, illustrated by Micro-Photographs, by Dr. H. O. Marey, of Cambridge, Mass.; The Theory of Inflammation, founded upon Original Investigations, and illustrated by Sections of Bone, by Dr. C. Heitzmann, of New York; A Method of treating Spinal Disease, by Dr. E. H. Grover, of Harrisburg, Pa.; Some Points in the Treatment of Hamorrhoids, by Dr. W. R. Blackwood, of Pennsylvania; On the Foramen of Monro in Man and the Domestic Cat, by Dr. Bart G. Wilder, of New York; The Treatment of Fracture of the Long Bones involving Joints, by Dr. James S. Green, of Elizabeth, New Jersey.

Section of Medical Jurisprudence, Chemistry, Psychology, State Medicine, and Public Hygiene. The Climate and Diseases of the Mississippi Valley, by Dr. Joseph Jones, of Louisiana; The Relations of the Medical and Legal Professions to Criminal Abortion, by Dr. E. H. Parker, of Poughkeepsie, N. Y.; Un-

sanitary Engineering, by Dr. A. N. Bell, of Brooklyn, N. Y.; The National Board of Health, by Dr. J. S. Billings, U. S. A., of Washington, D. C.; The Disposal of Sewage, by Dr. Charles F. Folsom, of Boston; The Temperature of Sewing Rooms, by Dr. R. C. Kedzie; The Moral Treatment of the Insane, by Dr. Charles W. Page.

Section on Ophthalmology, Otology, and Laryngology. Anatomical Peculiarities of the Cerebral Artery, by Dr. F. B. Loring, of Washington, D. C.; On Tumors of the Lachrymal Gland, their Pathology and Operative Treatment, with Demonstrations of Specimens, by Dr. H. Knapp, of New York; Demonstration of Models to illustrate the Refraction of Light by Asymmetrical Surfaces: to be followed by Remarks on the Determination and Correction of Astigmatism, by Dr. H. Knapp, of New York; On Perichondritis Auriculae, with Presentation of a Case, by Dr. H. Knapp, of New York; The Etiology of Ozena, by Dr. R. C. Brandeis, of New York.

The title of the paper by Prof. T. Gaillard Thomas before the section of Obstetrics and Diseases of Women and Children should read Ablation of the Uterus in Non-Malignant Tumors, instead of simply Ablation of the Uterus, as previously announced. At the request of Prof. A. Jacobi, there will be a special sub-section for the reading of papers and discussions on diseases of children. It is now definitely decided that the entertainment on the evening of Wednesday, June 24, will consist of the play of Othello at Booth's Theatre, with Mr. Booth in the part of Iago and Mr. F. W. Robinson in the title rôle. The committee of arrangements are having abstracts of Cushing's Manual printed for general distribution among the members of the association, so that there will be no excuse for any one infringing parliamentary rules during the session. The committee are also having maps of the city prepared, with the location of the different houses where receptions are to be given on Thursday evening marked upon them, for the convenience of those unfamiliar with the streets.

During the general session of the association papers on the advances and discoveries of the past year in the branches of science included in their respective sections are to be presented by Dr. J. S. Lynch, of Baltimore, chairman of the section on Practice of Medicine, etc., Dr. Albert H. Smith, of Philadelphia, chairman of the section on Obstetrics, etc., Dr. W. T. Briggs, of Nashville, Tenn., chairman of the section on Surgery and Anatomy, Dr. James F. Hibbard, of Richmond, Ind., chairman of the section on Medical Jurisprudence, etc., and Dr. Bolling H. Pope, of New Orleans, chairman of the section on Ophthalmology, etc. The following committees will also report: on prize essays, Dr. Austin Flint, New York, chairman; on necrology, Dr. J. M. Toner, Washington, D. C., chairman; on catalogue of National Library, Dr. H. C. Wood, Philadelphia, chairman; on ozone, Dr. N. S. Davis, Chicago, chairman; on metric system, Dr. T. Parvin, Indianapolis, chairman; on state medical societies, Dr. S. D. Gross, Philadelphia, chairman.

ST. LOUIS.

— At the regular meeting of the St. Louis Medical-Chirurgical Society, April 10th, Dr. Hudson Ford read a paper on the treatment of cystitis dependent upon the enlarged prostate of old age. The principal points were that when there was retention he recommended puncturing the bladder through the rectum, and maintaining this opening till the urethra was again pervious, and he stated that the arrangement of the muscular layers of the bladder was such that they formed a sort of sphincter vesicae, which was under the control of the will. In the way of medication, he recommended washing out the bladder with a two-ounce solution of nitrate of silver, five grains to one ounce, to be followed by the injection of four or five ounces of pure water. A few days later, if the cystitis continues, repeat this treatment, increasing the strength of the solution by five grains. This course is to be repeated at intervals of a few days, increasing the strength of the solution by five grains, till twenty grains to the ounce is reached, if the cystitis is not cured before that time. This plan was suggested to him by Dr. T. G. Richardson's method of treating cystitis occurring in young men. The ordinary measures were advised combined with these.

At the same meeting Dr. Charles Todd asked for suggestions in regard to a case which had applied to him for relief from the annoyance resulting from a noise which was produced whenever the sterno-cleido-mastoids of one side was called into action. The doctor described it as being audible at least a foot from the patient, and resembling the sound made by bubbles passing through a viscid fluid. It was thought it might be due to a bursa under the muscle, or to movements of the inter-articular cartilage in the articulation of the inferior maxillary. No satisfactory conclusion was reached.

The society appointed Dr. John T. Hodgen, Dr. W. A. Hardaway, Dr. Charles Michel, and Dr. William Glasgow delegates to the American Medical Association.

MEDICO-LEGAL.

— In one of his clinical lectures (*Gaz. des Hôp.*, January 27th), Professor Depaul observes that at the present day we readily admit that the death of the *fœtus in utero* need in no wise compromise the health of the mother; but some thirty years ago a frightful picture was still drawn of the effects of such an accident, and the idea has not yet quite disappeared from the mind of the public. Indeed, such fear does the death of the *fœtus* sometimes cause in a family that it is necessary to take precautions in announcing it. This comes from confounding maceration with putrefaction, although they entirely differ from each other. Putrefaction occurs when the contact of air gives rise to changes in the tissues contained in the uterus, and may develop very serious symptoms, as, for example, when the membranes are not expelled after an abortion, and become putrefied. But the infant being inclosed in a double sac, the air cannot gain access to it; and, instead of putrefaction, maceration results. Sometimes the dermis of the infant is raised into

ampullæ, whence exudes a sero-sanguinolent liquid that gives to the amniotic fluid the color of wine-lees, which is rendered still darker by the meconium that is expelled on the relaxation of the sphincters just before death. It would seem that some of this liquid is absorbed, as it is diminished in quantity, while its color becomes as dark as coffee-grounds. On analysis, blood in an altered condition and the elements of the meconium are discovered. An infant may remain in this state within the uterus for some months, especially in twin pregnancies, when one of the infants compressing the other causes it to become flattened and atrophied, so as exactly to resemble a little gingerbread figure. These details may prove of importance in legal medicine, for when a woman has been accused of infanticide it may be shown that the infant has been dead for some time from disease of the placenta or from other causes.

— New Hampshire. In an action against a town for personal injuries from a defective highway, the rule as to the degree of care required to be exercised by the plaintiff in the employment of a physician and surgeon, and in procuring and submitting to proper medical treatment, is not changed by the fact that the plaintiff was himself a physician and surgeon.

Disceplany.

HYPNOTIC COLOR-BLINDNESS.¹

MR. EDITOR.—Professor Heidenhain and Dr. Grützner report that with certain people slight pressure or stroking the brow and temporal region of one side produced on the other side a more or less complete cataleptic condition in the upper extremity first, and then the lower, the latter not always. The muscles of the face were not always affected, nor was aphasia always caused. In these individuals the eye on the cataleptic side *lost its color sense*. For other phenomena the reader is referred to the original article.

Dr. Cohn, of Breslau, has followed up the examination of the same persons: In Professor Heidenhain's brother, a perfectly healthy young man of twenty-two, not color-blind, normal visual power when his myopia of 7 D. was corrected, and no ocular defect, the following phenomena were observed: Stroking his right brow and temple three times with his right hand produced a cataleptic-like condition of the muscles of the *left* arm and leg, slight facial paralysis, and reduction of the visual power of the left eye to scarcely a $\frac{1}{2}$, this with no loss of consciousness. His visual power was restored to normal at once, however, when a glass of —11 D. was placed before the eye instead of his own —7 D. There was therefore spasm of accommodation in this left eye equal to —4 D. In meantime his right eye kept its myopia 7 D., and vision normal with this glass as before. The near point for Buckard's spots No. 45 approached from seventy to twenty mm. Therefore, with this left eye = 50 — 11 = 39 D.; that is, equal to a lens of 2.5 cm. focus. These tests were repeatedly made, and always resulted in —11 D., being the best glass for distance during the hypnosis. The pupil retained its size and mobility. Light perception remained equal nity. The perimetric visual field for white perfectly normal. The visual power for *red* and

green, on Stillings's long card, sunk, notwithstanding correction by concave 11 D., to $\frac{2}{3}$; for yellow and blue to $\frac{1}{2}$. *The color sense in this left eye was wholly gone.* This was carefully proved by nearly all the present methods of testing: Holmgren's, Donders's, Daas's, Stillings's, Snellen's, Cohn's; colored shadows, successive contrast, the spectrum, etc.

In the hypnotic condition he had with the stereoscope no sensation of perspective, no phenomena of glance or contention of two colors presented, all of which he did have normally when not hypnotic. His brother, the professor, afterwards discovered that dropping into this eye a solution of atropine during the hypnosis caused it to become red-green blind instead of totally color-blind.

Dr. Cohn reports being able to render the eye alone hypnotic, without affecting the rest of the body, by simply warning the other eye with the hand, or letting the person examined do it. This done with Mr. Heidenhain, the colors at first appeared correct, then in their contrast color, then gray (total color-blindness). Removing the finger, the colors appear again in contrast color, and finally normally. This effect can also be produced on the eye warmed by the finger; the experiment cannot be so readily carried out, as the eye cannot of course be covered by the hand.

In some cases it was sufficient to bring a lighted cigar to within twenty-five cm. of the outer angle of the eye to cause the spasm of accommodation to commence, which increased as the cigar was brought nearer up to ten cm., when it suddenly ceased.

At certain distances, monocular diplopia and pleiopia appeared during the hypnosis.

This condition of the eye during the hypnosis resembles perfectly the case of congenital monocular total color-blindness recently reported by Professor Becker and translated in the JOURNAL.

A person who was congenitally totally color-blind distinguished the colors when his eye was rendered hypnotic. Since these observations, Dr. Cohn has followed up the experiments with other color-blind people, and he reports in the *Deutsch. med. Wochenschrift*, No. 16, 1880, the cases of three notoriously color-blind, in whom the defect disappeared on thus warming one eye. These observations are creating a good deal of discussion among physiologists. Some notice of them for the laity may be found in a recent number of the *Nation*. In the only case in which I have at present been able to make the experiment it failed. I should add that aside from the authority from which they come these extraordinary results are well attested.

B. JOY JEFFRIES.

COLOR-BLINDNESS.

MR. EDITOR.—In the report of the Proceedings of the Suffolk District Medical Society, April 10, 1880, published in the last number of the JOURNAL, I am made to say, in reference to color-blindness, that I "did not think the matter could be put so strongly in regard to railroads as it had been lately."

What I intended to say, and, as I believe, did say, was that I thought the need of proper examination for color-blindness among railroad employees could not be too strongly insisted on. Respectfully,

O. F. WADSWORTH.

¹ Breslauer ärztliche Zeitschrift, February 28 and March 27, 1880.

Deaths reported, 2411; 922 under five years of age: principal "zymotic" diseases (small-pox, measles, diphtheria and croup, diarrhoeal diseases, whooping-cough, erysipelas, and fevers) 463, consumption 359, lung diseases 341, diphtheria and croup 130, diarrhoeal diseases 70, measles 56, scarlet fever 50, typhoid fever 39, malarial fevers 39, whooping-cough 30, erysipelas 22, cerebro-spinal meningitis 20, small-pox seven. From *measles* five, New York 18, Cincinnati 13, Brooklyn nine, New Orleans five, Chicago four, Philadelphia three, Pittsburgh two, St. Louis and Springfield one. From *malarial fevers*, New York and New Orleans 13, Brooklyn eight, St. Louis, Baltimore, Boston, Buffalo, and Charleston one. From *whooping-cough*, Philadelphia and New Orleans five, Baltimore four, New York and Brooklyn three, Boston, Cincinnati, and Charleston two, Chicago, St. Louis, Pittsburgh, and Providence one. From *erysipelas*, New York six, Brooklyn three, Baltimore and Boston two, Philadelphia, St. Louis, Pittsburgh, Milwaukee, Providence, New Haven, Lowell, Newburyport, and Fitchburg one. From *cerebro-spinal meningitis*, New York six, Philadelphia four, Chicago and Fall River two, St. Louis, Cincinnati, Buffalo, Pittsburgh, New Haven, and Taunton one. From *small-pox*, Philadelphia three, New York, Chicago, Lowell, and Fall River one.

Ninety-two cases of measles, 42 of diphtheria, 14 of scarlet fever, three of whooping-cough, and two of typhoid fever were reported in Brooklyn; small-pox two, in Chicago; diphtheria 30, scarlet fever nine, small-pox one, in Boston; diphtheria nine, scarlet fever eight, in Milwaukee; diphtheria 18, scarlet fever nine, erysipelas three, typhoid fever three, cerebro-spinal meningitis one, in Providence; diphtheria eight, scarlet fever one, in Cambridge; scarlet fever 12, diphtheria six, in New Bedford.

About the usual number of total deaths; deaths under five

somewhat diminished. The principal "zymotic" diseases considerably increased.

In 36 cities and towns of Massachusetts, with an estimated population of 1,011,560 (population of the State about 1,690,000), the total death-rate for the week was 20.21 against 19.81 and 20.50 for the previous two weeks.

For the week ending April 24th, in — German cities and towns, with an estimated population of 7,687,113, the death-rate was 27.4 against 22.9 and 28.1 for the two previous weeks. Deaths reported, 5660; 2019 under five: pulmonary consumption 637, acute diseases of the respiratory organs 511, diphtheria and croup 147, measles and *röteln* 65, typhoid fever 59, scarlet fever 56, whooping-cough 50, purpural fever 18, typhus fever (Königsberg two, Danzig five, Thorn three, Posen one, Benthien two, Brannschweig two) 15, small-pox (Benthien) one. The death-rates ranged from 16.6 in Mainz to 42.7 in Munich; Königsberg 31.6; Breslau 33.2; Dresden 24.7; Berlin 27.5; Leipzig 26.9; Hamburg 25.5; Hanover 22.1; Bremen 23.8; Cologne 23.1; Frankfurt 17.9. For the same week, Vienna 34.2; Paris 30.8, with a large mortality from small-pox.

For the week ending May 1st, in the 20 English cities, with an estimated population of 7,439,468, the death-rate was 21. Deaths reported, 3015: acute diseases of the respiratory organs 260, 80 below the average, whooping-cough 133, measles 93, scarlet fever 77, diarrhoea 43, fever 30, diphtheria 21, small-pox (all in London) 18. The death-rates ranged from 14 in Brighton and Wolverhampton to 36 in Plymouth again: London 19.8; Bristol 18.7; Birmingham 20; Liverpool 28; Manchester 26. In Edinburgh 22, Glasgow 22, Dublin 28.

The meteorological record for the week in Boston was as follows: —

Date.	Barom-eter.	Thermom-eter.			Relative Humidity.			Direction of Wind.			Velocity of Wind.			State of Weather. ¹			Rainfall.

DR. ISAAC FAIRCHILD.

At a meeting of the New Bedford Society for Medical Improvement, held May 15th, the following preamble and resolutions were unanimously adopted:—

Whereas, Our much-respected and valued associate, Dr. Isaac Fairchild, of Fairhaven, has been removed from us by death; and *whereas*, in our sense of deprivation, we believe it appropriate to express some sentiment of the respect and honor due his memory; therefore,

Resolved, That we feel deeply the loss of our friend, whose honor, integrity, sagacity, and earnestness of purpose induced the high regard in which he was held by this society, and endeared him to us.

Resolved, That the example set by Dr. Fairchild in his professional relations, and in his intercourse with us as a society, is of the highest value, and will be constantly remembered with the regard due the memory of an unassuming, kind-hearted, earnest worker.

Resolved, That this society extends its warmest sympathies to the family of our late member, and would express its hope that their sense of bereavement may be lightened by the knowledge of the universal esteem and respect in which he was held.

Resolved, That the community in which he lived is called upon to mourn the loss of a faithful and skillful physician, and of a man who in his public relations was a model of unswerving integrity and zeal for the public welfare.

Resolved, That in respect to the memory of our deceased colleague this society attend his funeral in a body.

Resolved, That a copy of these resolutions be entered upon the records of this society, a copy sent to the bereaved family, and a copy published in the local papers and in the Boston Medical and Surgical Journal.

W. H. TAYLOR, Secretary.

NEW BEDFORD, MASS., May 16, 1880.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U. S. ARMY, FROM MAY 15, 1880, TO MAY 21, 1880.

SERGEONS J. B. BROWN, J. H. BILL, C. H. ALDEN, and J. S. BELLINGS to represent the medical department of the army at annual meeting of American Medical Association, New York city, June 1, 1880. S. O. 107, A. G. O., May 14, 1880.

VOLLEN, E. P., major and surgeon. When relieved, to report in person to commanding general, Department of the East, for assignment to duty. S. O. 107, A. G. O., May 14, 1880.

BYRNE, C. C., major and surgeon. Relieved from duty in Department of Dakota, and to report in person to commanding general, Division of Pacific and Department of California, for assignment to duty in Department of California. S. O. 107, C. S., A. G. O.

HAPPESETT, J. C. G., major and surgeon. Relieved from duty in Department of the East, and to report to commanding general, Department of Texas, for assignment to duty. S. O. 107, C. S., A. G. O.

DE HANNE, J. V., captain and assistant surgeon. Relieved from duty in Department of Texas, and to report by letter to surgeon-general. S. O. 107, C. S., A. G. O.

McELDERBY, H., captain and assistant surgeon. Upon withdrawal of troops from camp on White River, Colorado, to ac-

company them to railroad, and then repair to Fort D. A. Russell, Wyoming Territory, and report for temporary duty at that post. S. O. 42, Department of the Platte, May 12, 1880.

LATDENHALE, J. V., captain and assistant surgeon. Granted leave of absence for four months, with permission to go beyond sea. S. O. 111, A. G. O., May 19, 1880.

MATTHEWS, W., captain and assistant surgeon. Relieved from duty in Department of California, to proceed to New York city, and report arrival to surgeon-general. S. O. 107, C. S., A. G. O.

BYRNE, C. B., captain and assistant surgeon. To report in person, May 30, 1880, to commanding general, Department of the South, for assignment to duty. S. O. 107, C. S., A. G. O.

MASSACHUSETTS MEDICO-LEGAL SOCIETY.—The third annual meeting of this society will be held at one o'clock on the 8th of June, at the hall of the Boston Medical Library Association, No. 19 Boylston Place, Boston. After the disposal of the regular business (probably at half past two o'clock) the following papers will be read: (1.) Report of the executive committee, by the corresponding secretary, Medical Examiner Abbot. (2.) On Points of Interest in the Case of Jennie P. Clark, by Medical Examiner Pinkham. (3.) On Criminal Abortion, by Medical Examiner Breck. (4.) Medico-Legal Relations of Alcoholism: Its Psychological Aspects, by Medical Examiner Russell. Its Legal Aspects, by Associate Member H. W. Chaplin, Esq. Its Pathological Aspects, by Associate Member G. K. Sabine, M. D. The associate members of this society and delegates from other medico-legal societies are earnestly invited to be present and participate in the discussions of the above papers. Members of the Massachusetts Medical Society are cordially invited to attend this meeting.

ROBERT AMORY,

Recording Secretary and Treasurer.

STEFFOLK DISTRICT MEDICAL SOCIETY.—A regular meeting will be held at the hall, No. 19 Boylston Place, on Saturday evening, May 29th, at seven and a half o'clock. The following papers will be read: Dr. A. N. Blodgett, Hallux Valgus, with a Report of two Successful Cases. Disputant, Dr. C. P. Putnam. Dr. E. H. Bradford, Two Cases of Infantile Paralysis. Disputant, Dr. J. J. Putnam.

All members of the Massachusetts Medical Society are cordially invited to be present, and to take part in the proceedings. Supper at nine o'clock. H. C. HAVEN, M. D., Secretary.

MIDDLESEX EAST DISTRICT MEDICAL SOCIETY.—At the annual meeting of the society, held in Woburn, Wednesday, May 12th, the following officers were elected for the ensuing year: President, Dr. D. W. Wight. Vice-President, Dr. A. H. Cowdrey. Secretary, Dr. George E. Putney. Treasurer, Dr. J. O. Dow. Councillors, Drs. F. Winsor, W. S. Brown, and J. O. Dow. Censors, Drs. Charles Jordan, W. F. Stevens, E. W. Graves, S. W. Kelley, and C. E. Chase. Commissioner of Trials, Dr. F. F. Brown. Nominating Councillor, Dr. Winsor. Reporter, Dr. Putney.

GYNÆCOLOGICAL SOCIETY OF BOSTON.—The next regular meeting of the society will be held on the second Thursday of June, at the Medical Library rooms, at 10.30 o'clock, A. M. Continuation of the discussions last announced. The profession are invited. HENRY M. FIELD, M. D., Secretary.

Lectures.

CLINICAL LECTURES ON ORTHOPEDIC SURGERY.¹

DELIVERED AT BELLEVUE HOSPITAL, NEW YORK.

BY LEWIS A. SAYRE, M. D.,

Professor of Orthopedic Surgery and Clinical Surgery in Bellevue Hospital Medical College.

V. SPINA BIFIDA TREATED WITH PLASTER-OF-PARIS DRESSING: PSOAS ABSCESS IN CONNECTION WITH POTT'S DISEASE.

GENTLEMEN,—The first case which I have to show you to-day is one which has been sent to me from the interior of Indiana, by a very distinguished medical gentleman of the West, for the purpose of having a diagnosis made. It has been pronounced by various physicians and surgeons to be sacro-iliac disease, congenital dislocation of the hip-joints, hip-joint disease, Pott's disease, and lateral curvature of the spine; and now it is asked that I should give my opinion as to what the trouble really is. The patient is a little girl, five years of age, and the history that the mother gives is that a large tumor in the lumbar region, situated directly over the vertebrae, was noticed at birth, and has remained ever since. She did not make any attempts to walk until she was thirteen or fourteen months old, and these were very awkward ones, as she did not seem to be able to control the muscles with any degree of certainty. She has been under the care of seven medical attendants, scarcely any two of whom have agreed in their opinion as to the nature of the case, as the long list of diagnoses which I have just repeated to you shows.

This seems to me most extraordinary, for the case is certainly a very simple one, and I can hardly imagine how an intelligent observer could mistake it for anything else than what it really is. When we come to make an examination here, we find a tumor of considerable size in the lumbar region, occupying the median line, and extending to an equal distance on both sides of the spinal column. On palpation over the latter, moreover, we find that there is a firm osseous wall on either side, and a soft space in the centre, the least pressure over which gives the child a good deal of pain. This soft space, however, is quite small in extent, the spinous processes of the vertebrae being felt, as usual, both above and below it. But one conclusion can therefore be arrived at, and that is that the case is undoubtedly one of well-marked *spina bifida*. A further and minute physical examination of the child fails to detect any other difficulty whatever, and, consequently, I have thought it well to bring the case before you, that it might teach you an important lesson in diagnosis, and serve as a useful warning, so that none of you, when practicing, perhaps, in remote portions of the country, will ever put your patient to the inconvenience and expense of a long journey to some great medical centre for any such trouble as this child is suffering from.

This is a perfectly clear case. There is simply a congenital deficiency in the formation of the spinous processes of the lumbar vertebrae, due to the same arrest of development, as it is called, which results in cleft palate and meningoceles of the cranium. Here, to use a rough illustration, there has been a failure in the formation of the roof of the spinal column; a

bifurcation has remained from fetal life, and, accordingly, at birth there was found a fluctuating tumor in this position. Such tumors always contain subarachnoid fluid, and frequently large nerves, if not the spinal cord itself. When they are present, all that we can do is to wait for nature gradually to form a bony covering over the exposed parts, just as the fontanelles in infants are closed by degrees by an advancing process of ossification. In the mean while it is usually desirable to protect the tumor by some artificial shield, and to endeavor to assist ossification by such internal remedies as seem to be indicated. The space between the bony walls here, which, as mentioned above, is very tender on palpation, is about an inch in circumference. The child apparently enjoys good health, but sometimes it is seized with an acute pain, which causes it to scream out very suddenly. By Seguin's surface thermometer we discover that the temperature of the tumor on the back is three or four degrees higher than that of any other portion of the body.

If any of you have the opportunity of looking at Parker's edition of Cooper's First Lines in Surgery, published, I think, in 1848, you will find in it the report of an interesting case of spina bifida, upon which I operated many years ago at Dr. Parker's clinic at the College of Physicians and Surgeons. At the time the operation was performed the child was seven or eight years old, if I remember rightly, and there was a large pendulous tumor which was attached to the back in the lumbar region of the spinal column, and which had evidently been a spina bifida at the time of birth. I was strongly advised not to attempt to remove the mass, as it was thought that on account of the irritation of the nerves, which no doubt passed into it, tetanus or other severe derangement of the nervous system would in all probability result; but I was of the opinion that if I were to put a ligature around the pedicle so tightly as to cause complete strangulation, and thus actually kill the nerves, no such consequences would ensue.

Accordingly, I passed through its centre a needle armed with a stout double thread, and carrying one strand around one half of it, and the other around the other half, I tied them so tightly that I felt confident that the desired strangulation of the tumor would be accomplished. Great interest was expressed as to the effect which the procedure would have upon the child's nervous system, but, as I had anticipated, there was not a single unfavorable symptom following it. In the tumor, when removed, a bundle of large nerve-trunks was found, thus proving conclusively that it had originally been a spina bifida. About seven years ago this same patient came to me when I was lecturing at Charity Hospital, on Blackwell's Island, with an infant of her own, whose back she wished me to examine, as in the mean while she had grown up to womanhood, married, and had a child.

In this connection I will also mention another interesting case of this kind of arrest of development, which came under my notice some years ago. I attended a woman in confinement in the lower part of the city, and when the child was born I was surprised to find that there was an enormous soft tumor on the back of the neck, almost as large as its head. I expected that the infant would die almost immediately, and was anticipating a very interesting post-mortem; but, contrary to my expectations, it continued to live and fairly thrive. Under the circumstances, therefore, I gave the

¹ Reported for the JOURNAL.

mother large quantities of lime for the purpose of promoting ossification, and when the proper time had arrived I proposed to operate in the same way as in the case which I have just related. Unfortunately, however, when nine years of age, the child died of cholera. I made an autopsy in this case, and presented the interesting specimen thus obtained to Dr. Watts, at that time professor of anatomy in the College of Physicians and Surgeons. It exhibited the same presence of nerves as was found in the other instance, and I hoped to be able to present it to you to-day, but in the short time at command for searching for it in the museum of the college it could not be found.

But to return to the case now before us. You will remember that one of the diagnoses made here was the so-called "double congenital dislocation," which is not properly a dislocation at all, but a malformation of the pelvis, due to an arrest of development, which consists in a non-fusion of the three bones entering into the composition of the acetabulum, and which I prefer, therefore, to call *congenital displacement*. If this condition were present, however, instead of a single tumor, occupying the central portion of the back, we should detect a prominence on each side, over the trochanters, which would be found to disappear when the child was placed in a horizontal position, and extension made upon both limbs. Again, it is not at all difficult to exclude the possibility of hip-joint disease in this case. In the first place, there is an entire absence of the characteristic deformity produced by that affection; and, secondly, no pain is caused the patient by pressure over the region of the joint by the freest possible movements of the femur, or by jamming the head of the latter up against the acetabulum in every direction.

Before making any examination whatever, I felt almost positive that there was no Pott's disease here; for I simply asked the child to pick up something from the floor, and the perfectly natural manner in which she did this convinced me that there was no Pott's disease. If the vertebra had been diseased she would have kept the back in a perfectly rigid condition, and reached the object by flexing the lower extremities alone. But, not content with this test, I made pressure upon the child's head, so as to crowd the vertebrae together without causing the slightest pain, while a careful examination along the line of the vertebrae failed to detect any disease whatever.

While we have all this negative evidence excluding other affections, we find as positive proof of the existence of spina bifida this broad, distinct tumor, situated in the lumbar region of the spinal column, with a central portion where the bone is lacking, and where there is marked tenderness on pressure. Immediately above and below this point the spinous processes of the vertebrae can be felt with perfect distinctness, and they are found to be unusually broad and flat, which is due, no doubt, to the late period of their ossification.

Now for the mechanical treatment, the object of which, you remember, is simply to protect the parts from all pressure and all possibility of injury until the process of ossification has become complete throughout the entire length of the spinal column. I first slip over the trunk a tightly-fitting knit shirt, similar to that used in applying the plaster jacket in Pott's disease or lateral curvature. Then, having the child held in a firm position, but without suspending her, I pass

a few turns of a plaster bandage around the trunk and pelvis in such a manner as to cover the spina bifida completely, after which I cut off a piece from both the top and bottom of the shirt, and turn the remaining portions over the part covered with the plaster. I then make a few more turns of the plaster bandage outside of all, and finally, before the plaster has had time to set, press in the dressing with my hands on both sides of the tumor, so as to make the covering immediately over it more cup-shaped, and thus protect it the more completely from all pressure whatever. We have thus made a hard artificial roof for the spinal cord and nerves, to take the place of the normal bony one until nature has supplied the deficiency; and if, on account of the child's growth, other similar plaster casings should be required before the process has become completed they can easily be applied in the same manner. A piece of steel or copper plate, of appropriate shape, would answer just as well in such a case as this, if it could be kept perfectly in position; but on account of the difficulty of securing this, I think the plaster decidedly preferable. Internally, we will put the child on a course of phosphate of lime, with a view of increasing the earthy phosphates in its system, and thus facilitating the further ossification of the spinal column.

PSOAS ABSCESS, IN CONNECTION WITH POTT'S DISEASE, OPENED ANTISEPTICALLY.

I have here a child, which was brought to me a few days ago, suffering from a large hernia, as it was supposed, in the left groin. There was some doubt about the diagnosis, however, and as I detected a sense of fluctuation, and found that there was disease of the spine present in addition, I concluded that, instead of an inguinal hernia, we had a psoas abscess to deal with. Since then the mass has become red and shining, proving the correctness of this view, and the time has now arrived when the abscess should be opened. This I propose to do to-day, antiseptically, after the method of Lister, which I consider to be undoubtedly one of the greatest contributions to surgery that has been made in the present century. It enables us to perform with impunity operations which, before the method was devised, were almost certain to terminate disastrously, or, at least, to be followed by the most severe constitutional disturbance, on account of the deposition upon the exposed tissues of deleterious germs supposed to be floating in the atmosphere. Mr. Lister, as you know, proposed, by means of a carbolic spray, directed throughout the operation upon the parts on which it was performed, to destroy all germs that could possibly reach them from the air, and at the same time protect them from infection from other sources by having the surgeon's hands and instruments washed in a solution of carbolic acid, and by employing nothing but carbolic materials in the dressings to be applied afterwards. In other words, the part is to be absolutely protected, both at the time of the operation and afterward, until the process of healing is completed, from all air that is not thoroughly charged with carbolic acid. The practical result of this admirable method is that we not only have no pyæmia, or even the slightest constitutional disturbance, but we almost invariably succeed in getting union by first intention, which is certainly a vast gain on former surgical practice.

In now commencing this procedure here, I first wash

my hands thoroughly in a solution of carbolic acid, one part to twenty, and then the skin over the enormous abscess in the left groin. The carbolic spray from the atomizing apparatus then having been directed upon the part from a distance of about two feet, I make my incision with a bistoury, which, like my hands, has been dipped in the carbolic-acid solution. You see that there is a very large quantity of pus here, and the pressure which is exerted by the abdominal muscles in consequence of the child's crying at first forcibly projects it for a considerable distance in a large stream. Afterwards I squeeze out all the purulent fluid that I can with my hands, and then through the opening made by the knife insert a carbolized drainage-tube, pressing it well down into the cavity. Now, having passed a thread through it, so as to prevent it from slipping inside, I cut it off on a level with the surface. Finally, the Lister dressing is put on, consisting of, first, a piece of carbolized oiled silk covered with paraffine, and outside of this several layers of prepared carbolized gauze, which are secured in position by means of a roller made of the same material passed over the abdomen and around the trunk, and then carried for some little distance down the left thigh. Having now attended carefully to all the minutiae of the operation and the subsequent dressing, I think we have every reason to anticipate a very excellent result in the case.

February 12th (two weeks after the operation). Has been dressed five times since the operation. Temperature has never been over 100° F., nor pulse over 96. Has never complained of any pain, and is now nearly well, the abscess discharging only a few drops.

ON THE AFFECTIONS OF THE MIDDLE EAR DURING THE EARLY STAGES OF SYPHILIS.

BY F. R. STURGIS, M. D.,

Clinical Professor of Venereal Diseases in the Medical Department of the University of the City of New York, etc., etc.

COMPARATIVELY speaking, so little is known respecting disease of the ear in syphilis that I hope the report of the following cases may be of interest to the readers of the JOURNAL. In this paper I shall devote myself to considering the early syphilitic lesions of the middle ear, those occurring in what is so often spoken of as the secondary stage of syphilis, reserving the late aural manifestations for future discussion.

These affections of the middle ear occur in one of two ways: first, independently of any other lesion of syphilis, coming on, so to speak, idiopathically; second, in connection with and extension from symptoms in the pharynx, such as mucous patches or the infiltrations of mucous membranes so common in this stage of syphilis.

The first symptom to attract the patient's attention to his condition is pain; and this is seldom severe, such as we find it at the beginning of an acute otitis media, but of a dull character, with occasional sharp twinges. During this period of the disease the pain is also nocturnal in character, having usually a marked periodicity about it, which at the first blush is apt to mislead the surgeon into the belief of its malarial origin, but the presence of the other manifestations of an early syphilis

will put him on the right track. It is very rarely that these symptoms are absent, but it sometimes happens that the otitis media has not appeared until the eruption of skin and mucous membranes has passed off; in other words, it comes on during the period of repose. Then it is that the nocturnal exacerbation of pain becomes of value in the diagnosis, and the condition of the tympanum in these cases, although not absolutely pathognomonic, is such as should excite suspicion as to its true cause.

Let me illustrate this by Case I.

M. X. gives the following history: Primary lesion, apparent on April 21, 1873, was seated on the right side of the balano preputial fold near the frenum, and attended with well-marked induration. Inguinal glands of both sides were also indurated. By May 16th the ulceration of the initial lesion, which was very superficial, had entirely gone, under the local use of calomel, although the induration there and in the groins was still evident. At this date he presented an erythema syphiliticum on the body, attended with nocturnal hemiparasia, anterior and posterior cervical adenitis, and congestion of the fauces. There were no mucous patches in the throat nor on the tongue. He was then put upon the pil. hydrargyri et ferri, at first three daily, which was afterwards increased to four.

On June 5, 1873, the erythema syphiliticum had entirely disappeared. The induration of the initial lesion and of the inguinal ganglia was growing steadily less. There were no mucous patches in the throat, and the anterior and posterior cervical adenitis had diminished. He now for the first time reported a pain in the left ear of three to four days' duration, said pain extending along the upper and lower maxilla, and becoming worse at night. Upon examination of the left ear, the tympanum was found sunken, succulent-looking, opaque, and without any light spot; the drum-head looked as though infiltrated with fluid. There was no congestion of the vessels. H. D. 3'.

Atropine was instilled into the ear, and the pills hydrargyri et ferri were continued.

On the 9th of the same month, four days later, the following record was made: Pain in the ear has entirely disappeared. Examination now shows the tympanum still sunken, but not so opaque as it was at the previous record, the light spot now commencing to be visible. It has also lost that succulent, semi-soggy look which it had on the 5th inst. H. D. and non-congestion of vessels still remain as before.

Improvement went on steadily as regarded the infiltration, the light spot reappeared, but the hearing-distance and the sunken condition of the tympanum were not materially altered. On October 1, 1873, he had an epileptic attack, probably due to syphilis.

There are some noteworthy points in this case which make it peculiarly interesting. First, there was a very short period of incubation between the appearance of the initial lesion and that of the erythema, — very much below the average. Second, at the period when the earache came on, all the other symptoms of syphilis likely to attract attention to the true cause of the ear lesion were absent; there was no erythema, and there were no mucous patches. It is true that the sclerosis of the initial lesion and of the inguinal glands was still evident, but it is not usual to examine a man's penis and groins to treat an otitis media catarrhalis unless there is good reason to suspect syphilis as a cause; hence the real origin of the trouble might easily

escape notice but for one symptom, and that is the *nocturnal* character of the pain. When we pass on to the physical symptoms exhibited by the ear we experience a slight feeling of disappointment at the almost negative condition of affairs presented. One symptom, however, although *not* pathognomonic, is yet sufficient to cause suspicion and to lead to a careful questioning as to syphilis: it is the infiltration of the tympanum conjoined with absence of vascular congestion. The sunken drum in the case just given I attach no importance to so far as syphilis is concerned; I think it antedated this latter, and that would seem to be borne out by its persistence when the other symptoms had gone; but the infiltration is analogous to what we find in syphilitic lesions of the skin and mucous membranes.

CASE II.

L. M. N. Initial lesion appeared May 7, 1873. Seen by writer on 19th of same month. Record then taken is as follows: Three ulcers on penis,—one on the free border of the prepuce, two in the balano-preputial fold; all on the left side. Those seated in the balano-preputial fold were slightly indurated; that on the free border of the prepuce was not. They were superficial in character, of a red color, and the secretion was thin and scanty. The inguinal glands on the left side were not at all indurated, and only one on the right side.

On May 23d, of the two ulcers in the balano-preputial fold, one had entirely healed, the other one had much improved. This was the only sore which now showed any induration. The ulcer on the free border of the prepuce was also doing well. The glandular enlargement on the right side has entirely gone, and none has appeared on the left side.

On June 13, 1873, the report reads: Ulcers have all healed. Within the past few days has noticed hemierania, a feeling of lassitude, and rheumatoid pains, which come on at night. An examination of the body shows a commencing erythema of the trunk and of the fauces. There are no mucous patches of the tongue, throat, or mouth. A few papules are scattered throughout the hairy scalp, but there is no alopecia. Post-cervical adenitis present.

He was put upon the pil. hydrargyri et ferri, three daily, and on August 18, 1873, the record tells us that the symptoms detailed above had entirely disappeared. He has at the present time some pharyngitis. He also reports a sensation of fullness and tinnitus in the left ear, with deafness of that side. There is no actual pain, but a feeling of malaise. An examination of the right ear shows nothing abnormal. Left ear shows a diminished light spot. Tympanum looks puffy and infiltrated, and is somewhat thickened. Hearing-distance diminished (no record, I regret to say, was made of distance).

Under treatment the light spot became normal in size; the tympanum had lost its soggy look, resuming its usual healthy appearance; and hearing-distance had come back to its normal standard. All this occurred in the course of three weeks.

The chief point of interest in this case is the coexistence of a syphilitic pharyngitis with the trouble in the ear, rendering it probable that the latter was due to an extension of the disease from the throat along the Eustachian tubes to the middle ear. This case differs then, from the first one narrated, in which the

ear affection seemed to come on without any connection with or dependence upon other symptoms of syphilis.

CASE III.

The third case which I have to report is not so uncomplicated as the first two, inasmuch as there was a history of an old otitis media suppurativa. Still I believe that even here we may pick out the symptoms which are due to syphilis and those which are due to the older trouble.

F. G. H. was seen for the first time April 5, 1873. The history he gives is as follows: Initial lesion dates back to May, 1872; the treatment then was purely local. Three or four months afterwards he had slight nocturnal cephalalgia, with sore throat, alopecia, and an eruption (kind unknown) upon the arms and legs. Under internal treatment (probably mercurial) these symptoms disappeared. He has had recurrent attacks of sore throat, for which he has pursued treatment off and on. Four months after his initial lesion the sight of left eye grew dim, but this he is positive took place without any inflammation or soreness. On April 5th he was seen for the first time, when the diagnosis of iritis of the left eye, mucous patches of the tongue, and syphilitic congestion of the throat was made.

He was placed under mercurial inunction, which was later on changed to the internal use of the protiodide of mercury and the instillation of atropine to the eye; he improved up to May 15th, when his disease again became active, as shown by the following note: Tongue has recovered. On the right anterior fauces is a decided ulceration. He complains of a pain in his right ear, of recent date. Upon questioning him closely he says he had a suppurative disease of both ears, but so long ago that his memory does not run back so far.

An examination of the right ear showed the tympanum sunken, and the light spot very much diminished in size. This membrane, besides being sunken, was opaque and soggy-looking; there was some congestion about the periphery and the site of the malleus.

Along the handle of the malleus is an interstitial deposit, crescentic in shape, which Dr. Roosa thought due to an old suppuration, but the present infiltrated look might arise from syphilis. Left ear showed some injection of vessels, the result of syringing. Tympanum is very much sunken, opaque, having a dull, thickened look, and without any light spot. Hearing distance both ears 11". On May 17th it is recorded that the ulcer of the throat is reduced to one half its former size. The pain in the ear has almost all gone. Examination of right ear: tympanum has lost its succulent look, is more translucent, and is slightly reddened. Light spot as at last record. Left ear unchanged. May 20th. Ulcer of throat almost entirely healed up. The ear is nearly free from pain. Right ear: tympanum is more lucent and more normal in look. The crescentic exudation has diminished in size. Light spot dimly visible. Left ear as before.

June 10th. Throat well. Ear entirely free from pain. Right ear: tympanum is sunken and opaque, but without the soggy, infiltrated look that it had before. The light spot is now present. Left ear unchanged. Hearing-distance, right ear, = 12 1/2'; left ear, 10.

According to the usual custom of dispensary and hospital patients, he withdrew himself from further observation, but still not so soon as to prevent his case from being of interest for purposes of study. In the first place, we must bear in mind the existence of an

old suppurative otitis media, which is shown in both ears, and which can be excellently studied in the left ear, which was spared by syphilis. The right ear is attacked, and in addition to the sunken, opaque look common to both ears the tympanum of the syphilitic ear becomes succulent-looking, as if it were infiltrated with fluid, and an exudation takes place, which Dr. Roosa believes is due to the older trouble, but which diminishes very considerably in size as the syphilis improves, and may perhaps have been aggravated by the disease, although not originally dependent upon it.

These three cases of mine resemble in their history and course Cases XIII. and XIV. reported by Dr. Albert H. Buck, of New York, in his capital paper on Syphilitic Affections of the Ear in the *American Journal of Otolaryngology* for January, 1879. The points which I believe, upon further knowledge of these cases, will be found of most diagnostic value are absence of acute inflammation and the infiltrated condition of the tympanum. These are not, I think, common to the ordinary forms of middle-ear trouble, whereas the opacity and sunken condition of the drum-head are.

I offer the reports of these three cases as a contribution towards the better understanding of a class of cases as interesting to me in my special studies as they are to my otological brethren.

16 WEST THIRTY SECOND STREET, NEW YORK CITY.

ON THE PREVENTION OF NEAR-SIGHT IN THE YOUNG.

BY HASKET DERRY, M. D.

A BOY or girl is observed by the teacher, during the early years of school life, to see maps and drawings on the blackboard, across the room, less readily than the other scholars. After a time the parents' notice may be called to the fact, and in a small number of cases the child is brought to the surgeon. Expressions of incredulity are subsequently exchanged for those of astonishment when it is demonstrated to the parents that the child cannot see the largest letter of the test-card across the room, and that his farthest point of accurate vision is perhaps within twelve inches of his eyes. He has, without the knowledge of his family, become near-sighted. A difficulty has been fastened upon him that will act to his serious disadvantage through life, and the tendency to which he may transmit to his children. Though its progress may be modified by following suitable advice, it is now no longer capable of removal. Such cases occur with great frequency.

According to the best attainable statistics, there is found in the United States only about one third as much near-sight as is met with in Europe. And yet its prevalence in New England may be estimated from the fact that one person in ten who consults the ophthalmic surgeon does so on account of this very difficulty.

That near-sightedness is always a serious disadvantage to its possessor, that such an eye is in fact a diseased eye, that the affection is one that tends between certain ages to increase, and that exceptional increase may with advancing years lead to blindness are facts so often insisted on as to have become familiar to all who take an interest in this subject. Few states of the eye have been more accurately studied.

¹ Read before the Boston Society for Medical Improvement, May 24, 1880.

The statistics collected have reached the limit of usefulness. The age at which myopia is likely to begin, the period of life during which it generally increases, the influence of civilization and education on its development, are all satisfactorily known. The hopelessness of its cure is universally conceded. But, in my opinion, far too little study has been bestowed on the possibility of its prevention. It is to this branch of the subject that I briefly invite attention.

The first question that arises, then, is as to whether prevention is possible. In answering this, two facts are to be taken into consideration: *First*, that near-sight is seldom, if ever, congenital, though a tendency to its development may undoubtedly be inherited. *Secondly*, that it is usually a product of civilization. This view receives support from those who have had the opportunity of examining the eyes of savage tribes. Farnari, among others, found no near-sight among the Kabyls. Macnamara states that he, some years ago, was among the Southals, the aborigines of Bengal, dwelling among the Rajahmahal hills. "I took," he says, "every opportunity of examining the eyes of the people I was brought in contact with, for the purpose of discovering if myopia and such like diseases existed among them, but I never yet saw a young Southal whose eyes were not emmetropic" (that is, perfect). Other testimony is in the same direction.

The following is a brief summary of our knowledge regarding the appearance and progress of near-sight:—

It is not generally found at all among children who have not commenced school life.

Between the ages of six and seven some three school-children in a hundred are found, in this country, to be near-sighted.

This percentage steadily increases, and at the age of twenty at least twenty-six in a hundred are thus affected. The percentage rises to forty-two in Russia, and to sixty-two in Germany.

Other things being equal, the children of near-sighted parents are more apt to acquire near-sight than are those whose parents have normal vision.

The development of near-sight is furthered by the following causes.

- (1.) Work by insufficient light.
- (2.) Work on minute objects, such as fine print, intricate maps, and the like.
- (3.) Work in a constrained or stooping position.
- (4.) Continuous study, and
- (5.) Prolonged or excessive study.

The action of this last is well illustrated by an example given by Erismann. Four thousand three hundred and fifty-eight scholars being in the habit of studying out of the regular school hours, he found

Of those studying two extra hours 17 per cent. were near-sighted.

Of those studying four extra hours 29 per cent. were near-sighted.

Of those studying six extra hours 40 per cent. were near-sighted.

Such being the causes of near-sight, a large portion of the success that is likely to attend its prevention would depend on their judicious elimination. So much has already been written on this subject that it is needless to reiterate the advice given from every quarter. The necessity of well-lighted rooms, of clearly-printed text-books, of properly constructed desks and seats, has been clearly dwelt upon. The subject of prolonged study must be left to those more familiar than myself with the forcing system of modern educa-

tion. A single word may, however, be permitted regarding the continuous use of the eyes in young children, and the mechanism of the production of near-sight.

A normal eye becomes myopic, of course, by growing longer, by the bulging out of its posterior segment. There is excellent authority for believing that this is peculiarly apt to take place in the children of near-sighted parents. They inherit a diminished power of resistance in this part of the organ of sight. The length of the eye may be normal at birth, but the scleral tissue of its posterior half is unduly elastic, and gives way more readily than it ought, during the period of development of the body. After this time is passed it may acquire new strength, and cease, after the twentieth year, to be liable to give way. Let us bear this tendency in mind, and remember, moreover, Eulenburg's statement that ninety per cent. of curvatures of the spine, which do not arise from a special disease, are developed during school life. If now, in the case of a growing child, a constrained and unnatural position, long continued, may cause malformation of so solid a structure as the vertebral column, why may not a similarly constrained position (so to speak) of the eye cause a change in the shape of that organ? A bow must be kept unstrung to retain its elasticity. The continued effort of accommodation for near objects is accomplished by the change in shape of the crystalline lens from its least to its greatest convexity. And just as the bow, too long or injudiciously stretched, fails to regain its pristine shape, so does the crystalline, overstrained or fatigued, often refuse for a greater or less time to relax into the shape of rest, when the eye is sought to be adapted for only distant objects. This inability to relax we call "cramp of the ciliary muscle," "spasm of the accommodation," and it is the first step in a downward course.

Now one of the principal factors in bringing about the change of shape or lengthening in the posterior segment of the globe is this very exercise of the accommodation. It probably acts by throwing the choroid into a state of tension and inducing congestion. The eyes, therefore, used so continuously as to undergo spasm of the accommodation, are even more likely to become near-sighted than those in which the accommodation is relaxed as soon as near objects are no longer regarded.

Near-sight may then begin with spasm of the accommodation. A single case will serve as an illustration of this fact.

I examined the eyes of a student at Amherst College, at the commencement of his freshman year, in November, 1875. He presented himself towards the close of the day; the afternoon was a dark one, and he had just been reciting. There was a slight degree of near-sight in each eye. In October of the next year I examined him again, and found his near-sight entirely gone. He had been laboring under accommodative spasm. But in June, 1879, at the completion of his college course, true near-sight, to a considerable amount, had made its appearance, and the ophthalmoscope showed it to be real, and not due to spasm.

This case is of great interest as illustrating the theory that near-sight frequently commences in the above manner; how frequently cannot at present be estimated. According to many, such cases are the rule; others think them the exception. But allow the fact

that they do exist, and we have an important clew to the prevention of near-sight; for this spasm or cramp of the ciliary muscle yields readily to appropriate treatment. How often do we hear complaints from children that, after studying a time, distant objects appear blurred and indistinct! They can no longer tell time by the clock across the room, no longer make out figures on the blackboard. Such cases are often brought to the ophthalmic surgeon. With some of the children the spasm has already disappeared. With others a rest of a few days suffices to remove it. Others, again, require to be put under the full influence of atropine, to which, sooner or later, the thing must yield, as in the following instance:—

E. S., at the age of twelve, had never considered himself near-sighted. Both parents have normal vision. His brother, aged seventeen, who came under my care at the same time, had a considerable amount of myopia, which up to the present has gone on steadily increasing. His sister, slightly older than himself, is similarly affected. In March of this year E. S. came to me again, complaining of pain in eyes on use, and inability to see distant objects distinctly. He was now near-sighted, and could not see sharply any object removed more than thirty-nine inches from him. I kept him three weeks under atropine, and the near-sight entirely disappeared, he being able, according to his own expression, to see as far as ever. We are warranted in the supposition that, had the difficulty not been recognized and the treatment employed, he would, like his brother and sister, have become near-sighted for life.

Assuming, then, as we are amply justified in doing, that cramp of the ciliary muscle is the first step in the development of near-sight in a number of cases, and knowing that the spasm, as such, is readily curable, the desirability of watching for its occurrence becomes evident. In fact, the extreme importance of recognizing all near-sight in its very earliest stage has been far too little insisted upon, for it is at this precise period that so much may be expected from judicious treatment, as well as from careful regulation of the child's habits, method of study, and length of time spent in school.

Unless measures be taken to prevent it, the percentage of near-sight among us is liable to increase as time goes on, largely through the transmission of the hereditary tendency.

What course shall be adopted to prevent this? I would suggest the following plan: Let all children have their vision tested as soon as they know their letters; let a careful record be kept of the result; have the examination repeated at least twice a year during the whole of school life; and let near-sight be promptly treated as soon as its commencement is detected.

The school committee of Boston, for instance, might adopt some such plan as the following: A brief document, couched in popular terms, could be circulated among the teachers in the public schools, explaining the views just rehearsed, and giving instructions in the use of the test-types of Snellen or Monoyer. Each school should be provided with one or both of these cards, the price of which is trifling. The card itself should be hung in a room of sufficient length, and illuminated artificially at the time of examination, thus securing uniform intensity of light on every occasion. At its entrance into the school each child should have its vision tested by the card, in each eye separately,

and a record kept of the result. This examination might be repeated at least once in six months during school life, and any change noted.

Thus far the whole matter may safely be left in the hands of a tolerably instructed teacher. If, now, a child, that has previously had perfect sight, is observed to see less and less on successive trials, the assumption is that near-sight is commencing. The family should now at once be notified, and advised to apply to their physician. With the instruction in ophthalmology now given in our leading medical schools, it will be easy for him to carry the examination farther, to recognize the presence of near-sight, and to prescribe the necessary rest or atropine treatment, that, if the case has been taken in time, will restore the eye to its normal condition. If the myopia refuses to yield to atropine, and in moderate amount has to be accepted as a life-long disadvantage, suitable advice will certainly modify its progress.

If sufficient interest can only be awakened in the subject, and if this course be followed, I do not see why the amount of near-sight in the community may not ultimately be considerably diminished. Let the absurd traditions of the past, that myopia is due to an increased convexity of the eye, and is even an evidence of strength of sight, be once fairly banished from the popular mind. Let it be insisted on in season and out of season that near-sight is a disease, a product of civilization, arising generally during school life, often curable if promptly met, always incurable and even progressive if neglected, invariably a disadvantage to its victim, and sometimes in later life fatal to sight; let these facts be fairly brought forward and understood, and the next generation will have better and stronger eyes than those of the past, and that of the present.

There will be no near-sighted children turned out by the schools of Dr. Richardson's City of Health.

RECENT PROGRESS IN SURGERY.

BY H. H. A. BEACH, M. D.

ACCESSORY THYROID GLANDS.¹

MADELUNG teaches that accessory thyroid glands are independent of the thyroid body, or simply attached to it by a vascular pedicle, and, contrary to the opinion of Rokitsky,² congenital.

The appearance of the normal accessory glands is like that of ganglions. Their form is spherical, ovoid, or cylindrical, while their volume varies from the size of a pea to that of a bean. Gruber³ has found some superior glands from four to five centimetres long. They may be divided into superior, inferior, lateral, anterior, and posterior varieties. The superior glands are usually placed on the median line or a little to one side, in the space between the superior edge of the isthmus and the hyoid bone. Their capsule is commonly bound by ligamentous bands either to the thyroid cartilage or to the hyoid bone. Isolated lobules have been rarely found above the hyoid bone; the author reports two cases.

The lateral glands are found along the borders of the thyroid body, and have been observed in the triangles of the neck. The anterior are rare; the author

quotes but one case, that of Mr. Poland,⁴ with serious trouble in deglutition, phonation, and respiration. The inferiors are found below the isthmus, upon the median line or upon the sides of the trachea. Finally, the posterior glands, of which several cases are reported, claim an especial interest, on account of the compression which they exercise upon the trachea and oesophagus.

The accessory glands can undergo alteration independent of the thyroid body, but the simultaneous alteration of both forms of gland is very rare. All the varieties of goitre have been observed in the accessories, but the cystic is most common. The author suggests the possibility of the latter form being identical with hydrocele of the neck. Hereditary influence is doubtful; in only one case the mother of the patient had goitre. Accessory goitres are, like goitres of the thyroid gland, enveloped by a net-work of largely dilated veins, which distinguishes them when doubts as to their nature are raised by their location. They show a preference for the right side of the neck and the female sex; usually appearing at puberty or earlier, and growing slowly, until they may suddenly occasion trouble in deglutition and respiration. By compression they may cause a partial atrophy of the thyroid body;⁵ and softening of the tracheal and laryngeal cartilages is produced by them to such an extent as to close both passages, even after the removal of the tumor.⁶ The diagnosis of accessory goitres is always difficult; in making it, their mode of development should be investigated.

The author describes a case where, supposing that the tumor was a lymphoma, he cut down upon a hypertrophied accessory gland enveloped by a net-work of veins. In a case communicated to him by Lücke, death followed in the train of inflammation and suppuration of a posterior accessory gland, unappreciated during life and discovered at the autopsy.

The goitrous nature of the tumor recognized, it should be ascertained if a pedicle connects it with the thyroid body. Here the author cites a case from Briere⁷ in which a pedicle of two fingers' breadth was not found until the removal of the tumor. It should be remembered that goitres send prolongations in all directions, even to the lower jaw and mastoid process, which do not follow movements impressed upon the principal tumor; otherwise we shall be exposed to diagnostic errors, of which the Arch. gén. de Méd., 1875, ii., page 233, contains a striking example.

Glandular masses which belonged originally to the thyroid body, and have become more or less separated from it by some pathological process, may be called acquired goitres. They are never so clearly separated from the thyroid body as are the true accessory goitres.⁸

In a majority of the cases of accessory goitres the thyroid gland itself has undergone little or no change, while in the cases of acquired goitres the disease has involved that gland.

Upon careful palpation of the thyroid body, a depression may usually be found, whence the tumor has sprung.

The growths which follow degeneration of the thyroid body are alone amenable to parenchymatous injection. Madelung advises that as a precautionary measure tracheotomy should be done before an injection is employed. Excepting posterior tumors, extirpation of accessory goitres does not in general offer great difficulty.

ANÆSTHESIA BY BROMIDE OF ETHYL.

The profession is already familiar with the details of the earlier experiments made with this drug, and recently their attention has been directed to it by the death attributed to its employment, by Dr. J. Marion Sims. His theory of the cause of death (from the poisonous action of the agent) is not accepted by Dr. Lewis, who has used the anæsthetic between two and three hundred times, without bad symptoms, in operations not lasting over forty minutes. If Dr. Sims's evidence is not conclusive as to the cause of death, it must be conceded that he presents strong testimony for warning the profession of a drug that may prove, upon additional experimentation, to be more poisonous than chloroform or bichloride of methylene. It remains to be seen whether, from the comparative ease attending its administration, patients will be submitted to its influence while the death-rate is undetermined, or if experiments upon the lower animals are to demonstrate its toxic effects. It is fair to conclude that tests on the human subject, justifiable before the days of sulphuric ether, are no longer so, since the necessities, if not the luxuries, of anæsthesia are already provided for.

THE TREATMENT OF TRANSVERSE FRACTURES OF THE PATELLA.

At a recent meeting of the Medical Society of London, Mr. Rose presented two cases of transverse fracture of the patella by muscular action, with separation of the fragments, treated by him at the Royal Free Hospital. He cut into the joints antiseptically sixteen days after the injury and wired the fragments together, as first performed by Dr. Cameron, of Glasgow. Antiseptic dressings were afterwards applied. In the first case, the temperature never rose above 99° F. nor the pulse above 90. The dressings were changed eight times; horse-hair drainage was employed, and the last hair was removed on the twentieth day after the operation. The wires were cut down upon and taken out on the sixth week. The details of the second case were about the same as those of the first. In the latter, movement at the knee-joint was limited; in the former, the patient could bend his knee to a right angle, walk up stairs and had evidently free use of the rectus muscle. It was thought that bony union had taken place in both cases. In the discussion which followed, the propriety of performing the operation in recent fractures was questioned by Messrs. Bryant, Henry Smith, and Amphlett. Mr. Bryant considered that the result in the second case was very good, but in the first not equal to results in cases he had seen treated in the usual way. He would divide fractures of the patella into two classes, old and recent. In the former, where the limb is almost useless, it is justifiable to run some risk in order to cure the patient. In recent fractures, however, where the grave consequences of opening the knee-joint are dependent upon the protection afforded by a Lister dressing *carefully* applied, exceptions were taken. Mr. Lister and Mr. Rose advised the performance of the operation in recent cases rather than wait until the rec-

tus muscle has had time to become weaker and shorter, and the usefulness of the limb impaired. Mr. Lister strongly deprecated the adoption of this operation by any surgeon who did not fully understand the antiseptic treatment, and thought it wrong to do the operation in old cases as well as in the recent, unless the surgeon was morally certain that decomposition would not follow the operation. If that risk were abolished, it was the surgeon's duty to treat recent fractures in the same way as old ones, it being the only treatment holding out a certain prospect of a good result in all cases.

INGUINAL CASTRATION IN RETAINED TESTICLE.¹

Monod and Terrillon in their memoir on this subject conclude that it is not a dangerous operation. In fifty cases, peritonitis occurred three times, and only once resulted in death. The operation is easy, and is indicated when the testicle is painful, or the seat of grave inflammatory processes (false strangulation).

Hospital Practice and Clinical Memoranda.

A CASE OF TETANUS: RECOVERY AFTER SEVEN WEEKS.

BY C. C. FIELD, M. D., LEOMINSTER.

FEBRUARY 20, 1880. C. K., aged thirty-eight years, of great muscular strength and in robust health, temperate, a manufacturer of combs, while sawing horns received a severe blow upon his right eye by a horn, thrown with great force in a slanting upward direction from a rapidly revolving circular saw, crushing the eyeball up against the upper floor of its socket. There was also a wound in the lower eyelid, an inch and a half long, parallel with its edge and penetrating the cavity containing the eye. Great swelling and ecchymosis soon followed, but not much pain nor febrile action at any time afterwards. A compress wet with cold water was applied to the injured part, and retained there. Four days afterwards (February 24th), Dr. B. Joy Jeffries, of Boston, saw the patient, and thought the eye injured beyond reparation, probably, though, on account of the great swelling, its exact condition could not be ascertained. He advised a continuance of the cold compress, the bowels to be kept open, and the removal of the eyeball if the uninjured eye become affected sympathetically. On the eighth day after the injury (Friday, February 27th), in the night, tetanic symptoms were first manifested by violent contraction of the diaphragm, supposed to be an attack of cramp in the stomach, tetanus not being suspected. This was relieved by the subcutaneous injection of one sixth of a grain of morphia. On Saturday and Sunday, the two following days, the patient complained of a feeling of "lumpiness" in the muscles of the jaw, and the next morning trismus was fully developed. The following day, Tuesday, March 2d, the injured eyeball was removed by Dr. Dennett, of Boston.

At the onset of the trismus the prescription was ten grains of chloral hydrate and ten grains of bromide of potassium alternately once in two hours, and the medicine was taken accordingly. Tonic spasms as they occurred were relieved by hypodermic injections of morphia and by friction with the hands. This treatment was continued through the first and second weeks of the disease.

¹ Arch. gén. de Méd., March, 1880.

During the first four weeks the muscles of the trunk — back, neck, and abdomen — were in a state of rigid *clonic* spasm, drawing the head backward and preventing the body from bending forward. For the same time and through a part of the fifth week violent and very painful tonic spasms affected different muscles of the body and limbs more or less frequently, sometimes slight and relieved by friction, at other times violent, requiring for relief the injection of one eighth to one sixth of a grain of morphine hypodermically. It is a noticeable fact that the tonic spasms occurred in the muscles of the upper part of the body — the arms (not the fore-arms) and neck — and the diaphragm during the first two weeks, and of the lower limbs and back the third and fourth weeks and a part of the fifth.

At the end of the first week (Friday, March 5th), Dr. C. D. Homans, and six days later (Thursday, March 11th) Dr. Calvin Ellis, both of Boston, saw the patient with me in consultation.

Until this time, near the end of the second week, the pulse had been about 84, and the temperature not sensibly elevated above the normal standard. The bromide and chloral had been given without intermission, as at the accession of trismus, and the injections of morphine and friction were resorted to when the tonic spasms required.

The day following the consultation with Dr. Ellis (Friday, March 12th) the patient, having taken ten grains of chloral once in four hours — sixty grains a day — for twelve days, began to show signs of increasing debility, requiring more help in being moved in the bed or from it; his pulse also became more frequent, rising to 96 at noon, 108 in the evening, and 120 at two o'clock in the night, with Cheyne-Stokes respiration.

The question was forced upon our minds whether the present state of the patient was caused by the protracted use of the chloral, or by approaching dissolution. To solve the doubt the use of the chloral was suspended at once, and the next morning the pulse had fallen to 108, at noon to 96, and at night to 84, as before, at which rate it continued until approaching convalescence. For the chloral omitted the subcutaneous injection of morphine — one eighth to one sixth of a grain — once in eight hours was substituted; and after two days, as the quieting effect of the morphine did not last to the end of that time, six or eight grains of chloral were given four or five hours after the morphine. This small quantity had the desired effect. The bromide, morphine, and chloral were continued in this way through the third week, with considerable abatement of the force and frequency of the tonic spasms, and we began to entertain hopes of the final recovery of the patient. But in a day or two afterwards, on Sunday, March 21st, at the beginning of the fourth week, the patient was seized with extremely violent and painful spasmodic contraction of the muscles of the whole body, — trunk and extremities, — with impending asphyxia, the face being livid, from the spasm of the respiratory muscles. A quarter of a grain of morphine was injected under the skin; brisk friction with the hands was kept up on his back and limbs, and mustard applied over the epigastric region. After thirty or forty minutes this spasmodic action ceased. Thirty-six hours afterwards (Monday night) there was a similar but not so severe attack.

Noticing an article in the JOURNAL of April 17, 1879, in regard to the use of arsenic in the treatment of tet-

anus with apparent good results, by Dr. Hodgen and others, of St. Louis, Mo., the administration of five drops of Fowler's solution once in two hours was commenced, the bromide, chloral, and morphine being continued as before. After a week (Sunday, March 28th), on account of an evident increase of the "purty" or bloated appearance of the face, so common in tetanus, the Fowler's solution was omitted, and during the week (the fourth) there was marked diminution of the tonic spasms. Two days later (March 30th) there was an attack of severe cramp in the lower part of the back and legs, and Thursday (April 1st) another similar attack. The solution was again prescribed, and continued through the remainder of that week (the fifth), the sixth, and in diminished doses the seventh. There were no tonic spasms after the administration of the solution was resumed, and the rigidity of the muscles of the back began to relax, so that the patient could bend his head and shoulders forward. In the sixth week the clonic spasms of the masticatory muscles began to yield, so that at the end of that week he could put three fingers into his mouth and feed himself with a spoon. During the seventh week the arsenical solution, morphine, chloral, and bromide were continued, but in smaller doses and at longer intervals, and then omitted, except a small dose of morphine at night for a week or more. At the end of the seventh week he could masticate his food as usual, and was in every way convalescent; and on May 17th, after twelve weeks, his recovery was perfect.

During the first four weeks the tongue of the patient was bitten by the sudden snapping together of his jaws on suddenly awakening from sleep, particularly when under the influence of chloral; for in that state the muscles of the jaw would relax sufficiently to let the end of the tongue slip in between the teeth. This was in some degree avoided by gently rousing him when sleeping too heavily.

Particular pains were taken from the beginning to keep the patient well nourished. While the jaws were closed the nourishment was liquid, such as milk, good gruel, broths, and beef tea, and was taken through a "drinking cup," the small end of which was applied between the teeth, or rather against the narrow space between the teeth that existed, but not of sufficient width to admit it. At first the gruel and broth were strained, as the smallest particle of meal or meat between the teeth excited spasms; but later in the disease, when there was some relaxation of the muscles, or at least less tendency to spasmodic action, rice boiled very soft was added to the milk, and finally chopped meat to the broth. For the first four weeks nourishment was given in this way every second hour; afterwards, when the patient could take rice and meat, prepared as above stated, with the milk and broth, the interval between the meals was three hours. As convalescence advanced there was a return to the usual kinds of food and times of eating.

For the first three weeks the bowels were kept open by gentle laxatives, mostly by a compound infusion of senna, figs, and ginger every second day. In the third week, when a defecation took place, there was excited, strong spasmodic action of the abdominal muscles, with violent and painful bearing-down effort, like the expulsive pains of parturition. Laxatives were abandoned, and a copious enema of warm water was given every morning thereafter till convalescence, with satisfactory results.

At the request of the patient, on Sunday P. M., March 21st, subsequent to the attack of spasms with asphyxia, before described, he was placed in a warm bath with gratifying effect. The next day he had the bath again, but it excited some spasmodic action, and was not repeated.

Besides the medication mentioned above, various applications were made externally, such as mustard plasters to the back and stomach, and fomentations of hops, lobelia, and tobacco upon different parts of the body, the good effect of which was questionable. During the tonic spasms brisk and thorough rubbing of the skin with the hands, conjoined with some oily substance for lubrication, thus preventing the skin from being partially denuded of its outer covering, seemed to be the most efficient external application. The patient, in extreme suffering from the tonic spasms, would call upon the attendants to "rub *hard*, rub *hard*;" and this thorough and long-continued friction threatened abrasion of the cuticle. Among the many domestic remedies — "sure cures" — recommended by friends, "turtle's oil" was one, and this was used most of the time for the inunction. By reflex action, the nerves of the skin being soothed in this way, the spasms seemed in some degree to be allayed.

The patient had most excellent care and comfortable surroundings, intelligent and faithful attendants watching over him day and night; and to this, in no small degree, may be attributed the successful termination of the case.

LEOMINSTER, May 17, 1880.

Reports of Societies.

PROCEEDINGS OF THE BOSTON SOCIETY FOR MEDICAL IMPROVEMENT.

T. M. ROTCH, M. D., SECRETARY.

MAY 24, 1880. DR. JAMES C. WHITE, permanent chairman, presided.

PREVENTION OF NEAR-SIGHT IN THE YOUNG.

DR. H. DERBY read a paper on near-sight, which will be found on page 533.

DR. WILLIAMS thought it important that attention should again and again be called to this subject; because the community is so slow to believe in the serious dangers which are now known to attend the excessive use of myopic eyes in study. The ophthalmoscope reveals great and progressive changes, previously unsuspected, in the most important structures of the eye, which are solely caused by continuous accommodation of the sight for small objects, and which, unless arrested, tend to deterioration and even loss of vision. Unfortunately, children who have become near-sighted generally find their chief pleasure in books, and are disinclined to the sports of other children, because they do not see objects around them so well as their fellows. The parents and teachers of such children, pleased with their precocious diligence, are but too ready to encourage excessive application to study and efforts to gain a high rank at school; especially, as for the time no complaint is made of the eyes. It is only when the myopia has reached a degree which will in the future render them incompetent for many pursuits, and especially for those requiring constant use of the eyes, to which they had hoped to devote themselves, and

when, perhaps, much use of the eyes already begins to cause pain, that it is discovered, too late, what a mistake has been made.

Prevention of further increase of myopia, being the only resource against certain misfortune, it becomes of the utmost importance, as a matter of public hygiene, that children, and especially girls, who already have a considerable degree of myopia should not be allowed to attend school after having completed such studies as are necessary for some vocation which will not greatly tax the eyes. They should abandon all efforts to acquire what is termed a higher education, so far as this involves close application of the eyes, because, in attempting this, myopes not only imperil their sight and their future well-being, for the sake of obtaining knowledge which they cannot afterwards make available, but they also create for their children a hereditary tendency to the same disease.

DR. H. P. BOWDITCH remarked that Dr. Derby's paper opened a field for an instructor in hygiene in the schools, and it was a matter of reproach among the physicians who were on the school board that some movement had not already been made in this direction; he thought that the schools would be greatly benefited by such an instructor.

DR. WADSWORTH agreed with the previous speakers as to the importance of the subject. Not only among the poorer classes was progressive short sight too little heeded; it was by no means an uncommon occurrence for parents of means and education to bring their children to the oculist only when the myopia had already reached a very considerable degree.

He said that there was one direction in which it was at present in the power of the school committee of Boston to make a change which could not fail to be of advantage. He referred to the subject of maps. In the geographies now used in the schools many unnecessary names of towns, rivers, etc., are set down on the maps; then the line of the coast is "shaded" by a series of parallel lines, to make the maps look prettier. The result of all this is that the names of places must be printed in quite small type, must often be printed across or among the lines shading the coast, and, in consequence, a great strain of the eyes of the children is necessitated in the effort to find the places sought. The search for a single name on one of these maps is often an exceedingly trying task for a child's eyes. This was not simply a matter of theory, but he spoke from repeated personal observation in his own family. If the committee would demand simpler maps, with fewer names of places and no shading of coast lines, both time and effort would be saved to the children, and one of the evil influences of school life causing near-sight would be removed. As for the matter of expense, such maps as suggested would cost less rather than more than those now in use.

PSEUDO-MUSCULAR HYPERTROPHY.

DR. J. J. PUTNAM showed a typical case of pseudo-muscular hypertrophy in a boy of ten years, the disease being of several years' duration.

Not only were the muscles of the legs and thighs, back, scapula, and upper arm involved, but the tongue was unusually broad and thick, and the lines of the face were thickened and dense.

No cause could be discovered either in his own or his parents' antecedents.

In speaking of the pathology, Dr. Putnam said that

he thought this affection was probably related to the so-called "hereditary form" of the progressive muscular atrophy, and much less closely, if at all, related to the usual adult form of that disease.

CEREBRAL HÆMORRHAGE AND FIBROUS TUMORS OF UTERUS.

DR. SHATTUCK reported the case. M. S., sixty years of age; profuse uterine hæmorrhages at the age of forty-two; for ten or twelve years continued to menstruate. She consulted an eminent gynecologist twelve years ago, who examined her, and said, "My good woman, I can do nothing for you, and before many weeks pass the undertaker's cart will stand before your door." She never gave up work but for a day or two at a time. During the last six weeks no uterine hæmorrhage. Four years ago profuse epistaxis. In October mental aberration for two weeks; January 8, she was better and stronger than for years. She felt very well on Monday, May 17th, doing her washing easily. At four o'clock in the afternoon numbness of left arm; at six P. M. numbness and loss of power in left leg. On Tuesday pain in head and limbs, but no affection of speech or intellect. On Wednesday coma, from which she could be roused for a short time. Her death was easy and quiet, on Friday evening, four days after the attack; there was a loss of consciousness during the last two days.

DR. CUTLER exhibited the specimens. There was extreme atheromatous degeneration of the arteries at the base of the brain, the change extending to the minute subdivisions of the vessels in many instances. A careful search did not reveal the presence of an embolus. The convolutions were flattened, more especially over the right convexity, though the left was also affected, but to a less degree. Atrophy was noticed on the left hemisphere in a small area near the longitudinal fissure, directly behind the fissure of Rolando. On section it was found that hæmorrhage had occurred into the substance of the right hemisphere at a point vertically under the angle of junction of the fissures of Rolando and Sylvius. A clot the size of a small hen's egg was turned out. The great centres were apparently healthy.

The uterus contained a large number of small interstitial and submucous fibrous tumors, which had undergone a greater or less degeneration. One polypoid tumor completely plugged the os internum. Some of the largest tumors contained deposits of lime salts.

EMPHYEMA: ANTISEPTIC OPERATION.

DR. J. B. AYER read a case of emphyema occurring in the prostate.

The patient, a girl, three and a half years old, previously healthy, was attacked with acute bronchitis early last February. Before recovering from the attack, which was of ordinary severity, an effusion insidiously formed in the right side of the chest, and four weeks after the commencement of bronchitis the right pleural cavity was found to be distended with fluid.

During the following thirty-five days I endeavored to remove the effusion by the energetic use of hot poultices, iodine ointments, diuretics, and laxatives, at the same time keeping up the patient's strength by tonics, stimulants, and nourishing food. In the first ten days of this treatment the fluid was gradually undergoing absorption, but after that time no further improvement was noticed, and later the amount increased.

Examination of the chest with Dr. F. C. Shattuck, April 7th, revealed flatness over the right lung except at the summit. The apex beat was found one quarter of an inch outside of the line of the nipple. There was immobility of the right side of the chest and absence of vocal fremitus. We agreed that surgical measures ought not longer to be deferred.

April 8th, Dr. Warren (Dr. Shattuck and Mr. Ballard being present) aspirated in the sixth intercostal space in the line of the axilla, and finding pus, immediately made a free incision, one inch long, through which came, with a gush, over twelve ounces of thick, odorless pus. A rubber drainage-tube was inserted and attached to the sides of the wound, and a long ligature sewed to the tube was allowed to fall outside.

Dr. Warren did not think it advisable to syringe the chest. The operation was performed under carbolic spray, and the full antiseptic dressing applied and bound in place by several long bandages. Very little ether was given, as the child did not take it well.

Twenty-two hours after the operation the dressings were changed. During this time additional bandages were twice applied, on account of serous oozing. She began to rest upon the healthy side. The temperature had fallen to 98.2° F., pulse to 114, and respiration to 35. The change was made under carbolic spray, with assistance of Mr. Ballard. The discharge was found to consist of odorless, bloody serum, entirely free from pus. During the following twenty-four hours there was less serous discharge, but there was sufficient to require a change of dressing. Four days later the third change of dressing was made; there had been but slight discharge from the wound, and there was no flow through the tube on removal of the dressing. A few drops of thin pus were noticed on the protective.

At this time she was troubled with a severe cough, which proved very obstinate, and distressed her eight days, resisting all treatment. Examination of the chest showed that the cough was due to bronchial affection and that both sides were alike involved. The pulse during this time was about 140; the temperature fluctuating between 99° F. and 103° F., and respiration between 60 and 70.

The fourth and fifth changes in the dressings were made at intervals of three and seven days, Mr. Jaques kindly assisting. At the fifth dressing it was found that the drainage-tube had been drawn within the pleural cavity, and that the opening in the chest had partly closed. With difficulty the tube could be brought within reach of the dressing forceps by pulling tense the silk guide. One teaspoonful of odorless pus followed the withdrawal of the tube. The tube was shortened and reintroduced. At this time the cough had disappeared, and the child was making rapid improvement.

Ten days later the dressing was changed for the sixth time. She had been fretting a little about the arm, which was still confined to the side by bandaging. The cause of discomfort proved to be an abscess in the axilla, which broke during this dressing, and discharged freely.

Three days later the dressing became disarranged from poulticing the abscess and from walking about (it was warm weather, and I had allowed her to go out-of-doors), and required changing.

I found that the drainage-tube contained a plug of fibrin, showing that it must, for a brief period, have come in contact with the air.

I removed the drainage-tube at this time, and dressed the wound as before. I think it would have been safe to have removed the drainage-tube several days earlier, as there was only a few drops of discharge from the wound daily.

Eight days later, when the dressing was removed, it was found that the wound had healed. This was the thirty-eighth day after the operation, and seventy-third day after the discovery of the presence of the effusion.

The lungs now show no sign of disease. Normal respiration is heard throughout, and the slight dullness which has been heard at the right base is rapidly disappearing. There is no difference in measurement between the two sides of the chest. The child is rapidly gaining strength.

It is worthy of especial mention that not more than two drachms of pus came from the wound after the operation.

ECZEMA.

DR. BETHUNE read a paper on *Ecze-ma* and its Relations, which will be published.

INTESTINAL OBSTRUCTION.

DR. FIFIELD reported two cases of intestinal obstruction, one of which, after existing for twenty-four hours, was relieved by full doses of belladonna and Epsom salts, given alternately every two hours.

The second case was a woman, in whom the obstruction had existed for two weeks, and where the diagnosis of lead poisoning was made by the attending physician.

The coils of intestine were plainly seen contracting beneath the abdominal wall, and Dr. Fifield, having been called in consultation, at once made the diagnosis of intestinal obstruction. Belladonna and Epsom salts were also given in this case, but without effect. Dr. Fifield then operated, making the incision according to Nélaton. The patient died. — DR. MINOT said that he could see why the belladonna was given in the second case, but that he did not understand why the Epsom salts were given, as the intestines were already contracting excessively.

DR. FIFIELD said that he had given the salts at a last resort.

DR. HODGES asked Dr. Minot why he thought that the belladonna should be given.

DR. MINOT answered merely as a hypnotic, just as he would have given opium, and that considerable relief can be obtained by aspiration in these cases. — DR. WARREN remarked that Dr. J. Hutchinson had written a paper on this subject some years ago, advising manipulation after complete etherization. He also mentioned the case of a new-born infant, which he had seen in consultation with Dr. J. B. Ayer, where complete relief was obtained after etherization.

THE PENNSYLVANIA STATE MEDICAL SOCIETY.

The session of this year was held at Altoona, on the eastern slope of the Allegheny Mountains, at the head of the Logan Valley, on the main line of the Pennsylvania Railroad, about nine hours' ride from Philadelphia. It is at this place also that the railroad company has its most important construction and machine shops. Altoona boasts a large hotel, the Logan

House, which is first-class in its appointments, and is owned by the Keystone Hotel Company. It is twelve hundred feet above the sea level, and, although warm enough during the day, is cool and comfortable at night. Hay fever is said to be unknown. Among the excursions is one to Cresson Springs, fifteen miles from Altoona, which is a popular place of summer resort, twenty-two hundred feet above the sea, beautifully situated, near the Pennsylvania Railroad. Between Altoona and Cresson are the famous horse-shoe curve and the Gallitzen tunnel (seven eighths of a mile in length). Another trip is by the Bell's Gap Railroad, an offshoot from the main line, about eight miles below Altoona. This little road is narrow gauge, and as the diminutive train meanders along the mountain side, and creeps over astonishing trestle-bridges (like a cat walking an exceedingly high fence), the panorama of mountain scenery is wonderfully grand and impressive. The grade of this road is on an average one hundred and fifty feet to the mile, the maximum being one hundred and ninety-four feet; its length is a little over seven miles, and its termination is eleven hundred and sixty feet higher than its beginning. The favorite seat in ascending the mountain is in a car in front of the locomotive; on the way back the same individual generally chooses the rear car; and it has been noticed that one experience of this excursion, like that of passing under the fall at Niagara, is generally sufficient. Both of these trips were taken by the delegates, with great satisfaction and enjoyment. A reception by the Blair County Medical Society, with a social supper at the Logan House, completed the entertainments.

This meeting was the thirty-first annual session of the State Society. The meeting began May 19, 1880, and continued three days. The usual reports were received deprecating the low standard of qualifications and the easy terms upon which diplomas are obtainable, and the example of the Harvard Medical School was pointed out as worthy of imitation by other colleges. In the report on Medical Legislation, the traffic in bogus diplomas was severely condemned, and a committee appointed to confer with the representatives of the regular schools upon the best method of relieving this community of a standing disgrace. Speaking of the existence of sects in medicine, such as hydropathic, eclectic, homœopathic, vitopathic, etc., it was declared that twenty chartered institutions devoted to these pathies are in operation in the United States, and most of them are openly engaged in the diploma traffic.

MEDICAL EDUCATION.

Dr. Andrew Nehring, in the president's address, said that education in most medical colleges had made but little real progress for thirty years. He earnestly advocated greater uniformity in the qualifications for the degree, the establishment of an efficient preliminary examination, and the extension of the collegiate course to four years.

HYGIENE.

The committee on hygiene in its report considered particularly the short-comings of the plumber and building contractor, and called for legislative action in order to establish the office of inspector of plumbing and drainage in every town and city provided with a system of sewerage, in order that all house connections, etc., could be regularly examined. A committee was

appointed to memorialize the legislature upon this subject, consisting of Drs. Lee, Dale, and Woodbury.

The number of papers that were offered to be read and the inevitable appearance of some whose quality was inversely as their length again demonstrated the need of the appointment of an examining committee, to whom all papers should be sent in advance of the meeting, so that those of inferior merit should not occupy the time of the session to the exclusion of better ones. We have room here only for a mention of the principal ones.

THE TREATMENT OF ASTHMA.

Dr. William Pepper, of Philadelphia, read a communication entitled *Some Practical Remarks on the Treatment of Asthma*. Asthma he considered as including not only the attacks, but also the peculiar tendency to the paroxysms which exists in the interval between them; in the same manner as epilepsy is constituted not simply by convulsions, but by the nerve lesion or disorder that leads to their recurrence. He believed that the essential factor in asthma is "a condition of morbid susceptibility or of actual disease of the nervous filaments supplying the ramifications of the bronchial tubes, and, perhaps, of the thoracic ganglia of the sympathetic." The principal or most common factor associated with asthmatic attacks is bronchial congestion; but the paroxysms may be induced simply by reflex irritation, from indigestible food, for instance, those showing a resemblance in pathology to spasmodic croup. In the treatment the removal of the underlying morbid condition and the palliating of the actual attacks both demand consideration. Two classes of asthmatics had been noticed particularly, the plethoric and the anæmic. The first are characterized generally by sedentary habits and the use of alcohol; and more or less swelling of the liver, sluggish digestion, and high-colored urine with excess of urates, coexist. The chest walls are apt to be heavily coated with fat, the heart's action is labored, and the skin is very susceptible to sudden changes of temperature, or to draughts and damp. Now if in such subjects a tendency becomes established to bronchial congestion, repeated attacks of asthma will readily occur. Bronchial catarrh gradually becomes a more prominent feature, a varying amount of vesicular emphysema is established, and trifling causes will now invite the attacks. Some of the worst cases belong to this group. The second class are poorly nourished and decidedly anæmic. Asthma is readily instituted in such patients, and indeed the tendency to spasmodic nervous affections not rarely precedes any local bronchial trouble, although bronchial catarrhs are also of frequent occurrence. In these cases phthisis may ensue, but more frequently emphysema (atrophic or hypertrophic) occurs, the heart fails seriously, and the case assumes grave features. Among the principal indications for treatment are: (1) restoration of tone to the skin and the muscles; (2) relief of congestion of the liver and of gastric catarrh; (3) improvement of the power of the heart and of the peripheral circulation; (4) removal of morbid conditions of bronchial mucous membrane, and of the morbid irritability of the nerves supplying the pulmonary tissues; and (5) repairing the vesicular emphysema that has resulted from the asthmatic attacks and the persistent bronchitis.

Gymnastic exercises, baths, frictions, inunctions, and the careful hygienic management of the case are in-

sisted upon as essential to the successful treatment. Changes of climate, especially from a damp to a dry, bracing atmosphere, is recommended as a remedy of primary importance. Where abdominal plethora is marked, the use of mild salines, such as Carlshad or Bedford water, with an occasional blue pill, is needed. Mineral acids, with quinia and strychnia, are often indicated. In anæmic cases a pill of strychnia, digitalis, arsenic, and iron has been used with advantage, after due attention had been paid to the digestion. Where the heart is embarrassed by local congestions, dry cups to the chest twice a week afford great relief. Associated bronchitis (subacute) requires alkalies, iodide of potassium, and perhaps corrosive sublimate in small doses. In cases of copious muco-purulent secretion the use of copaiba and erydriodene are especially valuable. Spasm of bronchial tubes calls for the bromides in small doses, or a hypodermic of morphine and atropia, but the continued use of sedatives is injudicious. The nitrite of amyl is sometimes palliative. Inhalations of carbolic acid and iodine are beneficial, and Waldenburg's apparatus affords the best means of pulmonary gymnastics, especially to be recommended where the vital capacity is below the average. Where the paroxysm is reflex, a mild emetic is sometimes useful; but due attention to the stomach and the secretions is imperative. Asthma cigarettes, consisting mainly of powerful sedatives and nitrate of potassium, frequently yield relief during an attack, but the writer had obtained excellent results from the following combination given internally:—

℞ Ammonii bromidi	5ij-5ij.
Ammonii chloridi	5ss.
Tr. lobelia	15ij.
Spts. ætheris comp.	ʒi.
Syrup. acacia	q. s. ad ʒiv. M.

S. A desert-ponion in water, repeated every hour or two during the severity of the attack.

Dr. J. Solis Cohen exhibited his method of hyperdistention of the air cells by means of an ordinary perfume atomizer bulb. In cases of catarrhal character, where the bronchioles are clogged and there is more or less collapse of air cells, a full inspiration, followed by auto-inflation by this hand-ball through a rubber tube held in the mouth (the patient at the same time holding his nose), is generally followed by forcible expiration and free discharge of bronchial secretions, giving great relief to the patient.

Dr. William Goodell read a paper on the Treatment of Uterine Fibroids by Enucleation.

BROMIDE OF ETHYL.

Dr. John B. Roberts presented a communication upon the use of the bromide of ethyl in practical surgery. Dr. Lewis also held a clinic, at which eleven patients were ethylized with the best results. Dr. Benjamin Lee read a paper on the alkaloïds of cinchona, in which he recommended a mixture of the cheaper alkaloïds with fifteen per cent. of quinia, in a preparation known as quin-quina. Dr. S. M. Ross, of Altoona, exhibited a case of double amputation at the knee-joints after railroad crush; the remarkable feature in the case consisting in the fact that the operation had been performed with only the instruments contained in a small pocket case.

The oil of ergot and oleic iodoform (oleic acid ʒi., iodoform gr. xxiv.) were recommended as applications in skin diseases by Dr. John V. Shoemaker

Professor Pancoast spoke of the formation of a new joint after excision; and also of the importance of moderate, not extreme, extension and rest in the treatment of joint disease. He also advocated puncture of the capsule when it is distended in the stage of effusion. Dr. Hewson reported cases of synovitis of the knee and of ovarian tumor cured by clay dressing.

Dr. Coover, of Harrisburg, showed the silicate-of-soda apparatus for spinal deformity, which is lighter and more durable than plasters.

The leather jacket was recommended by Dr. Charles T. Hunter during convalescence and for beginning lateral curvature.

Reports on progress in obstetrics, by Dr. J. T. Carpenter, of Schuylkill County; in surgery, by Dr. John H. Packard, of Philadelphia; in mental disorders, by Isaac N. Kerlin, of Media; in medicine, by Dr. Thomas Shaw, of Allegheny; and in hygiene, by Dr. Benjamin Lee, were also on the programme.

PROCEEDINGS OF THE CONNECTICUT RIVER VALLEY MEDICAL ASSOCIATION.

THE annual meeting was held at Towns' Hotel, Belows Falls, Vt., May 5, 1880. Thirty members were present; DR. A. P. RICHARDSON, president, in the chair.

DR. PORTER read a paper on Diseases of the Respiratory Organs. The treatment of thirty or forty years ago, with venesection, antimony, and mercury, was compared with that of the present time, by quinine, stimulants, and wet applications. It was shown that the mortality is much less now than under the old treatment.

In the discussion which followed, DR. WEBSTER remarked that he had met with a case of pneumonia where the temperature was $108\frac{3}{4}^{\circ}$ F., the patient living only three or four days afterwards. DR. GRAY had seen a case of typhoid fever with a temperature of $107\frac{1}{4}^{\circ}$ F., recovery following. The patient took sixty grains of quinine at one dose.

FOREIGN BODY IN THE LUNGS.

DR. SPOFFORD reported the case of a young man who drew a head of herd's grass into his lungs August 3d. Not much trouble ensued until August 21st, when he had a chill, with pain and dullness over the lower part of right lung. September 14th, abscess of lung broke and discharged, producing considerable strangling. Bits of the herd's-grass head appeared in the sputa. November 25th, he had an attack of hæmoptysis; December 3d, another; and March 5th he raised a head of herd's-grass two and one fourth inches long, which was shown the members. A good recovery followed.

DR. D. CAMPBELL reported a similar case, where a pint of offensive pus was discharged from the abscess.

SUBMUCOUS FIBROID TUMOR OF UTERUS.

DR. BRYANT related case of a woman who had a chill a few days after her third confinement, followed by a temperature of $107\frac{1}{2}^{\circ}$ F. Cleansing uterine injections were used. A state of septic irritation existed for several days. In three weeks the introduction of a tube into the uterus was found to be difficult, and a

uterine fibroid tumor the size of a hen's egg was discovered. This had acted as a valve, preventing a free discharge of the lochia, and was the controlling factor in producing the septicæmia. It was removed, with the use of speculum, by twisting, the pedicle being two fingers in breadth. Four days afterwards a severe hæmorrhage ensued. Patient recovered.

Recent Literature.

On the History and Statistics of Partial and Complete Resections of the Scapula. By GEORG F. B. ADELMANN. Professor of Surgery at Dorpat.¹

In an exhaustive critical and historical analysis of 195 cases of partial excision and of 66 complete extirpations of the scapula, Professor Adelmänn groups these operations according to the date, and the ages, sex, and nationalities of the patients, and the causes, whether traumatic or pathological. Of the 195 partial excisions of the scapula, 153 were for injuries, 41 for diseases, and 1 for unknown cause, with a mortality of 26.3 per cent. for the determined cases of resection for injury, and of 19.5 per cent. for the resections for disease. Of the 66 complete excisions of the scapula, 22 were for injury, 43 for disease, and 1 for unknown lesion, with a mortality of 27.2 per cent. for the traumatic and 19 per cent. for the pathological cases. Of the 261 excisions of the scapula — 66 total and 195 partial — the sex was recorded in 252: the males presented 223, with 176 partial and 47 complete resections; and the females 29, with 15 partial and 14 complete excisions.

In his extended bibliographical references, Professor Adelmänn cites F. Ried, O. Heyfelder, G. B. Günther, Stephen Rogers, H. Culbertson, and the Surgical History of the War of the Rebellion, 1861-65. From the last treatise he quotes quite freely, introducing his citations in the following terms: —

"This compilation by Otis classifies the injuries that came under observation during the North American war, from 1861 to 1865, and constitutes a work the like of which the European continent does not possess, presenting a splendid example, in a surgical point of view, for future compilations of results obtained in our recent European wars. The cases which are of interest for the operation under consideration, partly form a distinct class in this collection, and partly are scattered among the traumatic lesions of the bones making up the shoulder-joint. They form a prominent contingent of our table of partial resections of the scapula, and are of great value for war surgery. The arrangement in Otis's work is readily understood. While the text contains reports of wounds and operations of the war of the rebellion, extensive annotations at the end of each chapter testify to a comprehensive acquaintance with entire surgical literature; so that, although the cases detailed by Dr. Otis indicate only a more or less partial removal of the shoulder-blade, extensive references to a series of partial as well as total scapular operations are found in the annotations. Continuing Dr. Rogers's tables, Dr. Otis adds the more recent operations. Among them

¹ Zur Geschichte und Statistik der theilweisen und vollständigen Schulterblattresektionen. Von Dr. Georg F. B. Adelmänn, Professor Chirurgie emer. Dorpatens. Separatabdruck aus der Vierteljahrsschrift für praktische Heilkunde, Bd. cxlvii., 1879.

I have found — besides such as have been published by other writers — reports of several cases which I have been unable to verify, and which, of course, I could not take up on my tables. For instance, Otis cites a case of Professor Pirrie, which, however, in details, exactly agrees with Syme's case in 1856, and quotes as authority the *Principles and Practice of Surgery*, third edition, 1873, page 812; a work that I was unable to obtain. Under No. 5 is given a case published in the *Dublin Press*, November 13, 1861, without name of operator, in which the removal of the shoulder-blade, by reason from necrosis, on a patient named Messick, resulted in recovery with useful arm. Farther, Otis calls attention to a case of Dr. Twitchell, of Keene, New Hampshire, in 1838, in which the scapula, clavicle, and arm are said to have been removed. The patient died after several months of relapse. (*New York Medical Journal*, 1869, vol. viii., p. 434.) In the same report, a case of Dr. Krakowitzer, New York, 1868, is said to be described, in which the scapula was removed by reason of chondroma, five years after amputation of the arm, the patient succumbing from exhaustion seven days after the operation. The *Dublin Press*, as well as the *New York Medical Journal*, have, in spite of many efforts, proved inaccessible to me. Furthermore, it is stated in Otis's vol. ii., p. 498, note 2, that Surgeon H. L. Thomas, of Richmond, reported a case of the Confederate army, in which Surgeon B. G. Dysart resected, on June 30th, the entire scapula and the head of the humerus of a corporal who was wounded in the left shoulder on June 27, 1864. Further details are wanting."

Dr. G. A. Peters, in his history of a case of excision of the entire scapula for cancerous disease, in the *American Journal of Medical Sciences* for July, 1878, vol. lxxvii., p. 103, remarks that since the paper by Dr. Stephen Rogers the records of resections of the scapula have not been tabulated. The student will find, in the careful tabulations of Professor Adelnmann, the subject brought up to date.

A Text-Book of Physiology. By M. FOSTER, M. A., M. D., F. R. S. From the third and revised English edition. By EDWARD T. REICHERT, M. D. Philadelphia: Henry C. Lea's Son & Co. 1880.

The apology which this reprint offers for its existence is that it has been "adapted to the wants of the American student." This adaptation consists in the insertion of a mass of anatomical data, which seem to us eminently unnecessary, and which detract from the symmetry and perfection of the original work. Why, with all the anatomical and histological books at their command, American students should require to be fed on pap especially masticated for them, or why they should be so much inferior to their English cousins in the knowledge of such elementary anatomical facts as are intercalated into this edition, we fail to perceive. It is extremely exasperating, in the midst of a brilliant discussion of the functions of an organ or of its secretions, suddenly to find one's self wading into a waste of dry anatomical data, which are as much out of place in such an association, as a lot of foot-notes regarding color and perspective would be on the face of a beautiful painting. An artist assumes that his inspectors know enough about such matters to enjoy and profit

by his work, while those who desire more ample instruction in regard to detail can seek it in appropriate books and charts. Guided by a truly artistic instinct, Foster wisely limited himself to his subject, — pure physiology, — and confined his anatomical references to such facts as are actually involved in the interpretation of function.

The only point wherein this edition can justly claim commendation lies in the fact that the American editor had the good sense not to offend by attempted emendations of the original text. We prophesy for this book a justly merited brief career, because students will inevitably seek the original and unadulterated article when they realize that anatomy can never be properly studied from foot-notes, and that the pleasure of a physiological demonstration is only marred by the intrusion of extraneous and superfluous matters.

G. M. G.

A Hand-Book of Hygiene and Sanitary Science. By GEORGE WILSON, M. A., M. D., etc., etc. Fourth edition enlarged and carefully revised. Philadelphia: Lindsay and Blakiston. 1880.

The previous editions of this book have made it known as a very excellent one. In order to keep it up to date much new matter has been interpolated throughout, but the page has been somewhat enlarged, so that the size of the volume has not been materially increased. A new introductory chapter, giving a brief historical sketch of the progress of sanitary science and of recent sanitary legislation, has been substituted for the introductory chapter which appeared in previous editions. The author, who is the medical officer of health for the Mid-Warwickshire Sanitary District, embraces the belief in the *de novo* origin of enteric fever, and states that, whether the disease is produced by befouled air or polluted water, there is a constantly accumulating amount of evidence which goes to prove that neither the air nor the water need be tainted with the specific contagium of the disease; he does not, however, explain why it is that such vast amounts of befouled air and polluted water are constantly consumed without giving rise to typhoid fever. He again says: "In villages and country districts an epidemic of typhoid fever points to polluted wells, bad drainage, or filthy privies, all of which may originate the disease in the first instance, as well as be the means of propagating the specific contagium when it is developed or introduced. It cannot be said that he is wrong, but the present state of knowledge on this subject hardly justifies such positive statements.

The book as a whole can be warmly recommended.

—The Medical Association of Central New York held its thirteenth annual meeting at Rochester on the 18th of last month. The occasion seems to have been an agreeable one. Various papers were read. The address of the president, Dr. Hyde, touched upon medical progress. The committee on prizes offered twenty-five dollars for the best essay on Needed Legal Reforms regulating the Study of Medicine; also a prize of twenty-five dollars for the best paper on a subject to be chosen by the writer.

—Dr. A. Fred Swaine Taylor, the well-known toxicologist and writer on medical jurisprudence, is dead.

Medical and Surgical Journal.

THURSDAY, JUNE 3, 1880.

A Journal of Medicine, Surgery, and Allied Sciences, published weekly by HOUGHTON, MIFFLIN AND COMPANY, Boston. Price, 15 cents a number: \$5.00 a year, including postage.

All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.

Remittances by mail should be sent by money-order, draft, or registered letter to HOUGHTON, MIFFLIN AND COMPANY, Boston, Mass.

THE MEETING IN NEW YORK.

JUDGING from the accounts we have thus far received, the meeting of the American Medical Association promises to be one of the most largely attended and pleasant gatherings which have occurred since its foundation. Early estimates have placed the number of visitors at considerably over one thousand, and certainly nothing could be more satisfactory than the preparation made by the committee of arrangements for their entertainment. The good effects of the present improved organization are beginning to make themselves manifest in the disappearance of unprofitable discussions on ethical or parliamentary questions, and a more strict attention to the legitimate objects of the Association. The list of communications, which we have already given, is a very creditable one. We cannot help feeling, however, that this would improve from year to year were some more desirable method of publication devised than that now existing. Under the present arrangement no one of the members now in New York will be able to judge fairly the work accomplished until after the close of the present year. The greater facilities which our medical periodicals give for the prompt appearance of articles should be recognized by the Association, and we have little doubt that were the rule which retains all articles for the ponderous volume of Transactions exclusively abolished, a much greater inducement would be held out to the best men in the country to bring the results of their labors to the annual meetings. Events follow one another so rapidly nowadays that original work is liable to become stale if it be subjected to a long period of incubation before it sees the light. Few men who have been subjected to the annoyance of long delays in the appearance of Transactions or of comprehensive works by numerous authors will be inclined to repeat their experience. That the present system will not continue much longer in existence is evident from the tone of the president's address. The number of societies devoted to specialties which are springing into existence every year, and take advantage of this great gathering of the profession, is becoming one of the new features of the day. Monday last, the day before the opening of the meeting, was as busy a day of the week, probably, as any of those which succeeded it. The Association of Medical Colleges held its meeting on that day, as did also the Laryngological Society; and a meeting was called for the formation of a new national surgical society. These are to be counted among the good influences exerted by the parent association. Such a powerful

and influential body can easily afford to encourage special work of this kind, which will enable it to devote its energies to questions of a more general bearing upon the welfare of the country and of medical science than it has hitherto attempted. The address of Dr. Sayre, the president, which we give below is a patriotic tribute to American medicine, and contains many interesting suggestions to the members. It is evident that he sees the importance of a departure from the present custom of multiple periodicals, which is so great a hindrance to the progress of medical literature. While we are not prepared to indorse his method of overcoming this evil, arguing from the society's point of view, we feel quite sure that our best journals would not look upon it as in any way prejudicial to their interests.

Miscellany.

THE AMERICAN MEDICAL ASSOCIATION.

ADDRESS BY THE PRESIDENT, PROFESSOR L. A. SAYRE.

GENTLEMEN OF THE AMERICAN MEDICAL ASSOCIATION. — Before entering upon the duties of the high office to which you have elected me, I wish to return you my sincere thanks for the distinguished honor thus conferred, and to pledge you that I will endeavor to discharge its duties to the best of my ability.

No one can feel more keenly than I do my own incapacity properly to fill the distinguished position to which you have elected me, or more sincerely regret that some other, more competent and more worthy of the honor, had not been elected in my place. But as your too partial friendship has thus elevated me to this post, I must appeal to your generosity to overlook any of my short-comings, and rely upon your mutual aid to assist me in the discharge of the important duties thus imposed.

Who can properly appreciate the value of this Association, or the immense advantage it has already been to the medical profession throughout our whole country?

Contemplate for a moment the difference in the *morale*, the devotion to scientific investigation, the mutual respect and good feeling between its members at the present time and its condition when this Association was organized. At that time there were often envyings, jealousies and heart-burnings, fault-finding and detraction. Now each one seems so engaged in endeavoring to improve himself and elevate his own position in the profession that he has no time to devote to studying his neighbor's faults, much less accurately to scrutinize and publicly herald his seeming defects.

The science of medicine has been so much enlarged in all its different departments by the minute researches now demanded, and by the great advance and rapid progress of many of its specialties, as to require that every moment of a man's time be occupied in the closest study if he would keep himself abreast with the daily improvements in our profession. And he who is thus occupied has no time to study the defects of others. By this constant study to improve ourselves and advance our science, the whole profes-

sion becomes more elevated in tone; and we already see that it is becoming more and more respected by the community at large.

Let us contemplate for a few moments what has been done by the profession in America for the improvement of medical and surgical science and the relief of suffering humanity. Many years ago, Sydney Smith, one of England's most popular authors, said, in the *Edinburgh Review*, "The Americans are a brave, industrious, and acute people, but they have hitherto made no approaches to the heroic, either in their morality or their character. During the thirty or forty years of their independence they have done absolutely nothing for the sciences, for the arts, for literature, or even for the statesman-like studies of politics and political economy. . . . In the four quarters of the globe, who reads an American book, or goes to an American play, or looks upon an American picture or statue? What does the world yet owe to American physicians or surgeons? What new substances have their chemists discovered, or what old ones have they analyzed? What new constellations have been discovered by the telescopes of Americans? What have they done in mathematics? Who drinks out of American glasses, or eats out of American plates, or wears American coats or gowns, or sleeps in American blankets?"

It would seem to me that the very Declaration of Independence, and the willingness of the signers to sacrifice life to obtain it, was an act of heroism equal to any recorded in history. And the organization of the government under constitutional law, which has yielded such results as were never before attained, is an evidence of statesmanship and of knowledge in political economy which has been seldom equaled and never surpassed. As to the question of American manufactures and the nations that use them, we can safely refer to the reports of our chamber of commerce for a satisfactory answer. American science has no need to be ashamed of its Henry and its Morse, its Bache, Peirce, Newcomb, Draper, Dana, Marsh, Gray, Hall, and its adopted Agassiz. Nor has the *American Journal of Science* anything to fear by comparison with its European contemporaries. But to the question, "What does the world yet owe to American physicians and surgeons?" we would venture a more full reply, although time will not permit us to revert to more than a few of our professional achievements.

First among the greatest boons ever conferred upon suffering humanity stands "anæsthesia," an American suggestion, and one that immortalizes the name of Morton. Who can ever estimate the value of this discovery, or who can accurately describe the contrast between the former agony necessarily endured in many surgical operations and the present absolute oblivion of all pain,—the happy, tranquil, undisturbed sleep while the flesh quivers under the knife? When we contemplate the millions of human beings on the earth, and consider the fact that at every moment of time, in some part of the civilized world, hundreds, if not thousands, are receiving the benefits of this great discovery, the mind becomes overawed at the magnitude of the blessing, and even imagination fails to comprehend fully its benefits.

Ovariectomy, another American contribution to the medical profession, has done probably as much toward saving life as any other surgical discovery in the nineteenth century. It was first practiced in 1809, on

Mrs. Crawford, in Danville, Ky., by Dr. Ephraim McDowell. Although honestly and modestly reported, eight years afterward, in the Philadelphia *Eclectic Repertory and Analytical Review*, it still made no impression on the professional mind, but was received rather with derision and scorn, until Dr. Atlee, in 1844, revived the operation, and by persevering effort, in spite of all opposition and the very general condemnation of his contemporaries, was enabled at last by his numerous brilliant successes to establish the operation on a permanent basis. At the present time it is acknowledged as the proper operation to perform, in certain cases, by every medical school in the civilized world. Dr. Peaslee says that "in the United States and Great Britain alone ovariectomy has, within the last thirty years, directly contributed more than thirty thousand years of active life to woman, all of which would have been lost had ovariectomy never been performed."

In gynecology, the whole professional world cheerfully and gratefully acknowledges the original and invaluable contributions of Sims, Thomas, Emmet, Peaslee, Atlee, Kimball, Dunlap, Minor, and others in this department.

The new operation of litholapaxy, which consists in the entire fragmentation of calculous material in the bladder, and the prompt and entire removal of the debris by aspiration through a tube passed by the urethra at a single sitting, first performed and described by Dr. Bigelow, of Boston, is one of the grandest triumphs of modern surgery, one of which any American surgeon may feel justly proud.

In conservative surgery, we certainly compare favorably with any other nation. The mechanical treatment of diseases of the joints, by which means the patients are able to take free exercise in the open air during the whole progress of the disease, thus acquiring power to overcome the constitutional dyscrasia better than by any means heretofore employed; and, when the disease has progressed beyond repair, the sub-periosteal excision of the joint in such a manner as to leave the muscular attachments in their normal position, and by judicious after-treatment to restore them with but slight deformity and almost perfect power of motion,—these certainly are triumphs in surgery of which the American profession may well be proud.

In the *Lancet* of February 14, 1880, Mr. Roderick MacLaren, M. D., surgeon to the Cumberland Infirmary, in his presidential address to one of the branches of the British Medical Association, on The Advances in Surgery during the Past Twenty Years, says, "No account of the recent progress in surgery can justly omit the application of the principle of absolute rest to diseases of the vertebrae. It is done by inclosing the body in a plaster-of-Paris jacket. Though only introduced into this country about two years ago, it has established itself as an *incontrovertible success*." This is another triumph for American surgery, and is justly admitted not only in England, but in all parts of the civilized world.

When we contemplate the misery and suffering of the unfortunate "hump-back," who, after years of torturing treatment, has for its termination only deformity or death, or the patient with a bad lateral curvature, who, in addition to the deformity, has for years suffered constant agony from the application of the cruel instrument of torture, intended for his relief, but

never successful, and compare his condition with that resulting from the present mode of treatment, which is void of all danger, perfectly painless in its application, allowing the freest exercise and enjoyment during its progress, always affording immediate relief even in cases that have passed beyond the hope of cure, and in the majority of cases, when the treatment has been commenced at a proper time and judiciously carried out, terminating in a perfect result. — frequently leaving no trace of deformity as an evidence of its previous existence. — we feel that American surgery has a right to congratulate herself that she has contributed this great boon for the relief of human suffering.

In laryngology, we can certainly claim Green as a pioneer, and we all know the censure he received and the opposition he encountered; but the facts he then established are now acknowledged by the entire scientific world, and the improvements made in this department of surgery by Cohen, Cutter, Bosworth, Elsbury, Lincoln, Lefertis, Robinson, and many others in this country, entitle us to rank with other nations.

Time will not permit us to refer to all of our contributions in the different departments of medical and surgical science, but I have enumerated enough to justify the belief that if the distinguished author before referred to were now to write he would express very different sentiments from those above quoted. Not content, however, with what we have already achieved, let us still press onward, and, accepting the motto of our great State, constantly cry "Excelsior."

METRIC SYSTEM.

It is the duty of this Association carefully to investigate every claim to improvement or advance in medical and surgical science; and, if such claim is found to be worthy of confidence, to lend such innovation or improvement the moral influence of its support. One of these innovations is the substitution of the "metric system of weights and measures" for our present uncertain "formula."

At the meeting of this Association in Buffalo, June 5, 1878, the following resolution was passed by the section of Practical Medicine, Materia Medica, and Physiology: Resolved, "That this section, recognizing the value of the metric system for its uniform, international, indestructible, generally applicable, convenient, simple, safe, and scientific character, hereby recommends to all physicians the use of the same in their practice, and in their writings and teachings."

The present objectionable methods of dispensing medicine have the great advantage of prestige. To overthrow this and to secure for the metric system the mere opportunity to become generally known will require persistent effort on the part of its friends, aside from such concert of action as may be implied in the passage of resolutions. At the outset it may be observed that physicians are not put to the necessity of learning the entire terminology of the metric system, simple as this may be. The only unit of volume to be remembered is the *cubic centimetre*, occupying the space of a gaming die, or of a cube whose edge is about four tenths of an inch. The only unit of weight is the *gram*, which is the weight of one cubic centimetre of pure water at its heaviest. Its English equivalent is a little over fifteen grains.

No one objects to either the name or the use of dollars and cents, and no one on this side of the Atlantic

would be willing to give up our decimal mode of counting money for that of pounds, shillings, pence, and farthings, in which reduction from one denomination to another is a perpetual source of annoyance. By the simple change in position of a decimal point, we are able, without the change of a single figure, to express the fortune of a millionaire in fractions of a cent.

The reasoning which has been applied to the dollar in contrast to the British pound sterling is equally applicable to the gram in contrast with the British ounce *avoirdupois* or ounce *apothecaries*. A pound *avoirdupois* is made up of sixteen ounces, each of which weighs four hundred and thirty-seven and a half grains, making seven thousand grains in all. A pound *apothecaries* is made up of twelve ounces, each of which weighs four hundred and eighty grains, making five thousand seven hundred and sixty grains in all. The confusion resulting from this inconsistent use of the same name for things of different value is interminable and unnecessary. Let the use of the pound and ounce be replaced by that of the *gram*, which is perfectly definite in value.

Tables of equivalent have been in use for two years past in the United States Marine Hospital Service, at Washington, where the employment of the metric system was made obligatory in the spring of 1878, by order of the surgeon-general. To this department application was made, a few weeks since, for information as to the success of the experiment, the object had in view being to place before this Association actual results rather than theoretic arguments. To the surgeon-general, Dr. John B. Hamilton, the following questions were put: —

- (1.) Was any serious difficulty encountered by dispensing clerks in laying aside the old system and substituting the new?
- (2.) Have mistakes in dispensing occurred with any noticeable degree of frequency in consequence of lack of skill in the management of decimal points?
- (3.) Has any serious loss of time or of accuracy resulted from the substitution of gravimetric for volumetric methods of dispensing liquid medicines?
- (4.) In case volumetric methods have been retained, have mistakes or difficulties arisen from the necessity of carrying in mind the specific gravities of the liquids measured, and allowing therefor?
- (5.) Is there any apparent disposition on the part of dispensing clerks or nurses to return to the old system?
- (6.) Have you any suggestions to offer, based on the practical trial already given in the United States Marine Hospital, whereby the adoption of the metric system by members of the American Medical Association, and by druggists in the country at large, may be facilitated?

The reply of the surgeon-general is so pointed, clear, and satisfactory that no better service can be done in the cause of metric reform than by incorporating it, as a whole, in this address: —

DEAR SIR, — Referring to your letter of the 3d inst., I have to say in answer to the questions submitted: —

- (1.) No serious difficulty has attended the adoption and exclusive use of the French decimal metric system in this service.
- (2.) No mistakes have occurred on account of the change, so far as known to this office.
- (3 and 4.) Volumetric methods were retained, and as liquids have always been measured in the dispensing of medicines in this country less inconvenience and trouble must necessarily attend the adoption of the metric system referred to if measures be retained than if gravimetric methods be exclusively employed, since the latter course would render it necessary to carry in mind the specific gravities of many liquids, and to make allowances accordingly in converting the terms of the old system into those of the new.
- (5.) The discipline in the marine hospital service would prevent any opposition on the part of dispensing clerks or nurses.

(6.) The suggestions I would make, based upon the experience in this service, are the following:—

In order to facilitate the general adoption of the new metric system in medicine and pharmacy, volumetric methods should be retained. On the one hand, this would save much labor which would otherwise have to be done by prescription writers; and, on the other hand, it is fair to presume that whether liquids be prescribed in grams or in cubic centimeters they will be dispensed quite generally by measure. The principal merit of the new system lies in the fact that with nearly all liquids except syrups, glycerine, chloroform, and ether the grain and the cubic centimeter will represent the same quantity practically.

The terms used to designate the units of the metric system should be anglicized as far as practicable, and the units reduced to the smallest number requisite. Prominence should be given to the "gram" and the "cubic centimeter," as being the only units with which it is necessary to be familiar. After the gram, the *centigram* is the unit most applicable in medical and pharmaceutical gravimetry, and multiples and subdivisions of these two weight units are sufficient, in my opinion. All the other prefixes used in the French system should be avoided in adopting that system for physicians and pharmacists, the "centi" alone being retained. The cubic centimeter seems to me to be a more suitable unit for use in medical formulae than any subdivision of the liter.

In conclusion, it would be well if all friends of the metric system could agree to drop the fractions in the numbers which express the equivalents of the gram and the cubic centimeter in troy grains and minims, and to adopt the exceedingly simple rules for converting terms of the old system into those of the new, and *vice versa*, that have been found so useful in the practical trial given the decimal metric system in the marine hospital service, the medical officers of which are now prescribing in metric terms for over twenty thousand patients annually. These rules were adopted simply as an aid in learning metric posology, and their usefulness ceases as soon as the pre-crisis is familiar with the expressions in metric terms of the doses of medicines, and they are probably not now used to any extent by the officers of this service. I am, sir, very respectfully,

JOHN B. HAMILTON,
Surgeon-General M. H. S.

PUBLICATION OF TRANSACTIONS.

For many years past there has been an almost annual complaint about the publishing of our transactions. Sometimes it would be that publication had cost altogether too much money; at other times that they were not issued with sufficient promptness, and the volume when received was almost useless, since all the important papers or discussions in it had already appeared months before in the various medical journals of the country.

Upon considering carefully these objections, which have been increasing every year, it would really appear as if there were some just ground of complaint. And, since the matter is of very grave importance, I would respectfully suggest that the Association give it very serious consideration, and, if deemed advisable, refer the subject to some proper committee, to report whether any plan can be suggested to bring the proceedings of the Association before the profession that would be better than the one now pursued. Certainly our present plan, besides being very expensive, does not give entire satisfaction; and it is very questionable whether the model pursued by the British Medical Association, in establishing their own journal, would not be an immense improvement on our present method.

The *British Journal* is the exclusive property of the association; and by the liberal compensation of an accomplished editor a weekly edition is issued instead of an annual volume. Certainly this plan implies great economy; for, instead of being an expensive burden, as at present, the work of publication would, in a very short time, be a source of direct emolument.

Any one who has attended the meetings of the British Medical Association, and who is acquainted with

its journal for the last ten years, may have observed that the extraordinary growth of that association in power, wealth, influence in the profession, and influence in the state has been coincident with the development of a weekly organ of communication between the members, the property of the association, the journal of the association, and edited by a member of the profession, appointed for the purpose by the council of the association. This history, as told by these gentlemen, and as any one can confirm for himself by examining the facts, is extremely instructive in establishing at least one solid base for prosperity for any similar institution, such as the American Medical Association. Briefly to summarize the facts, it may be stated that the British Medical Association was founded forty-six years ago by Sir Charles Hastings, a country physician, mainly for the purpose of advancing the professional interests of country physicians. Its growth was rapid, and in time it became British rather than provincial. The greatest men in England became annual presidents; its meetings were held in London, Edinburgh, and Oxford, and as a body it was highly respected. It soon appeared, however, that there was a comparatively narrow limit to its powers of extension. At each meeting considerable accessions of new members joined, but they soon fell off again. Then it was found necessary to convert the annual volume of transactions into a weekly journal. It was noted that the provincial transactions, admirable as they were, formed a volume which did not appear for some months after the annual meeting; that such a volume was put upon the shelves, and occasionally referred to, but rarely read through; that it did not appear until the interest of the meeting had faded away, and until a good deal of the freshness had been taken off the papers by short abstracts and piecemeal reports; and that on the whole it was impossible to expect the association to spread unless means were provided for more constant intercommunication between the members, and for the more rapid publication of their contributions to medical science and the more continuous discussion between the members of subjects of medical, social, and ethical interest in the intervals between the meetings.

The publication of this journal had at once a favorable influence on the fortunes of the society. The members grew from one thousand to two thousand, and the society continued to make slow and steady progress, adding definitively about thirty new members a year to its total numbers. Twelve years ago, however, upon the resignation of Dr. Markham, a new editor was appointed, Mr. Ernest Hart, who was at that time coeditor of the *Lancet*, accepting the office of editor of the *British Medical Journal* on condition that he was allowed considerably to increase the size of the *Journal* and to conduct it in a thoroughly energetic and independent manner, in such a way as to make it worthy of being the weekly organ of a powerful association. Under his direction the *Journal* was at once doubled in size. It was brought into a state of scientific and social activity, and made an organ of the most recent scientific and professional work, and its editorial departments were conducted with vigor and literary skill.

The effect upon the fortunes of the association was magical. Five hundred new members joined that year, and for each successive year since that time, from five hundred to six hundred new members have

been added to the list by the simple process of sending throughout the country, once or twice in the year, copies of the *Journal*, and forms of application for membership. The result has been that whereas for the thirty-six years that the association had existed it had only slowly crept up to about two thousand, it has, during the ten years that Mr. Ernest Hart has edited the *Journal*, risen in numbers until it now includes eight thousand members of the profession, and, according to the statements printed in the *Journal*, it circulates another fifteen hundred copies outside the profession. It gives forty pages of printed matter every week, so that the *Lancet* has felt itself called upon to enlarge the number of its pages in order to bring them up to its now formidable rival; but the *Journal*, by reason of the closeness of its type, still gives about one fourth more matter than its senior rival. The circulation of the *Journal* is now alleged to be some thousands more than that of the *Lancet*, and larger than that of any other medical paper in the world. Certainly the British Medical Association has in this way become the most powerful medical association in the world. The way in which the *Journal* has done this has been by converting all its subscribers into members of the association, by a very simple process. Branches have been formed not only all over England, but throughout Scotland and Ireland; and new branches are being formed of members of the association who have emigrated to Australia and India, and still desire, by the branch organization of the association, to maintain close relationship with the profession in the mother country.

The total income of the British Medical Association is about seventy thousand dollars, of which twenty-five thousand are from advertisements in the paper, and the balance from subscriptions of members and sales of the *Journal*. Out of this income are defrayed the salary of the secretary, — not a medical man, but a business man, — who acts as business manager of the *Journal* and general business secretary of the association, at a salary of twenty-five hundred dollars a year, giving his whole time to the work; also the rent of a building, centrally situated, which serves as the printing and publishing office for the *Journal*, and also a gathering place for the committees of the association throughout the year.

There are, further, defrayed the expenses of the various standing committees appointed for special purposes, such as, last year, "the promotion of legislation for habitual drunkards;" the standing committee for the examination of bills brought into Parliament affecting medical interests, and for the promotion of clauses beneficial to medical interests, or the opposing of provisions considered likely to be injurious to them; and other similar committees. There is a further payment out of funds of the association for the promotion of researches in medicine and the collateral sciences. A thousand dollars were voted in this way to Professor Hughes Bennett and Professor Rutherford, of Edinburgh, for the expenses of their famous researches on Calomel and other Agents having a Reputation as promoting a Flow of Bile. In all, about fifteen hundred or two thousand dollars a year are voted in this way. Certain contributions are made towards expenses of the annual meeting, especially the printing expenditure, and from time to time special grants are made towards specially important medical objects. The editor of the *Journal* is paid about five thousand dollars a

year, including payments for his editorial writing, and the sub-editors about twenty-five hundred each.

The literary expenses for payments to writers on the staff for editorial articles, reviews, criticisms, and the like amount to about another five thousand dollars a year. After all expenses are paid, there remains now an annual surplus of from three thousand to five thousand dollars, which has been accumulated into a reserve fund. If, then, we review the position of this powerful association, we shall see that it has a formation which includes, first of all, a strong central executive; this is elective, mainly from its twenty-eight branches, each of which sends one delegate to the central council, generally the honorary secretary of the branch. This central council includes all past presidents and twenty members elected at the annual meeting; and it meets once a quarter at least, or more often under special emergency.

The central council is a powerful executive institution. It delegates the business conduct of the *Journal* to a Journal and Finance Committee, which meets also once a quarter, occupies itself chiefly with passing accounts and general questions of finance and business management, and communicates with the editor upon any subjects which may have arisen during the quarter. There are also a considerable number of standing committees, appointed at the annual meeting to consider special subjects, whose powers are strictly limited by the terms of reference, but who work throughout the year, and who derive their funds solely from special grants by the central executive committee. The standing Committee on Parliamentary Bills consists, like the executive council itself, of a representative of every branch and ten members appointed by the annual meeting, and is a most powerful protector of all medical interests. With this organization, the association possesses in the weekly *Journal* the means of keeping all its members in constant communication one with another. The addresses given at the annual meeting by appointed orators in each subject are at once printed in full in the *Journal*. Every paper read is printed in abstract, together with a report of the discussion excited by it. Thus the association secures for itself a full, rapid, and responsible report, which comes at once into the hands of all its members and of all those in the profession.

These details are of importance to the American Medical Association, for they include the germs of an organization peculiarly adapted to American ideas. It is essentially democratic and entirely representative. It is dependent for its success on the intelligence, union, and good-will of the members. It is decentralizing, inasmuch as it tends to the formation or the strengthening everywhere of the local societies, which have thus throughout the year the means of making themselves heard in metropolitan centres, and of communicating with each other. Above all, it is a most successful and influential means of increasing the membership, enlarging the power, and widening the basis of the association, and of making it a living organism during the intervals between the annual meetings. Finally, it has the great advantage of securing the largest amount of value to each and all of the members for the smallest possible subscription. The *Journal* becomes, in fact, a coöperative enterprise, in which the profits resulting from their subscriptions go into their own pockets.

One point, however, that is specially worthy of note

is that the success of the *British Medical Journal* has been largely dependent upon the manner in which it has been conducted. It will be necessary to find for any organ which this Association may publish an editor of recognized position, whom the Association would accept as its worthy officer and representative in so responsible a post. The question is one which appears to be well worthy of thorough examination by the council and members of this Association, because it seems tolerably certain that if for the present bulky, tardy, little-read, and unproductive volume of transactions there could be substituted an active, vigorous weekly journal, read everywhere, and with a large income, such as would naturally come to it from its advertising sheet, there would be in such a change the earnest of a rapid and important growth in the numbers, influence, and usefulness of the American Medical Association.

ANNUAL MEETING OF THE AMERICAN MEDICAL ASSOCIATION.

As had been anticipated, the thirty-first annual meeting of the American Medical Association was very largely attended, and was one of the most successful and satisfactory sessions of this body which has yet been held. The city of New York, owing to the convenience of access and its numerous attractions, offered unusual inducements for the meetings, which were held in the lecture rooms of the College of Physicians and Surgeons, and in the Young Men's Christian Association rooms, on the southwest corner of Twenty-Third Street and Fourth Avenue, opposite to the college. The course of the proceedings was marked by harmony and dignity; much credit is due to the committee of arrangements for the admirable manner in which the business and entertainments were provided for. The number of papers that were presented was so great, no less than one hundred and eighty-four having been placed in the hands of the committee, that it was utterly impossible to have them all read at the meeting. This pointedly illustrates the truth of the opinion, held by more than one member of this body, that all papers should be sent to a special committee in each section at least thirty days in advance of the meeting, so that it can be determined whether such papers are worthy of being read. It is growing more evident every year that the time of the members of this Association is too valuable to be spent in listening to some inferior production which has already, perchance, been refused by the medical journals.

It seems invidious to name only a few of the distinguished men who were present, but in addition to the officers of the meeting, — Prof. Lewis A. Sayre, of New York; Vice-Presidents R. Beverly Cole of San Francisco, H. O. Marcy of Massachusetts, F. Peyre Porcher of South Carolina; Secretary William B. Atkinson, of Philadelphia; Treasurer Richard J. Dunglison, of Philadelphia; Assistant Secretary Walter R. Gillette, of New York, — we observed upon the platform Professors H. I. Bowditch of Boston, S. D. Gross, H. Pancoast, and Roberts Bartholow of Philadelphia, James White of Buffalo, T. G. Richardson of New Orleans, John L. Adce of Lancaster, Pa., J. Marion Sims of New York, Dr. Moore of Rochester, Dr. Levis of Philadelphia, Professor Dunster of Ann

Arbor, Dr. Chadwick of Boston; and among the distinguished strangers were Jonathan Hutchinson of London, Dr. Hingston of Montreal, and Dr. Irenholme of Canada.

The sections were officered as follows: (1.) Section of Practice of Medicine, Materia Medica, and Physiology, chairman, J. S. Lynch, M. D., Baltimore; secretary, W. C. Glasgow, M. D., St. Louis. (2.) Section of Surgery and Anatomy, chairman, W. T. Briggs, M. D., Nashville, Tenn.; secretary, C. Powell Adams, M. D., Hastings, Minn. (3.) Section of Obstetrics and Diseases of Women and Children, Professor Morse, St. Louis, chairman (in place of Dr. A. H. Smith, the regular appointee, who was detained by sickness); secretary, Robert Battey, M. D., of Rome, Ga. (4.) Section of Medical Jurisprudence, Chemistry, Psychology, State Medicine, and Hygiene, chairman, James F. Hildebrand, M. D., Richmond, Ind.; secretary, Thomas F. Wood, M. D., Wilmington, N. C. (5.) Section of Ophthalmology, Otology, and Laryngology, chairman, Laurence Turnbull, M. D., of Philadelphia (Dr. Bolling A. Pope, of New Orleans, being absent); secretary, Eugene Smith, M. D., Detroit, Michigan.

The committee of arrangements made several innovations at this meeting. The first was to encroach upon section three, and set aside a room for the meeting-place of those favoring the organization of a separate section for diseases of children, with the intention of creating a separate section next year. This was done, but of course no further business was transacted before this sub-section. The next innovation was the publication of the programme in daily installments, after the method of the British Medical Association. The amount of business to be transacted made this arrangement necessary, and also justified the third innovation, which was the convention of the sections at two P. M. instead of three o'clock, as generally is the case.

It was peculiarly unfortunate that the means and accommodations for the registration of delegates were so poor and inadequate. But a single place of registration was provided, in a small room, and all through the session a long line of delegates stood waiting to enter their names and receive their authority to vote at the meeting. Many of them were obliged to remain in line for over two hours before they could be enrolled as members. For this reason the nominating committee could not be appointed on the first day, as a large proportion of those present were not properly qualified to vote.

About half a dozen lady delegates were present, whose efforts to appear dignified seemed more or less appalling, according to the individual stand-point from which they were viewed, and the approach of the discussion to dangerous grounds.

The entertainments provided were very enjoyable; the size and style of the invitation cards and their number have seldom, if ever, been equalled, certainly not excelled. On Tuesday evening, June 1st, a reception by the members of the medical profession and other citizens of New York was given at the Academy of Music, where Grafulla's Orchestra discoursed most eloquent music; the committee on entertainment and invitations being Dr. Chas. Insee Pardee, Montrose A. Pallen, Robt. F. Weir, Jos. C. Hutchinson, Wm. M. Polk, and E. H. Parker. On Wednesday a complimentary entertainment was given to the members of the American Medical Association and their ladies by

Messrs. Reed and Carrick, Messrs. Scott and Bowne, and the New York Pharmacal Association. On this occasion was presented Othello, with Edwin Booth as Iago. Beautiful silk programmes were distributed. On the evening of June 3d, Mayor Cooper, Mr. August Belmont, and Drs. Fordyce Barker and T. Gaillard Thomas each gave receptions to the delegates. The last-named reception was held at the Academy of Music, and owing to the popularity of the hosts of the occasion it was very largely attended; as, indeed, were those of Messrs. Cooper and Belmont, which were everything that lavish hospitality could make them, to render them enjoyable by the guests.

On Friday afternoon, June 4th, Messrs. Wm. R. Wood & Co. invited the members of the Association upon a steamboat excursion around New York harbor, stopping at Brighton beach.

FIRST DAY'S PROCEEDINGS: GENERAL SESSION.

The meeting was called to order at eleven A. M., June 1st, by the president, Prof. Lewis A. Sayre, of New York, and opened by prayer by the Rev. Wm. F. Morgan, D. D.

Dr. T. Gaillard Thomas, chairman of the committee of arrangements, read a very graceful and chaste address of welcome to the Association, in which, after reviewing the many changes that had taken place in New York during the sixteen years since the American Medical Association held its last meeting in this city, and pointing to the numerous well-appointed hospitals and agencies for the relief of suffering humanity, he claimed for New York at the present day a well-earned reputation for fostering science and the arts. He referred to the characteristics that distinguish this era from all that have preceded it, and considered the leading factors in the improvement to be steam, electricity, and the printing-press. He pointed out that true success in medicine could be based only upon merit, urged professional advancement, and concluded by wishing the delegates welcome, thrice welcome, to New York.

Upon calling the roll of members registered, Dr. Atkinson read the names of 378 delegates, besides a large number of members by invitation.

Dr. Edward Seguin, of New York, presented a report of the foreign delegation on the progress of medical international uniformity, which was ordered to be printed, and made the special subject for discussion on the second day.

The committee on prize essays, chairman, Dr. Austin Flint, reported that only one essay had been received, and that in the opinion of the committee it was deficient in original investigation. No prize was bestowed.

In the address of the president Dr. Sayre pointedly criticised Sydney Smith's famous but unfortunate opinion of American products, and showed conclusively that abundant proof could now be furnished to refute each of his propositions. In reviewing American contributions to medical progress, he spoke of anaesthesia (which he credited to Morton); of ovariectomy, which we owe to McDowell; of litholapaxy, to Prof. Henry J. Bigelow, of which operation he spoke in the highest terms, and said that it is one of which American surgeons may feel justly proud. Sub-periosteal excision, the treatment of spinal disease by rest, and the many other achievements of American physicians in all departments of medicine were each considered in turn. He further advocated the adoption of the metric system

in the practice of medicine; reviewed the history of the establishment of the *British Medical Journal*, and suggested that the propriety of adopting some similar plan for publishing the proceedings of the American Medical Association be taken into consideration.

On motion a committee of five were appointed to consider the recommendation contained in the president's address.

Professor Gross asked for a suspension of the rules in order to perform a solemn duty. He spoke of the recent bereavement of Professor Sayre, and in high terms referred to the many good qualities of Dr. Charles F. Sayre, whose death occurred but a short time ago. On motion of Professor Gross, the society, by a rising vote, tendered sincere expressions of sympathy and condolence with Dr. and Mrs. Sayre in this great affliction.

SECTIONS.

I. Section on Practice of Medicine, etc. Dr. W. H. Thomson, of New York, read an elaborate paper suggesting a revised classification of medicines, which was discussed by Professor Roberts Bartholow, Dr. Mary Putnam Jacobi, and Dr. Thomson.

Dr. M. O'Hara reported a very interesting case of recovery after occlusion of one or more of the cerebral sinuses in a young man twenty-two years of age, whose chief features were neuralgic pains lasting several weeks, followed by a sudden attack of severe pain in the head with edema of the right side of the face and temples, protrusion of eye, and conjunctival ecchymosis; the left side of face soon became involved in this condition; paralysis of right sixth nerve occurred, and throbbing pain was experienced in right side of head; weakness of limbs and want of coordination and varying sensation on the two sides of body were present. General fever, accompanied by local increased temperature, persisted, until the sudden disappearance of the severe head symptoms and the paralysis of the adnexa. Paresis of upper extremities persisted for a week or two. The entire duration of case was about two months. The local temperatures of the head were repeatedly taken, and the case carefully watched throughout its course.

II. Section of Surgery and Anatomy. Spinal Extension, its Modes, Means, and Motives, was presented by Dr. Benjamin Lee, and he exhibited various methods of extension by a sofa-bed and double extension bed that attracted much attention from the section and elicited considerable discussion.

Dr. George M. Beard read a paper on Phimosis as a cause of nervous symptoms, and reported a number of interesting cases relieved by operation.

Prof. John S. Hodges presented the subject of section of the infra-orbital and inferior dental nerve for neuralgia. He proposed to divide the nerve in the infra-orbital foramen. As suggested by Dr. John Green, of St. Louis, the operation is as follows: "An opening being made at the inferior border of the orbit down to the bone, an elevator is then used to separate the soft parts from the orbital plate of the superior maxillary bone, and reaching the posterior border of this surface. The nerve is found lodged in the groove terminating in the infra-orbital canal. With a hook having a curve about one sixteenth of an inch from its end, the groove in the bone at its posterior part is readily found. It is well known that the infra-orbital canal runs almost directly backward from the infra-orbital foramen, and is situated directly under the middle of the palpebral fissure and two lines below the border of the orbit.

"The groove at the posterior part of the canal being found by the blunt hook, the hook is moved to the inner side, and is pressed hard upon the bone and pushed backward until it passes from the posterior border of the orbital plate of the superior maxillary bone, and is then turned outward and made to sweep behind the posterior termination of the groove in which the infra-orbital nerve and artery are lodged. Thus both vessel and nerve are caught in the hook. Straight narrow scissors, guided by the shaft of the hook, are carried backward and between the hook and the orbital plate of the superior maxilla until the nerve is reached; it is then cut." To this original proposition of Dr. Green Dr. Hodgden added the following part of the operation: "It consists in separating the soft parts from the facial surface of the superior maxilla down to the infra-orbital foramen. The blunt hook is made to sweep around this foramen, and thus the infra-orbital nerve and artery at their exit from the bone are hooked up. Using this hook as a lever, the nerve is readily turned out of its canal, and the portion of it which extended from the sphenoidal fissure to the infra-orbital foramen is thus removed. To make sure that the union will not again be accomplished, along this track of removal a needle carrying a double ligature is pressed through the incision below the orbit, and made to terminate in the mouth behind the upper lip. Through the lip, before the ligature is drawn through, is placed the now loosened end of the nerve, and as the loop is drawn through the nerve follows; so that the end which formerly occupied the position at the sphenomaxillary fissure is now lodged on the mucous membrane of the mouth under the upper lip." Very moderate bleeding or ecchymosis follows the operation, but anaesthesia of a certain area will ensue. The other operation, that of section of the inferior maxillary nerve, he proposed and performed thus:—

"With a strong knife a cut one inch long, well down to the bone, is made in the length of the bone, beginning at the base, and a little to the inner side of the most prominent part of the coronoid process of the inferior maxillary bone, and extending forwards. The periosteum is now separated, and the width of the small spear-pointed drill driven by the dentist's engine has its point placed a quarter inch in front of the posterior termination of the incision in the soft parts before mentioned, just below the side of the last molar tooth. The drill is directed downward, backward, and a trifle outward. The firm shell of bone is easily penetrated and quickly passed. Any uncommon resistance to the right or left after coming into the cancellated tissue of the ramus of the bone will indicate to the surgeon that the hard shell on the outer or inner side is being cut. If the drill is spear-pointed as directed, it will not cut through this dense bone of the sides, but will follow the cancellated tissue in the centre. In half a second the canal containing the blood-vessels and nerve will be reached, and, if this is well opened, a severe twinge of pain and the free flow of blood will announce that the nerve and vessels have been cut; and this should be done as soon as possible. The next step of the operation is the withdrawal of the nerve from the canal between the posterior dental and the mental foramen. The incision is made opposite the bicuspid teeth, at the junction of the lips with the gum. The soft parts are then detached with the elevator down to the mental foramen. The blunt hook is made to pass

around the foramen, and thus hook the nerve. The hook is used as a lever to the distal termination of the nerve, being noosed in a loop; the portion occupying the body of the bone is drawn out. Of course this breaks off those filaments that go to supply the teeth."

Twenty-three operations were reported upon twelve patients during the last four years. The results were encouraging.

Dr. Campbell, of Augusta, Georgia, considered that, these neuralgias referred to being generally centric in their origin, permanent good could not be expected from this operation.

Dr. Chas. F. Stillman, of Plainfield, New Jersey, presented some newly devised orthopaedic appliances for weak ankles, and club-foot before or after operation. The apparatus can be attached to an ordinary child's shoe by placing a button in the middle of the sole in front of the heel. The peculiar points of the apparatus are, first, the fact that it has only a single steel rod running up the outer side of the limb; second, its hinge movement is at the heel; the amount of extension of the toes can be regulated at pleasure, being restricted by an elastic band; finally, the rotation allowed at the button corresponds with the normal centre of axial rotation of the limb.

Professor Hingston, of Montreal, praised the ingenuity of the appliance, but did not agree with the statement made as to the pathology of club-foot. In many cases early tenotomy is necessary.

Prof. Wm. H. Paine presented Some Anatomical and Surgical Considerations in regard to Synovitis and Extension in Joints, in which he condemned over-extension of a limb as a source of synovitis.

III. Section of Obstetrics and Diseases of Women, etc. J. Marion Sims, M. D., read a paper on Battey's Operation in Epileptoid Affections, in which he recounted the histories of four operations, three of them for epileptic convulsions and the other for hysterio-epilepsy. In one case convulsions had not entirely ceased. One patient died twenty-two hours after operation, a result which he attributed to the anaesthetic (bromide of ethyl). In all the cases the ovaries were found to be diseased and in an advanced state of cystic degeneration. He has rejected the vaginal operation on account of its difficulty when there are adhesions. He removes both ovaries. An incision three and one half inches long is made in the hypogastrium, between the recti muscles, down to the pubic bone. Then Sims's elevator is introduced into the vagina and canal, and the uterus is bent forwards at a right angle to the axis of the vagina, and is held securely by an assistant. The operator now passes from the fundus the fore and middle fingers along the Fallopian tube, until one ovary is reached; the uterus is inclined a little to the opposite side by the assistant, while each ovary in succession is brought out in front and removed. The operation is performed under the spray of carbolic acid. The pedicle is tied in four sections. Sometimes the Fallopian tube is removed with the ovary. In the cases reported all other remedies had been exhausted, but all the patients expressed great relief, after the operation, from pain and suffering.

This paper was followed by one of the same tenor by Prof. Montrose A. Pallen, of New York, on the True Import of Oophorectomy or Spaying for Reflex Symptoms, more particularly in Epilepsy, Hysterio-Epilepsy, and Catalepsy. In this paper similar conclusions were reached as in the preceding.

¹ See Transactions of the Missouri State Medical Association.

IV. Section of Medical Jurisprudence, State Medicine, etc. The National Board of Health was the subject of a communication by Dr. J. S. Billings, U. S. A.

The Death-Rate of the Rich and Poor was the title of a paper sent by Dr. Chas. Robert Drysdale, of London, in which the evils of overcrowding in poor localities were pointed out as the cause for the difference existing in statistics. He alluded to the large families of poor people, and considered it immoral in its tendencies to have such families, and hoped the time would come when it would be regarded as on a par with drunkenness.

Dr. E. H. Parker, of Poughkeepsie, N. Y., reported three cases of criminal abortion, one causing the death of the mother, in which the guilty parties escaped punishment, owing to a defective law or judiciary.

Dr. A. N. Bell read a paper on Unsanitary Engineering, in which he referred to the ignorance of many builders. An interesting discussion followed this communication.

V. Section of Ophthalmology, Otology, and Laryngology. Dr. W. H. Daly, of Pittsburgh, read a paper on Stenosis of the Larynx, with cases.

Dr. Carl Seiler called attention to the lesions of the larynx in pulmonary phthisis, the turban-shaped epiglottis, the swollen and ulcerated mucous membrane covering the arytenoid cartilages, etc., and exhibited some beautiful microscopic sections of the entire human larynx.

Dr. H. Knapp, of New York, read a suggestive essay on Tumors of the Lachrymal Gland, their Pathology and Operative Treatment, with demonstrations, which was followed by a general discussion.

Dr. E. Seguin presented a paper on the Psycho-Physiological Training of Blotie Eyes, the scope of which is well expressed in the title.

THE MEDICAL EDITORS' ASSOCIATION.

THE fifth annual session of the American Medical Editors' Association was held on Monday evening, May 31, 1880, in the parlor of the Fifth Avenue Hotel. In the absence of the president, Dr. Thos. S. Powell, of Atlanta, Georgia, editor of the *Southern Medical Record*, the vice-president, Dr. Frank Woodbury, of the *JOURNAL*, presided at the meeting. Dr. Dudley S. Reynolds, of Louisville, was appointed secretary, in the absence of Dr. Davis, of Chicago. About thirty editors were present.

Dr. Woodbury, in a short address, called the meeting to order. A communication was received from the Convention of American Medical Colleges, informing this association of the passage of a resolution making three courses of lectures obligatory in all the colleges represented in that body, and requesting the medical editors to promulgate the knowledge of this action. This was received and entered upon the minutes.

The metric system was discussed informally, and a communication from Dr. Baldwin, of Columbus, opposing it, was received and read. On motion the subject was laid over until the next meeting.

The presidential address having been forwarded by Dr. Powell, it was read by Dr. A. N. Bell, of the *Sanitarian*, and resolutions of thanks for the address, and of regret at the absence of Dr. Powell, and condolence for his domestic affliction, were ordered to be transmitted by the secretary.

Drs. Bell, Brodie, and Nelson were appointed nominating committee, who reported the following officers for 1881: for president, Dr. George F. Schrad, of the *New York Medical Record*; vice-president, Dr. F. Nelson, of *St. Louis Archives of Medicine*; secretary, Dr. Dudley S. Reynolds, of *Louisville Medical Record*. Dr. Wm. Hammond, of New York, editor of *Neurological Contributions*, was, on motion, directed to cast the ballot of the association, and these officers were declared unanimously elected. Place of meeting to be determined by the action of the American Medical Association, the time to be the evening before the convening of that body.

— The appointment of Dr. C. F. Folsom, of Boston, and of Mrs. Clara T. Leonard, of Springfield, to the vacancies on the Board of Health, Lunacy, and Charity caused by the expiration of the terms of Drs. Wood and Allen, appears to give general satisfaction.

Dr. Folsom, having resigned the secretaryship of the board in order to pursue the practice of his profession in the specialty of mental diseases, consented to serve as a member of the board at the sacrifice of his personal preferences.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U. S. ARMY, FROM MAY 22, 1880, TO MAY 28, 1880.

HALL, W. R., first lieutenant and assistant surgeon. To report in person to commanding general, Department of the Missouri, for assignment to duty. S. O. 107, C. S., A. G. O.

HARVEY, P. F., captain and assistant surgeon. Granted leave of absence for four months. S. O. 113, A. G. O., May 21, 1880.

RANDOLPH, JOHN F., major and surgeon. Died at Philadelphia, Pa., May 14, 1880.

TESSON, L. S., first lieutenant and assistant surgeon, assigned to temporary duty at cavalry depot, Jefferson Barracks, Mo., relieving Surgeon E. P. Vollum, S. O. 107, C. S., A. G. O.

YEOMANS, ACG. A., captain and assistant surgeon. Died at Toronto, Canada, May 13, 1880.

BOSTON SOCIETY FOR MEDICAL OBSERVATION. — A meeting will be held June 7th, at eight p. m., in the hall of the Medical Library Association. Reader, Dr. Sumner. Subject, Cases of Abdominal Abscess. A. T. CABOT, Secretary.

BOOKS AND PAMPHLETS RECEIVED. — The Diagnosis and Treatment of Obstetric Cases by External (Abdominal) Examination and Manipulation. By Paul F. Mundé, M. D., Obstetric Surgeon to Maternity Hospital, New York, etc., etc. New York: William Wood & Co., 1880.

Health and Healthy Homes. — A Guide to Domestic Hygiene. By George Wilson, M. D. With Notes and Additions by J. G. Richardson, M. D. Philadelphia: Presley Blakiston, 1880.

A Guide to the Examination of the Urine. Designed chiefly for the Use of Clinical Clerks and Students. By J. Wickham Legg, Fellow of the Royal College of Physicians, London, etc. Philadelphia: Presley Blakiston, 1880.

The Management of Children in Sickness and in Health. A Book for Mothers. By Annie M. Hale, M. D. Philadelphia: Presley Blakiston, 1880.

Ophthalmic and Otic Contributions. By Daniel B. St. John Roosa, M. D., Professor of Ophthalmology in the University of New York. New York: G. P. Putnam's Sons, 1880.

Paper on Color Blindness given before the United States Naval Institute. By B. Joy Jeffries, M. D. 1880.

Anniversary Address before the New York State Medical Society, February 4, 1880. By H. D. Dulaney, M. D., President.

Thirtieth Report of the Medical Staff of St. John's Hospital, Lowell, Mass. 1880.

Original Articles.

THE ETIOLOGY OF FEVER.

BY GEORGE L. WALTON AND CHARLES B. WITHERLE.

THE main question presented for discussion in this paper is the relative importance of increased heat production and of decreased heat elimination in the causation of fever temperatures. The prominent pathologists of the present time are about equally divided on this question.

TRAUBE'S THEORY.

Traube's theory, perhaps, embodies best the view that decrease of heat elimination is the chief and primary cause of fever temperature. He assumes a contraction of the superficial small arteries, through irritation of the vaso-motor centre, as the starting-point of fever. In this way is produced a fall of temperature of the skin, that is to say, a chill, and, by the prevention of the normal escape of heat, a rise of the temperature of the body as a whole. The dryness of the mouth and the digestive disturbances are explained by a supposed contraction of the small arteries of the alimentary canal. In the same way, the cerebral symptoms and the lessened excretion of urine are partly accounted for by anæmia consequent on contraction of the vessels of the brain and kidney. The relaxation of the tetanus of the small arteries concerned is followed by sweating, increased flow of urine, fall of temperature, in short, by defervescence.

Those who regard increase of heat production as the chief and primary factor in fever point to the augmented excretion of urea and CO_2 as evidence of this increase; but, to establish their position that it is the more important process, they rely principally on arguments to exclude all other possible views. They admit occasional contraction of the small arteries in the course of fever, but consider this to be of very subordinate importance. They think it incredible that such contraction should be constant during the days and weeks through which a fever lasts.

Traube's followers reply that the existence of a tetanus of the small arteries for days and weeks is less incredible than that any possible increase of heat production should cause a considerable rise of temperature, while the heat-eliminating system remains intact. For it is well known that muscular exercise and the ingestion of food increase heat production; but the heartiest meal or the most violent exercise is followed by slight, if any, rise of temperature, as long as heat can freely pass off from the skin. If, however, the eliminative function of the skin is interfered with, as by a very moist atmosphere, the temperature at once rises.

It is further argued by the opponents of Traube's theory that the bed-clothes of fever patients are hotter, not colder, than normal, showing that more, not less, than the normal amount of heat is given off from their bodies. More precise evidence of increased elimination of heat from the body of a fever patient is furnished by a calorimetric experiment of Leyden's. This experiment will be discussed further on.

Finally, the following experiment of Liebermeister has been supposed by Burdon Sanderson and others to give the death-blow to Traube's theory. A man was placed in a water-bath of the exact temperature of his body. Under these circumstances, no heat is

given off from the body and none is received by it. Liebermeister found that the body temperature soon rose about a degree F., but no more, however long the experiment was continued. In this experiment, it was said, the heat of the body was more completely shut in than it could be by any contraction of arteries; yet the rise of temperature was not comparable to that observed in fever.

Sanderson, in discussing the experiment,¹ says, "The value of this experiment lies in the information it gives us as to the maximum result which can possibly be obtained by mere accumulation of the heat normally produced."

It appeared incredible to the writers that a constant shutting in of the "heat normally produced" should not be accompanied by a constant rise of temperature. Liebermeister's experiment was accordingly repeated, as follows:—

EXPERIMENT I.

On entering the bath, the body temperature was 98.2° F., the same as the temperature of the water. During a prolonged immersion, the maximum temperature of the body was 99°.

The result of Liebermeister was thus confirmed. It soon suggested itself, however, that there was a fallacy in this experiment. When the body temperature is 99°, the water being at 98.2°, the heat of the body is no longer completely shut in, but must pass off to the now cooler water. Therefore, to continue the shutting in of heat, the water must be raised to 99°, the new body temperature. A further rise may then be expected, when again the temperature of the water must be brought up to that of the body, and so on indefinitely.

The following experiment was made to test the truth of this reasoning:—

EXPERIMENT II.

A man, whose temperature, taken in the mouth, was 98.1°, was placed in a bath at the same temperature. The body temperature soon rose to 98.6°. The bath was then raised to 98.6°, and, as expected, the body temperature rose, in this instance, to 99.1°. The following table shows the course of the experiment:—

Temp. of Water.	Temp. of body rose from	Pulse.
98.1°	98.1° to 98.6°	82
98.6°	" " " " " 98.6° to 99.1°	88
99.1°	" " " " " 99.1° to 99.7°	96
99.7°	" " " " " 99.7° to 100.3°	108
100.3°	" " " " " 100.3° to 100.8°	116
100.8°	" " " " " 100.8° to 101.3°	124
101.3°	" " " " " 101.3° to 101.9°	136
101.9°	" " " " " 101.9° to 102.3°	144
102.3°	" " " " " 102.3° to 102.9°	156
102.9°	" " " " " 102.9° to 103.2°	160

The temperatures of body and water were all taken with the same thermometer, and the bath was constantly stirred to insure uniformity of temperature. When the body temperature reached 103.2°, the discomfort was great, and the experiment was discontinued. There was headache, thirst, nausea, weakness, and vertigo.

The pulse and temperature were, it is seen from the table, those of fever, and apparently in this experiment a true fever was present. The temperature of the bath was never higher than that of the body, and consequently no heat could have passed from the former

¹ British Medical Journal, August 9, 1873.

to the latter. A mere shutting in of heat produced all the phenomena observed, and the fallacy of the above experiment of Liebermeister seems to be completely shown.

Moreover, Experiment II. appears to give strong support to Traube's theory, since it shows that a fever may be produced by a mere shutting in of heat, while it never has been shown that one can arise from increase of heat production.

But can it be said that a true fever was presented in Experiment II.? To answer this question, we must consider the scientific meaning which should be attached to the term "fever."

WHAT IS FEVER?

Dr. H. C. Wood, in his Tower lecture on fever, says, "Fever comprehends three classes of disturbances, nervous, circulatory, and thermic; the nervous and circulatory are of secondary importance to the thermic, and as a rule all the symptoms vary with the temperature."

There is, however, a fourth class of disturbances, namely, nutritive, which is clinically recognized to be of the greatest importance. Rise of temperature, if not excessive, in itself only causes discomfort, while it is the nutritive changes that ordinarily represent the exhausting and dangerous effects of long-continued fever.

Experiments show that, corresponding with the increase of destructive-tissue metamorphosis, there is an increased excretion of urea. This increase must be understood as relative to the amount of food ingested, and is not always sufficient, when the patient is subsisting on a minimum diet, to make the absolute amount of urea in twenty-four hours greater than normal.

Ringer found, in intermittent fever, an increase of urea amounting to more than fifty per cent, during the period of chill, and a less marked increase in the period of heat. Unruh¹ found the urea excretion of fever in a large number of cases to be, on the average, seventy per cent. above normal. Numerous other experiments, showing that urea is increased in fever, might be adduced; but it is hardly necessary to multiply quotations in favor of a fact so generally accepted as this is at present.

Here, then, we have a definite and measurable phenomenon accompanying the febrile state, and the writers believe that if urea could be determined as conveniently and accurately as temperature can be measured we should obtain almost as valuable information in regard to the course of fever from examination of the urine as we now do by the aid of the thermometer. It has not been shown that the elimination of urea varies accurately with the temperature; but if it does not, that is an additional reason for its importance, and, *a priori*, one would suppose that an increased elimination of urea without, or with slight, elevation of temperature would be a process of more importance than a rise of temperature, which leaves tissue metamorphosis but little affected.

In regard to the increased production of CO₂ which has been supposed to take place in fever, grave doubts have been expressed by Senator and others from the light of experiments, and the question must still be regarded as unsettled.

E. Wagner says, in reference to the point under dis-

cussion, "Some doubts even begin to be occasionally expressed as to whether increase of body heat is to be made an absolute *sine qua non* for the conception of fever, or whether it would not be better to be content with demonstrating increased tissue metamorphosis."

Senator says, "Rise of temperature is only one symptom, and does not constitute the essence of fever. Its explanation has not as yet furnished any theory of fever, because there are in fever other important processes, independent of elevation of temperature."

Finally, Naunyn says, "It can no longer be doubted that in really feverish states a lasting normal or sub-normal temperature may be produced, if the factor of refrigeration assume the upper hand."

Without attempting to give a rigid definition of fever, it may be said that pathologists are generally agreed that increased-tissue metamorphosis, indicated by increased excretion of urea, forms a part of fever, and that by many it is regarded as not secondary in importance to rise of temperature. If, then, a rise of temperature, unaccompanied by increased tissue metamorphosis, occurs, the condition differs from natural fever by a very important factor. The question last proposed for discussion, namely, Was there presented in Experiment II. a true fever? may now be stated: Did we there have increased-tissue metamorphosis accompanying the rise of temperature? An attempt to answer this question was made in the following experiment:—

EXPERIMENT III.

The experiment extended over four days. During this time one of the writers, who was the subject of the experiment, ate the same kinds and amounts of food each day. The urine was collected every eight hours, measured, and tested for urea. At the beginning of the third day, the experimenter placed himself in a bath at the exact temperature of his body, and remained there for three hours. The whole body, except the head, was immersed. The body temperature soon rose a fraction of a degree, as in Experiments I. and II. The bath was then heated, by adding hot water, to the new body temperature. As fast as the body temperature rose, that of the water was also raised, but the water was never warmer than the body.

The following table will show the course of the experiment:—

TABLE A.

Time.	Temp. of Water.	Temp. of Body.	Pulse.	Resp.
3.30 P. M.	99.1°	99.2°	90	
3.50 "	99.1°	99.4°	98	28
4.10 "	99.3°	99.6°	100	
4.22 "	99.6°	100.2°	102	
4.32 "	99.9°	100.1°	105	
4.45 "	100.0°	100.4°	112	
4.54 "	100.4°	101.2°	116	
5.05 "	101.2°	101.7°	110	40
5.15 "	101.6°	102.2°	120	
5.30 "	101.9°	102.4°	116	
5.40 "	102.5°	102.7°	120	
6.05 "	103.0°	103.5°	132	
6.10 "	98.8°	101.8°	100	

When the temperature was above 100° F., the symptoms of fever were present, intense discomfort and restlessness, flushed face, dry mouth, headache, a state of mind resembling slight vinous intoxication, and at times there was nausea. During and for many hours after the experiment, there was a feeling of great weakness. During the bath two and a half pounds of body weight were lost, the weights before and after

¹ Virch. Archiv, xlviii. p. 268.

the experiment being respectively 159 and 156.5 pounds.

The urea was estimated by Liebig's method with nitrate of mercury. Numerous preliminary tests insured familiarity with the method. In fact, a preliminary experiment, with the same general result as the present one, was made, but not under sufficiently accurate conditions to give it much value. The tests were all made with the same standard solutions, which were those used by Professor E. S. Wood in the laboratory of the Harvard Medical School.

The following table shows the result of the urea tests for the four days of the experiment:—

TABLE B.

		Urine, cc.	Urea, gms.
First Day.	3 P. M.—11 P. M.	310	14.9
	11 P. M.—7 A. M.	293	13.5
	7 A. M.—3 P. M.	408	12.6
	Total,	1017	41.0
Second Day.	3 P. M.—11 P. M.	455	16.2
	11 P. M.—7 A. M.	406	13.8
	7 A. M.—3 P. M.	441	12.8
	Total,	1302	42.8
Third Day.	3 P. M.—11 P. M. ¹	500	20.5
	11 P. M.—7 A. M.	398	17.5
	7 A. M.—3 P. M.	324	14.6
	Total,	1222	52.6
Fourth Day.	3 P. M.—11 P. M.	452	16.7
	11 P. M.—7 A. M.	296	10.0
	7 A. M.—3 P. M.	428	13.7
	Total,	1176	40.4

The average normal excretion of urea per eight hours was 13.8 gms.

It will be seen that for the twenty-four hours including the time of the bath the urea excretion was nearly twenty-five per cent. greater than for any other day of the experiment, and that during the eight hours beginning with the entrance into the bath it was nearly fifty per cent. greater than the average normal excretion for eight hours. The increase lasted for several hours after the experiment. The excretion of urea for the days other than that of the bath was nearly constant.

The amount of urine was not notably affected by the bath, as it commonly is in natural fever; but this is accounted for by the ingestion of large quantities of water, rendered necessary by the extreme thirst, which continued for hours after coming out of the bath. Throughout the experiment water was taken as desired, and not in measured quantities; in this way, it was thought that a constant elimination of urine could be most nearly secured. If constant amounts of water are taken, the variable activity of the sweat glands may cause variations in the elimination of urine, which will, to a slight extent, influence the elimination of urea. It is not the whole amount of water taken which affects the urea elimination, but only that which passes through the kidneys.

The specific gravity of the urine passed just after the bath was 1028, the average specific gravity being 1020.

In the above experiment, none of the characteristic signs or symptoms of fever were absent. The high

pulse and temperature, the rapid respiration, the feeling of heat and restlessness, the cerebral symptoms, the loss of weight, and the increased metamorphosis of tissue, shown by the increased elimination of urea, together constitute a condition which satisfies the most rigid requirements, clinical and pathological, of fever.

The exciting cause of this fever, as we may now call it, was a mere shutting in of heat; but this, though the primary, was not the only cause of the rise of temperature observed. The greatly increased elimination of urea shows that a considerable increase of destructive tissue metamorphosis must have taken place, and this implies an increase in the production of heat. As to how a check of heat elimination causes an increase of heat production, it must be left for the present a matter of conjecture. It is well known that a rise of temperature, which was here initially produced by the shutting in of heat, accelerates almost all chemical processes. Reflex nervous action may also be supposed to play a part, if we admit the existence of trophic nerves. A further discussion of this point would carry us outside the limits of this paper, and we must be content with the fact that, in some unknown way, decrease of heat elimination causes increase of heat production.

We have then, in Experiment III., artificially produced a fever in the same way, in which, according to Traube, natural fever occurs, that is, by shutting in the body heat. This seems to the writers a strong argument in favor of the class of theories to which Traube's belongs, when the fact is considered that it has never been shown that increased heat production can of itself cause fever.

We are now in position to discuss the experiment of Leyden,² which has already been referred to. He showed by a most careful calorimetric experiment on the leg of a fever patient that more heat was given off than from a normal individual. This experiment, it is argued by Leyden, E. Wagner, and others, disposes effectually of Traube's theory, at least as an explanation of the particular fever observed.

It seems to the writers that the experiment is less valuable than has been supposed. Traube's theory assumes a diminution in the function of heat elimination throughout the fever. This implies a lessened giving off of heat at the beginning of the disease. Later, as shown by the increased elimination of urea, much more heat than normal is produced in the body; consequently, though heat elimination is still defective and incompetent to carry off all the superfluous heat, the absolute amount of heat given off may well be greater than normal. To disprove Traube's theory by experiments like that last mentioned, it is therefore necessary to show not only an absolute increase of heat elimination in fever, but also an increase relatively to the new and augmented production of heat. If, in fever, there were constantly a heat elimination less than normal and a heat production greater than normal, it follows at once that there would be a steady rise of temperature without limit. It is not only unnecessary, but absurd, to suppose such a condition of things. It has been shown that at the normal temperature shutting in of heat causes rise of temperature and increased heat production. At the new body temperature there must be, in order to prevent further rise, a sufficiently great increase of heat elimination to carry off the extra heat produced; if increase of heat elimination to a less degree than this occurs, we have

¹ Eight hours, including time of bath. Bath from 3.15 to 6.15 p. m.

² Deutsch. Archiv für klin. Med., v. p. 273.

still essentially a shutting in of heat and a further rise of temperature.

It is not necessary to assume that the tetanus of the arterioles is continuous during fever, which, says one of Traube's opponents, is "contrary to all physiological experience." The temperature of a fever patient is almost always either rising or falling. The disturbance of the heat eliminative system may be supposed to consist in an increased irritation or irritability of the vaso-motor centre, causing temporary tetanus of the arterioles and rise of temperature, followed by partial or temporary relaxation of this tetanus and consequent fall of temperature, as, for example, during the night in typhoid fever. Alternations of tetanus and relaxation explain the rhythmical progress commonly observed in fever. If the onset of the tetanus is rapid, we have a chill, as in intermittent fever; if slow, no chill, as in the diurnal rise of typhoid. If the relaxation of the tetanus is complete or of long duration, the patient returns to a normal temperature; if incomplete or of short duration, a new tetanus occurs, before the refrigerating influence has brought about a return to normal conditions.

As an argument for Traube's theory and its modifications may be mentioned an experiment of Hütter on frogs rendered feverish by the injection of decomposing fluid. In the tongue and mesentery he found, after twenty-four hours, fully one half the capillaries filled with red blood corpuscles, and excluded from the circulation, the heart meantime working with its normal force.

SUMMARY.

To sum up the results of the whole discussion, the following seems to the writers the most probable view of the origin of fever, if further experiments should confirm the results of those described above:—

Through irritation of the vaso-motor centre a tetanus of the smaller superficial arteries occurs, which, by diminishing the circulation in the skin, shuts in heat. The onset is accompanied by a chill or not, according as the tetanus occurs suddenly or gradually. In some unknown way an increased production of heat is caused by the shutting in of heat. This increased heat production must be regarded as of much more importance than it was considered to be by Traube. Throughout the periods of rising temperature there is decreased activity of heat elimination relatively to the new and increased rate of heat production. The elimination of heat may or may not be absolutely decreased. Even with tetanus of the arteries and rising temperature the excessive heat production may be enough to make the absolute amount of heat eliminated greater than normal; but, during the rise, incompetency of the heat-eliminating system, dependent on tetanus of the superficial arterioles, remains a cause of the rise and of the increased heat production. Exhaustion of the tetanus is followed by a more or less gradual increase of heat elimination and fall of temperature, to be followed in turn, if the fever continues, by a second tetanus and rise of temperature.

In favor of this modified form of Traube's theory it may be said:—

(1.) That the fact of greatly diminished circulation in the skin has been shown by Hütter in the septic fever of frogs.

(2.) That this theory only assumes a derangement of a well known physiological function, namely, that

of the vaso-motor centre, while no centre for heat production has been demonstrated.

(3.) That it has been shown in Experiment III. that a fever can be produced by a primary shutting in of heat, while it has not been shown that increased heat production can of itself cause fever.

(4.) That this theory retains all the advantages of Traube's original one in explaining the clinical and pathological phenomena of fever.

(5.) That it is free from the objectionable assumption of Traube that there is in fever patients a tetanus of the arteries, lasting for days and weeks.

(6.) That it is not inconsistent, as Traube's theory is, with the result of Leyden's calorimetric experiments on fever patients.

(7.) That shutting in of heat will, as has been shown in Experiment III., account for the great increase in the elimination of urea which is observed in fever.

With regard to the practical bearing on medicine of the question which has been discussed a few words will be ventured, though not strictly admissible under the subject of the paper.

If increase of heat production is the primary disturbance in fever, treatment by cold baths is apparently of service only by giving comfort to the patient and occasionally preventing those excessively high temperatures which seem to be in themselves dangerous to life. The baths cannot be supposed, if we take this view, to be of any service in checking the production of heat and destruction of tissue.

If, on the other hand, decreased heat elimination is primary to and the cause of the destructive-tissue metamorphosis, as it was shown to be in the artificial fever of Experiment III., then cold baths, by increasing heat elimination, directly tend to remove the primary cause of fever.

SUDDEN AND TRANSIENT SWELLINGS OF THE LIPS.¹

BY T. B. CURTIS, M. D.

THE affection which is the subject of this communication is in itself, I must confess, rather a trivial one. Certain considerations will, however, I trust, suffice to show that it is not altogether devoid of interest to the practitioner and to the student. In the first place, without being really rare, it is sufficiently uncommon to have escaped the observation of many experienced physicians. In the second place, it has not obtained, so far as I have been able to learn, any distinct recognition in medical literature; it has no nosological position; in a word, no name. Hence the necessity of the descriptive, symptomatic designation which serves as the title of my paper. Finally, although invariably of short duration and favorable termination, this little disturbance, by the suddenness of its onset and by the inconvenience and deformity which it occasions, is apt to cause a considerable degree of alarm to the patient. It then becomes very desirable that the physician, when consulted, should be able to recognize at once the nature and harmlessness of the trouble, if only for the sake of reassuring the patient. Relying, then, upon these features of interest, I venture to occupy the attention of the society this evening with a few remarks upon this nondescript and nameless ailment.

¹ Read before the Boston Society for Medical Improvement, April 26, 1880. See JOURNAL May 6th.

The affection which I propose briefly to describe presents for consideration in most cases but one symptom, namely, a sudden and transient, circumscribed, painless swelling of the lip. The onset seems to take place mostly in the night, for nearly all the patients whom I have seen, numbering from twelve to fifteen cases, had first become aware of the existence of the trouble in the morning on awaking. The swelling would then be already fully developed and very considerable; or it might be moderate in degree, and continue for a few hours to increase. All my cases have occurred among the poor, in dispensary or hospital out-patients, in Paris and in this city. The swelling was in most cases very great, occupying the entire upper lip, or the lower lip, or the commissure and the greater part of both upper and lower lips, and gradually fading away, without distinct limit, upon the cheek. The lip so affected is enlarged in every way, greatly thickened and elongated. Its consistency is quite hard and firm. There is little or no tenderness, and pressure does not cause pitting. The swollen lip stands stiffly out, and remains quite motionless when attempts to shut the mouth or to speak are made. As consequences of this state of things, there is a very marked degree of deformity, rendering the sufferer at once hideous and ridiculous. A good deal of inconvenience also exists, resulting from the stiffness of the protruding lip, and the consequent inability of the patient to effect the usual movements of the part. Articulation is thus rendered indistinct, drinking is made difficult, and even the act of swallowing may be hindered, on account of the impossibility of making the necessary vacuum within the mouth. Another uncomfortable result is a continual overflow of saliva. In most cases nothing more is discovered on examination. The patient is alarmed by the suddenness of the attack and by the conspicuous character of the deformity, and he complains only of the feeling of clumsiness, tension, and rigidity of the swollen part, and of the inconveniences resulting from its displacement and immobility. In a few cases, however, there are some additional manifestations. There may be a little pain and tenderness and a trifling degree of redness of the integument; also some increase of warmth. In a word, the characteristic elements of inflammation are present, heat, redness, pain, and swelling. The latter, however, greatly preponderates, and generally constitutes the whole disease.

The trouble from the first and throughout remains purely local in character, and confined to the part in which it originated. I have never seen any sign of general disturbance, such as fever, indigestion, or sickness of any kind. Neither have I observed any complication or sequel. Adenitis, in particular, has always been absent. The course of the affection seems to be invariably the same. The swelling, having attained its fullest development in a few hours, persists for a day or two, and then gradually subsides, disappearing wholly within a total duration of twenty-four, thirty-six, or forty-eight hours.

In all the cases of sudden and transient swelling which I have come across among my own patients, the lip has been the seat of the disturbance. In one case, however, for which I am indebted to Dr. Bradford, who kindly sent the patient to me from the dispensary, a similar painless swelling occupied the right half of the forehead. The appearances were such as to cause Dr. Bradford to suspect erysipelas at first

sight, but the suddenness with which the swelling arose and subsided within forty-eight hours and the absence of other inflammatory and febrile symptoms made him renounce this suspicion in favor of the view that the affection might be of a similar nature with the ephemeral swellings of the lip, of which he had already seen several examples.

With regard to the circumstances which might throw light upon the *etiology* of this affection, I would say, first, that *sex* and *age* play no part in its causation, for I have seen it in children and grown-up people, both male and female. *Season*, however, does seem to exert a distinct influence, if I may trust my own experience. All the cases that I have seen have occurred in the spring or summer months. I have often interrogated patients with a view to discovering some accidental circumstance which might supply a plausible determining cause for the attack. In a few cases exposure to cold, such as might result from the neighborhood of an open window, was incriminated, but the evidence in favor of this agency was generally uncertain. The state of the teeth I have always carefully examined, without finding any connection between the attacks of lip swelling and the existence of caries, alveolar periostitis, or gingivitis. In no instance was toothache complained of, and in some cases the condition of the teeth was faultless. Several patients have attributed the attack of swelling to the bite of a spider, but upon questioning them with care this agency turned out to be purely imaginary.

A few years ago, when attending the surgical out-patients at the Massachusetts General Hospital, several patients presented themselves with swelled lip. One of my assistants having asked under what diagnosis the cases should be recorded, I was obliged to confess that I did not know the name of the disease, and begged him to look it up in his text-books, and inform me of the result. He failed to find any mention of such an affection, and on making researches and inquiries myself I was equally unsuccessful. In the Paris hospitals such lip swellings were called *fluxions*, an old-fashioned term of vague significance, which exists also in English. In Duglison's Dictionary a fluxion is defined as "a flow of blood or other humor towards any organ with greater force than natural." In Littré's edition of Nysten's Dictionary a fluxion is similarly defined as "a determination of a liquid towards a point under the influence of a local exciting cause," and as an example, the phlegmonous swelling of the cheek and gums, attending diseased teeth, is cited. "Often, however," adds Nysten, "fluxions, instead of being of a phlegmonous character, are simply œdematous; they are unattended by pain, and ordinarily are due to the influence of cold and damp air exerted upon more or less decayed teeth, which, however, are not at the time the seat of any pain." Magiot, a well-known French writer upon dental surgery, says that "a simple subacute periostitis may give rise to the œdematous swelling of the face commonly called a fluxion. When acute it occasions a circumscribed or diffuse phlegmon." The word fluxion seems then to designate properly an incipient or aborting cellulitis or phlegmon of the face.

Continuing my researches, I found that the only lip swellings that were generally recognized were, in the first place, the acute inflammatory form which attends furunculus of the lip; and, secondly, the chronic enlargement or so-called *hypertrophy* of the lips, which is

met with in scrofulous children. Both of these are unmistakable affections, having little or no resemblance, save in external appearance, to that which I am now describing. The same may be said of the *cheilitis glandularis apostematosa*, of which several cases have been reported by Volkmann,¹ and of the *chronic hypertrophy of the lips*, described more recently by Dr. R. W. Taylor,² of New York. These, like the strumous enlargement of the lip, are chronic affections, long lasting, if not permanent, and are therefore very different from the fleeting ailment which I have in view. A careful search through special treatises³ yielded only negative results.

My investigations were not, however, wholly fruitless, for I came across several descriptions of an affection not without analogy to that which I was seeking to identify. Several observers have recorded cases of an unusual character, in which patients had been liable for more or less long periods of time, weeks or months in duration, to undergo repeated attacks of sudden, ephemeral, painless swelling, situated upon the face, as well as upon other parts of the body, and occasionally affecting the lips. This form of disease was first described, I believe, by Graves,⁴ in a clinical lecture on gout. The case is related by him as follows:—

"Gout is another disease which occasionally exhibits examples of its peculiar inflammations, attacking various parts and tissues of the body, and that for an extremely short period of time. . . . One of the most remarkable instances of fugitive inflammation affecting various parts of the body which has come under my notice occurred in the person of a gentleman lately under my care. . . . of a gouty habit. . . . After laboring for some time under languor and weakness, accompanied by spasms, pain, and sense of weight in the stomach, the pain of the stomach ceases, and his face begins to swell at various points, generally commencing on the forehead, and involving the cheek and eye, so as to close up the latter. . . . He suddenly perceives a tumor rising on the forehead, which, in the space of half an hour, becomes as large as a pigeon's egg, and, as he expresses it, moves down until it closes the eye. Sometimes it attacks his lips and other parts of his face, but never affects his nose. But what is chiefly remarkable in this case is the singular character of the local affection. The tumors arise, run through their course, and disappear in the space of a few hours, and on the following day there is no trace of their existence. Sometimes the lips, inside of the mouth, palate, and uvula are attacked, giving rise to very considerable inconvenience. Were such tumors to occur in the neighborhood of the glottis, I need not say that they would be pregnant with danger of no ordinary character."

The same unusual form of gouty disturbance was recently described in the following passage from a lecture On the Gouty Vice,⁵ by Dr. W. H. Draper, who may have owed his information on this particular point to Graves:—

"The lesions of the skin, says Dr. Draper, which occur in gouty subjects may be divided into those which depend upon sudden and transient disturbances of the cutaneous circulation, and those which are the consequence of prolonged hyperæmia. Examples of the former class are observed in some of the forms of erythematous lesions, as, for instance, in urticaria, and in that more rare and curious affection of the same fugitive character, which occurs generally about the face, in which sudden swelling takes place in the eyelids, closing the eyes, or in the cheek and lips, or perhaps in the tongue or soft palate, causing marked but transient deformity, and sometimes considerable inconvenience and suffering. In these forms of erythema, the

hyperæmia is temporary, lasting only a few hours, and leaving no trace. It should also be remarked that these lesions in gouty subjects are generally excited by indigestion, and especially by the irritation, either direct or reflex, produced by certain articles of diet, such as certain kinds of fish, or fruits, or wines."

Dr. Draper calls attention in the foregoing passage to the analogy or relationship existing between the sudden and transient swellings of gouty subjects and certain erythematous disturbances of the skin, among which he mentions urticaria. A curious case, which seems to bear out this view, was reported⁶ under the title of Unusual Form of Urticaria, by Mr. J. L. Milton, as follows:—

"The following very unusual case seems to me more clearly connected with urticaria than any other disease of the skin. That it was a neurosis I think admits of no doubt. The singular features in it were the extraordinary size of the swellings and the total absence of all itching. I showed it to several surgeons, but no one recognized the disease except Sir B. Brodie, who had seen one or two instances of it in a very mild form, but confessed himself so entirely puzzled as to its nature that he had not ventured to give it a name. I believe no published account of the disorder is to be found; at any rate, I found none after a long search in the library of the College of Surgeons.

"Case: The patient was a gentleman, aged thirty-five, usually enjoying very good health, though rather below par, owing to overwork. In June, 1855, colicky pains and neuralgia, followed by a series of swellings, sudden and transient, lasting a few hours, situated on the thighs, lips, and over the crest of the ilium. Sometimes two occurred almost simultaneously; on one day there were three. In October the face was attacked. A hard swelling passed slowly over both eyes. . . . It ran its course in about eight hours, and then slowly subsided, but considerable puffiness remained for several days. Each eye in succession was firmly closed by the swelling. A few days after the mouth was assailed, the swelling being much more prominent. One or two swellings also showed themselves on the legs, and one or two small ones on the arms. There was now generally an interval of a day or two between them, and after a few irregular outbreaks the disorder entirely quitted the lower part of the frame, to appear with concentrated violence in the face.

"Here, after three attacks, the disorder fairly reached its climax on the 11th of December. About four A. M. a swelling commenced, with a peculiar sensation of tension and uneasiness in the left cheek, which soon roused him, and prevented further sleep. On grasping it with the hand it felt like a large walnut. It spread with the most astonishing rapidity, and by eight o'clock had reached right across the lower part of the face, which was so swollen as to be visible like a dark, projecting shadow on 'casting down the eyes. The anterior surface of the upper lip was protruded horizontally outwards, and firmly pressed against the nostrils; the mucous membrane of the lips was shining, and so tense as to feel as if it would crack. All attempts at articulation were very imperfect, and though the mouth was not firmly closed, yet nothing could be swallowed, owing to its rigidity and to total loss of control over the movements of the lips."

"Three times the throat was affected, and here the swelling reached its maximum in half an hour. A medical friend, whose aid was sought in one of these attacks, said that the posterior fauces presented much the same appearance as in a bad case of cynanche, the uvula, soft palate, and tonsils being greatly swollen. Saliva was poured out in large quantities, and for some hours the sense of suffocation was almost unbearable. . . . From the 11th of December the number and severity of the attacks steadily declined, and they finally disappeared on the 11th of March.

"At no time were these swellings painful, even on firm pressure, to which, I may here observe, they did not yield. Some of them conveyed a feeling of heat to the hand, but in general the only sensation remarked was one of stiffness and distention. The skin was for the most part unaltered in color. . . . The subsidence of the swelling was never followed by any desquamation or itching. . . . No constitutional disturbance of any kind accompanied either the outbreak or decline of these singular phenomena. . . . Sir B. Brodie considered the affection dependent on disorder of the stomach, remediable by the use of liquor potassæ. . . . None of these swellings ever formed in the afternoon or evening. All those of which I noticed the commence-

ment began between four and ten A. M., and with one exception always reached their utmost height in four hours.*

The disturbances thus described by Mr. Milton were considered by him to be very unusual, as he had himself never seen nor heard of such a case before. Sir B. Brodie, however, had seen one or two instances of a similar nature in a milder form, and probably considered the disorder to be of a gouty character, since he attributed it to a digestive disturbance, likely to be remedied by the use of liquor potassæ.

An affection similar to that observed by Graves and Milton, and consisting in a series of attacks of sudden and transient swelling, painless, and of short duration, occurring successively during a period of several weeks or months, situated in different parts of the body and face, and occasionally affecting the lips, has been described by Perroud,¹ of Lyons, in a paper on Ephemeral Congestive Tumors of the Skin, to which Dr. J. C. White kindly directed my attention quite recently. Perroud's cases, five in number, seem to have been identical in character with those reported by Graves and Milton. In fact, he cites Graves's case of sudden swellings occurring in a gouty subject as one of the observations upon which his description of the disease is based. He considers the disturbance to consist in localized congestions taking place under the predisposing influence of a constitutional vice, and ascribes as the cause in some cases a gouty diathesis, in others scrofula or a "lymphatic temperament." The evidence of constitutional vice was for the most part equivocal, and in one of his cases no such predisposing diathesis could be incriminated.

The individual successive attacks which took place in the cases recorded by Graves, Milton, and Perroud seem to have been very similar to the single attacks which I have observed. In none of my cases, however, was there any repetition of the morbid process, nor has it been possible to recognize any particular constitutional defect as the predisposing cause of the local trouble.

With regard to the nature of the morbid process which occasions these sudden and transient painless swellings we are of course reduced to surmises. The increase of bulk of the affected part recalls that caused in other localities by *œdema*, with this peculiarity, that here pressure does not cause pitting. It may be observed, also, that the lips seldom, or never, participate in *œdema* of the face, being sometimes, in cases of dropsy or erysipelas, the only parts of the face that escape the infiltration. Their exemption from such rapid *œdematous* swelling as takes place in the eyelids and cheeks is perhaps due to their firm texture and to the paucity of connective tissue entering into their structure, the lips being largely composed of muscular fibre closely united with the under surface of the skin.

The process is evidently of an inflammatory character, as is shown by the sudden and acute course, and also by the presence of heat, pain, and redness occasionally accompanying the swelling in moderate degrees. We might perhaps attribute the disturbance to an acute reticular lymphangitis. Chassaigne² has expressed the opinion that the thickening of the lips observed in scrofulous children was due to a reticular lymphangitis, and Dr. Curnow,³ in his recent lectures

on the lymphatic system, says that he is inclined to include with reticular lymphangitis the "acute swelling of the lips and tip of the nose which is so common in strumous people."

The diagnosis of this ailment is readily made, provided only that the practitioner is forewarned of the existence of such an affection. The absence of any disturbance except the swelling itself suffices to set aside the existence of erysipelas, furunculus, or urticaria. The sudden onset and the rapid subsidence of the swelling are incompatible with the idea of a serofulous enlargement of the lip. The acute, gouty swellings of Graves, Draper, and Milton seem to be so similar to the affection which we are considering as to be probably undistinguishable from it, save by the frequent repetition of the process and by the evidences of constitutional disturbance. They are, however, very rarely seen, and may perhaps be considered as highly aggravated and exceptional forms of the same disease.

The prognosis, it is hardly necessary to add, is invariably favorable, since the swellings may be expected to disappear spontaneously in a few hours, or at the latest in a day or two. No treatment, except perhaps the avoidance of exposure to cold, seems to be called for. The sufferer may prefer to keep the house till the very unsightly deformity has subsided. The most important office of the physician consists in dispelling the needless alarm of the patient. That he may be able to render this little service he must be prepared to recognize the affection and to foretell its issue. The object of my remarks upon the subject of ephemeral swellings has been mainly to impart the familiarity which breeds contempt.

Reports of Societies.

SECOND ANNUAL CONVENTION OF THE AMERICAN LARYNGOLOGICAL ASSOCIATION.

THE second annual convention of the American Laryngological Association was held in New York, May 31st, and June 1st and 2d.

On the first day, in the absence of the president in Europe, Dr. Cohen, of Philadelphia, was called to preside over the meetings of the association. An address of welcome was then delivered by Dr. Leferts, of New York. Dr. Cutter, of Boston, read a paper on

THROAT SYPHILIS AND TUBERCLE,

reiterating his well-known devotion to the theories of Dr. Sansbury. Demonstrations of micro-photographs of the blood in these diseases were given by the aid of the magic-lantern in the evening. The second paper of the morning session was on the treatment of

PHARYNGITIS SICCA,

by Dr. Sharley, of Detroit, for the treatment of which, among other things, he specially recommended the employment of the constant current of electricity. In the afternoon the first paper was by Dr. Leferts, of New York, on

THE USE OF THE LARYNGOSCOPE IN CHILDREN,

claiming that a good view of the larynx could and should be obtained much oftener than it is. He recommended tact and persuasion at first, and when these failed a resort to force. In the discussion which followed, the importance, value, and accuracy of a forced

¹ Annales de Dermatologie, etc., Paris, 1869, page 193.

³ Lancet, April 12, 1879, page 508.

examination of the child's larynx were well illustrated by a case of Dr. Warren's at the Massachusetts General Hospital, in which Dr. Knight had been able to diagnose paralysis of the posterior crico-arytenoid muscles (as distinguished from spasm), a condition requiring immediate tracheotomy. The correctness of the diagnosis had been established by the fact that the patient had continued to wear the tube, though years had elapsed since the operation. Dr. Lincoln said that he was in the habit of making a laryngoscopic examination of children by holding the head between his knees, direct light from a window being employed. Dr. Beverley Robinson, of New York, read a paper on

THE THERAPEUTICAL VALUE OF REST IN THE TREATMENT OF LARYNGEAL DISEASES.

In the discussion which followed this paper, while there was a general agreement as to the desirability of as complete a rest as possible from localization during acute affections of the larynx, some members were of the opinion that moderate exercise of the voice might not only do no harm, but perhaps be of positive benefit in chronic catarrhal conditions in which there was no evidence of muscular inability. Cases of the latter class might require temporary rest. Dr. Robinson called attention again in this paper to the rapid improvement after tracheotomy in cases of laryngeal perichondritis. Dr. E. W. Cushing, of Boston, exhibited an interesting and rare specimen of

MEMBRANOUS LARYNGITIS,

which had occurred as a complication of typhoid fever.

In the evening an elegant dinner was given by the New York Fellows to their colleagues at Delmonico's. At the morning session of the second day there was a business meeting, at which reports of various committees were disposed of. The committee on nomenclature, in consideration of the extent and important nature of their work, were granted another year in which to make their report.

Several amendments to the constitution were acted upon, one of those accepted providing for a second vice-president and a librarian. Dr. Knight then, as chairman of the nominating committee, reported the following list of officers for the ensuing year: president, J. Solis Cohen, of Philadelphia; vice-presidents, W. C. Glasgow, of St. Louis, and J. O. Roe, of Rochester, N. Y.; secretary and treasurer, G. M. Lettels, of New York; librarian, F. H. Bosworth, of New York; member of the council to fill vacancy, Dr. A. H. Smith, of New York. This committee also recommended Philadelphia as the place of meeting for 1881. On recommendation of the council the following gentlemen were elected active Fellows of the society: Dr. Harrison Allen, of Philadelphia, Dr. C. E. Bean, of Louisville, Dr. E. W. Cushing, of Boston, Dr. W. H. Daly, of Pittsburgh, Pa., Dr. W. Gleitsmann, of Asheville, N. C., Dr. W. C. Jarvis, New York, Dr. S. M. Langmaid, of Boston, Dr. C. E. LaJaux, of Philadelphia. Manuel Garcia, of London, was elected an honorary Fellow of the society.

A letter from the absent president, Dr. Elsberg, written on a sick-bed at Aix-la-Chapelle, was here received and read. The society passed resolutions of sympathy for their president in his sickness, and wishes for his speedy restoration to health.

Dr. Rumhold, of St. Louis, exhibited

A NEW FORCEPS

for removing polypoid growths from the superior respiratory tract.

A letter from Dr. Mandl, of Paris, was read, in which he expressed wishes for the welfare of the society and the specialty, and signified his donation of books to the society's library.

At the afternoon session Dr. Cohen, of Philadelphia, read a paper on

PRIMARY TUBERCULOSIS OF THE LARYNX,

which was illustrated by the large, beautiful microscopic sections of Dr. Seiler. Dr. Cohen, while admitting that primary tuberculosis of the larynx was very rare, and possibly still open to question, said that the case which formed the topic of his paper presented such clinical features as made him feel that the disease began in the throat, the first symptoms being a difficulty in swallowing.

Dr. Knight, while admitting that in this case Dr. Cohen was probably correct in his diagnosis, in this connection warned the society against assuming that there was no pulmonary disease in a given case simply because there were no morbid signs to be detected by auscultation and percussion. He said it must be remembered that only gross pulmonary lesions, or those situated near the surface of the lung, were necessarily evident on physical examination.

Dr. F. H. Bosworth, of New York, read a paper upon

NASAL STENOSIS,

in which he strongly recommended the employment of galvano-cautery in the treatment of hypertrophy of the anterior portion of the lower turbinated bone.

Dr. Daly, of Pittsburgh, while indorsing the use of galvano-cautery, recommended care in its employment, as he had known erysipelas and inflammation of the middle ear to follow its free use. Touching the swollen membrane with the wire at a red heat, without attempting to destroy it, seemed in many cases to suffice by promoting absorption.

On the third day Dr. Seiler, of Philadelphia, read a paper on a case in which a simple papilloma of the larynx seemed to have been irritated into malignancy by injudicious local treatment. Dr. Seiler also exhibited a new laryngeal forceps, capable of being bent and opened in any and every direction, apparently the greatest improvement in laryngeal forceps for many years.

Dr. Roe, of Rochester, read a paper on

FRACTURE OF THE LARYNX,

and showed a specimen. A paper of Dr. Ingals, of Chicago, on The So-Called Swallowing of the Tongue, was read by the secretary. Dr. Langmaid, of Boston, read an exceedingly interesting paper, and one which received the closest attention of the society, on The Treatment of Certain Forms of Vocal Disability by the Application of the Principles of Vocal Culture.

In the afternoon Dr. Daly, of Pittsburgh, read a paper on Nasal Polyps, and Dr. Jarvis, of New York, one on Hypertrophy of the Nasal Mucous Membrane. The latter recommended the removal of the hypertrophied mucous membrane of the posterior ends of the turbinated bones by means of a wire caesarean, fine No. 5 piano wire being used. He showed several large

masses which had been removed in this way from the turbinated bones, with complete relief to the nasal obstruction. After voluntary narration of cases and exhibition of patients by several members, the officers nominated on the previous day were elected and inducted into office, and Philadelphia was accepted as the place of meeting for next year. The convention then adjourned.

The Fellows of the association were guests of the American Medical Association at all the entertainments given by, or provided for, the latter. The meeting was a thoroughly successful one in every respect, whether socially or scientifically considered. It was harmonious, business was dispatched quickly, members were prompt with their papers, which as a rule were excellent, and the discussions were to the point, receiving the compliment from a professor of the University of Pennsylvania of being conducted on a much higher plane than those of the sections of the American Medical Association.

ANNUAL MEETING OF THE AMERICAN MEDICAL ASSOCIATION.¹

SURGICAL SECTION. FIRST DAY.

The first paper before the surgical section was that of Dr. Benjamin Lee, of Philadelphia, on Spinal Extension: Its Modes, Means, and Motives.

Extension of the spinal column was stated to be as old as the "Old Man of Cos," who, with his wonderfully acute and profound intellect, was able to appreciate the advantages of mechanical therapeutics, in later times degraded from its true place by the mysticism of the Middle Ages, from which the profession is still struggling to emancipate itself.

The modes of spinal extension were described as three: vertical, inclined, and horizontal. Diagrams of different apparatus from the time of Hippocrates down illustrated the means for carrying out each of these modes. The latest of these was the surgical table of Mr. W. H. Johnstone, of Philadelphia, constructed at the writer's suggestion for the purpose of taking a plaster cast of the trunk in the horizontal position, but susceptible of being employed in the reduction of fractures and dislocations, and in the performance of operations requiring the limb to be firmly fixed. The motives of spinal extension were either direct and immediate, or indirect and mediate. The direct objects were, first, the reduction of dislocations and fractures of the vertebrae; second, the stretching of contracted muscles and ligaments, along the spinal column; and, third, the restoration of tone and contractility to relaxed muscles and ligaments.

The importance of making use of extension, either by suspension or horizontal traction, in every traumatic lesion of the spine of a paralyzing character was especially insisted on, the risks of the operation being asserted to be small in comparison with those attending its neglect. The mode of making use of the table for the purpose of taking a plaster cast in order to produce a mold for making the Powers felt jacket was described with some minuteness.

Dr. Lee thought that while the table of Mr. Johnstone was a very perfect and convenient apparatus for this especial object, as a means of daily exercise it was not likely to produce as good results as the spinal swing.

¹ Continued from page 552.

SECOND DAY.

Morning session. The proceedings opened with a breeze in regard to the admission of the delegates from the United States navy; Dr. Gihon claiming that charges had not been properly placed before the judicial council. On motion of Professor Gross, the representatives of the medical department of the navy were admitted to full membership, in default of any legitimate complaint having been filed against it before the council.

A committee on nominations was appointed as follows:—

W. O. Baldwin, Alabama; E. R. Du Val, Ark.; M. S. Storrs, Conn.; Judson Gilman, Md.; W. S. Tremaine, Kansas; Marshall Sexton, Indiana; J. B. Book, Mich.; Jos. H. Warren, Mass.; E. M. Moore, N. Y.; Duncan Eve, Tenn.; S. D. Gross, Pa.; I. H. Pope, Texas; J. Eliot, D. C.; T. G. Richardson, Louisiana; Dr. Wakefield, Florida; A. T. Woodward, Vt.; H. B. Ransom, Iowa; G. A. Shurtleff, Cal.; F. D. Cunningham, Va.; S. Baruch, S. C.; C. P. Adams, Minn.; M. Campbell, W. Va.; J. G. Thomas, Ga.; William Marshall, Del.; G. W. Nesbitt, Ill.; A. E. Heighway, Ohio; T. G. Robinson, Mo.; R. E. Howard, Miss.; H. A. Hopper, N. J.; G. P. Conn, N. H.; A. Ballou, R. I.; Walter Kempster, Wis.; W. K. Oaks, Me.; J. A. Oetzel, Ky.; J. S. Billings, U. S. A.; and J. Rufus Tryon, U. S. N.

Dr. Brodie, one of the delegates to the Canada Medical Association, reported their attendance upon the meeting of the Canada Medical Association, and their flattering reception by the members. The report was accepted.

The propositions contained in Dr. Chaille's address of last year were reported upon unfavorably by the committee appointed at Atlanta. In regard to the propriety and expediency of the publication of the Transactions in periodical form, the committee were divided; but this subject will be further considered.

A letter from Dr. N. S. Davis, of Chicago, was read, regretting his enforced absence, and recommending that for the purposes of the investigations of the committee on ozone this committee be authorized to purchase instruments of precision, whose value shall not exceed \$200. On motion of Professor White, of Buffalo, the committee was continued and the appropriation made.

The address of the chairman of the section on Practice of Medicine, Dr. J. S. Lynch, of Baltimore, was listened to with much interest. He reviewed some of the points in regard to yellow fever, and concluded that it could not be destroyed by cold. Moreover, when first discharged from the system by the excretions, the poison is in a potential state, but after a certain period of about sixty days it is found to have undergone some change, rendering it active and capable of imparting the disease. He insisted upon the necessity of prophylaxis and prompt disinfection, thorough in its application. The lecturer called attention to the great mortality from consumption, and insisted that the observations of Professor Bowditch and others had indicated the proper method to pursue in order to reduce its ravages. Scarlatina and diphtheria are also preventable diseases, and demand our attention. More fatal cases occur annually from the preceding diseases than during the yellow-fever epidemic of 1878, and they excite comparatively little public interest. He referred also to the cinchona alkaloids and salicylic

and carbolic acids as antipyretics, and to the physiological action of aconite in explaining its influence upon febrile conditions.

In the report of the chairman of the section on Surgery, Dr. W. T. Briggs, of Nashville, discussed particularly the subject of trephining, especially as a preventive, or as a precautionary measure in severe traumatism of the head, where it was feared that extravasation of blood, inflammation, or other bad results may follow. Of forty-two cases trephined by him, thirty-eight recovered. His conclusions were as follows:—

(1.) Extensive comminuted depressed fractures of the skull were almost invariably fatal without operative measures; (2.) curative operations were but little better than the expectant plan of treatment; and (3.) preventive trephining offered the best chances for a successful operation. Dr. Briggs then discussed the question of the treatment of punctured and simple fractures of the skull, fractures of the external and of the internal table, and stated as the essentials to success: (1) full antiseptic precautions; (2) the use of the conical trephine; (3) entire removal of all loose fragments of bone; (4) special attention for the purpose of securing perfect drainage, the open-wound treatment being his favorite method.

The following important amendment relating to prize essays was adopted:—

(a.) There shall be four annual prizes of two hundred and fifty dollars each, which shall be awarded at the close of the second year after announcement, as hereinafter explained, for strictly original contributions to medical and surgical progress.

(b.) It shall be the duty of the chairman of each of the following four sections—(1) Practical Medicine, Materia Medica, and Physiology; (2) Obstetrics and Diseases of Women and Children; (3) Surgery and Anatomy; (4) State Medicine and Public Hygiene—to appoint annually, before the adjournment of the meeting of the Association, three members of ability and good judgment, who shall constitute a committee of selection, and who shall, within thirty days thereafter, select and publicly announce for competitive investigation and report a subject belonging to one or other of the branches of medicine included in the title of the section.

(c.) It shall also be the duty of the chairman of each of the sections mentioned to appoint annually a committee of award, consisting of three experts, who shall carefully examine the essays offered for competition, and if any one shall be found worthy of the prize as a substantial contribution to medical knowledge to recommend the same to the Association.

(d.) All essays placed by their authors for competition shall be in the hands of the chairman of the respective committees of award on or before the first day of January preceding the meeting of the Association at which the reports of the committee are required to be made.

(e.) All prize essays are considered as the property of the Association.

(f.) The names of the authors of the competing essays shall be kept secret from the committees by such means as the latter may provide.

(g.) Membership in either of the two committees shall not declare from membership in the other; nor shall membership in the committee of selection exclude a member from the privilege of offering a competitive essay.

IN THE SECTIONS.

Section of Practice of Medicine, Materia Medica, and Physiology. Dr. H. R. Hopkins, of Buffalo, N. Y., read a paper on Sphygmograms and Notes of Autopsies, in which he gave the results of a number of cases where the diagnosis had been aided by a modification of Pond's sphygmograph.

Dr. Robt. N. Taylor, of New York, read an essay On the Use of Chrysophanic Acid in the Treatment of Skin Disease. The manner of using this remedy was by combining it with simple ointment (gr. x. to $\mathfrak{z}\text{i}$.), which in certain skin diseases is a specific, especially those of a scaly nature. Sycosis, ringworm of the body, and the papular or scaly syphilides are each benefited, but in psoriasis it has achieved its best results.

A paper to be read by Dr. J. Solis Cohen for W. T. Gadbury, of Yazoo City on Artificial Inflation as a Remedial Agent in Diseases of the Lungs, was read by title.

Dr. William Pepper presented a further contribution to the local treatment of pulmonary cavities, in which he called attention to the benefit of injections directly into vomica. In one case, after forty-eight injections inside of a period of fourteen months, the cavity became obliterated. The patient died subsequently of Bright's disease, when the lungs were examined, with the above results. Seventeen other cases were referred to, in which two hundred and ninety-one injections had been made, but without as striking results as in the first case. Lugol's solution (\mathfrak{M} x. to $\mathfrak{z}\text{i}$. to $\mathfrak{z}\text{i}$. water) and carbolic acid were used, through an extra large hypodermic syringe.

In the discussion following the paper Dr. Pepper said that very few cavities ever heal spontaneously; and the supposed cicatrices of such healed cavities are in reality areas of exudation. He said that he would hesitate about recommending this procedure for general adoption, as he did not think its value was yet entirely established. Dr. Bennett, Dr. Wilson, and others said that they regarded the constitutional treatment as more important than any local treatment.

The Treatment of Scrofulous Diseases of the Skin was the title of a paper read by Dr. John V. Shoemaker, in which he extolled the effects of chlorate of potash given in doses of two to four grains four times a day; and stated that he believed it to be the only effective remedy in many cases of scrofuloderma. The views of the author were opposed by Dr. Ulrich, of Pennsylvania, Drs. Taylor and L. Duncan Bulkley, of New York, and Dr. Sherwood, of Brooklyn.

A paper was next presented by Dr. J. R. Uhler, of Baltimore, on Restorative Remedies, who exhibited specimens of cod-liver oil with bread, cod-liver oil in cheese, several preparations of malt extract, and preparations of pepsine. For the preservation of pepsine he had devised a process in which the fresh gastric mucous membrane was cooled with gypsum, and this, when it became hardened, was pulled off and ground up, ready to be dispensed to any one who would take it, or sold to any one who would buy it.

Section II. On Surgery, etc. The subject of puncture of the joints, recommended yesterday by Dr. Pancoast, was made the subject of general discussion, in which early aspiration was advised. Dr. Pancoast, in reply to a criticism, repeated the statement that the value of extension in treating articular affections is explained by the relief it affords the inflamed synovial membrane.

Dr. James L. Little, of New York, presented a paper on Compound Complicated Hare-Lip, with three cases in which the "inter-maxillary bone" was distinct from the superior maxilla, and projected. Hard and soft palates were both cleft. Several partial operations were required, before the complete result was obtained. These three cases were brothers; in the same family five other children, all girls, exhibited no such malformation. Photographs and casts were shown, demonstrating the results of operation.

Dr. Atlee, of Lancaster, Pa., among other cases in his own practice spoke of one family which contained seventeen members afflicted with hare-lip. Early operation is advisable. Dr. Sayre, of New York, said that he had operated upon a child only four hours old; and Dr. Hamilton, of New York, said that he had operated as early as twelve hours after birth. The best time to operate, according to Dr. Sayre, was before the lips were actively occupied in suckling.

Dr. D. H. Goodwillie, of New York, exhibited a series of models of an abnormal position of the inferior turbinated bones; and spoke of the influence exerted by the erectile (?) tissue covering these bones, in the production of disease.

A paper on Torticollis cured by open division of the sternal and clavicular origins of the sterno-cleido-mastoid muscle, followed by elastic traction, was read by title by Dr. A. C. Post, of New York; as was also one by Dr. Jos. C. Hutchison, of Brooklyn, describing a New Ether Inhaler, and a New Form of Transfusion Apparatus.

Dr. Goodwillie exhibited an apparatus for the administration of laughing-gas mixed with air.

Drs. DeForrest Willard and E. O. Shakespeare, of Philadelphia, presented a paper on Hip-Joint Disease, accompanied by microscopic sections of the parts taken from a case of death in the early stage of the disease. Dr. Willard's splint, made upon a plaster-cast model of the limb, was also exhibited.

Dr. John B. Roberts, of Philadelphia, read a paper giving the history and statistics of the operation of tapping the pericardial sac, in which he stated that the canula might be left *in situ*, and the sac washed out with antiseptic solutions.

This paper was followed by one from Dr. C. A. Leale, of New York, upon thoracentesis, which advocated the operation and urged its more frequent performance.

Dr. Robert F. Weir, of New York, in a clinical paper upon Cystotomy for Cystitis in the Male gave the results of forty-seven cases thus operated upon, the statistics of which had been collected by the lecturer. He recommended a free incision into the bladder by the lateral perineal incision, and that the wound should be kept open as long as possible by the frequent introduction of a glass tube. After ten days the tube can generally be permanently allowed to remain. In senile cystitis he advised the removal at the time of the operation, of part of the hypertrophied prostate gland.

Dr. Gouley, in discussing the paper, said that no patient would be relieved by the operation unless a free division of the urethro-vesical orifice had been secured.

An important resolution was here offered by Dr. Dawson, of Ohio, that a committee be appointed to report what steps it would be necessary to take, in order to permit members to publish their papers, either in abstract or entire, before the appearance of the annual

volume of Transactions. This resolution was adopted and a committee of three appointed.

Dr. Laurence Turnbull, of Philadelphia, read a paper on Skin Grafting. Dr. Burchard, of New York, reported a case where five hundred grafts had been taken from an amputated thigh and placed upon an ulcerated breast, with good results. He said that to Van Wagenen belongs the credit of originally suggesting this procedure.

A paper by Dr. M. Bass, of Philadelphia, describing a new inhaler, was read by title.

Dr. Wm. A. Byrd reported a case of intestinal obstruction, where laparotomy and colotomy were successfully performed.

Dr. Gouley agreed with the lecturer concerning the danger of delay, but sufficient time should be taken to confirm the diagnosis. He insisted that laparotomy, to be successful, must be performed before peritonitis has set in. Dr. Jewett, of Massachusetts, strongly recommended the introduction of a long rubber tube and large warm water injections previous to operation. Dr. Weist, of Indiana, said that in several cases in his experience the let-alone policy had been very successful.

A new apparatus for the treatment of club-foot and other deformities was next exhibited by Dr. Doyle, of Syracuse, N. Y.

Section III. On Obstetrics and Diseases of Women. The Management of the Third Stage of Abortion, with Retention of Placenta and Membranes, was the subject of a communication from Dr. J. T. Johnson, of Washington, in which he emphasized the fact that the patient was not free from danger until the uterus had been entirely emptied.

Dr. Morris, of Baltimore, Dr. S. T. Hubbard, of New York, and Dr. Trenholme, of Montreal, discouraged middlemen interference with the curette, and advised the tampon to check the hemorrhage, and carbolized-water injections. Many cases of abortion being caused by uterine tumors, which the curette cannot remove, there is little need of operative procedure under ordinary circumstances. The opposite opinion was expressed by Dr. Marey, of Massachusetts, and Dr. Hanks, of New York, who urged prompt dilatation of the cervix and removal of the portions of placenta or membranes.

Gastro-Hysterectomy: Being Remarks on and Exhibition of a Full-Term Uterus removed by Laparotomy, was the title of a paper by Dr. I. E. Taylor, of New York. The patient had been delivered five years before by laparotomy, on account of a kyphotic pelvis. In the present operation two ligatures had been placed around the cervix, after delivery of the child by Cesarean section, and the uterus removed by cutting between the ligatures. On the twenty-seventh day, after an attack of phlegmasia alba dolens, the patient died of cardiac thrombosis. Out of fifty cases now on record, twenty-one had recovered where gastro-hysterectomy had been performed in cases with deformed pelvis.

Dr. H. O. Marey presented an elastic uterine dilator, which could also be used for a repositr in cases with inverted uterus.

Dr. T. G. Thomas, of New York, read a paper which he had entitled Clinical Contributions to the Subject of Removal of the Uterus in Whole or in Part by the Extirpation of Tumors connected with that Organ. The paper was based upon seven cases (five

of entire ablation, one of the fundus, and one of the whole body): four of these recovered; the three fatal cases were all operated upon for large solid tumors. A tumor susceptible of diminution in size by tapping is not so dangerous, therefore, for operation as one which, being solid, involves the necessity for a long abdominal incision. In this connection Dr. Gilman Kimball's cases of extirpation of the uterus were referred to, in which only five deaths occurred in thirteen cases.

Section of Diseases of Children. A temporary section was organized for the consideration of pediatric medicine. On motion of Dr. A. Jacobi, of New York, Dr. S. C. Busey, of Washington, was elected chairman, and Dr. F. Woodbury, of Philadelphia, secretary.

Dr. A. Jacobi presented, in a very interesting address, the claims of the pathology of children for distinct consideration, and concluded by offering an amendment to the by-laws of the American Medical Association, establishing a permanent section on diseases of children. This resolution was adopted, and directed to be presented at the general session.

Dr. S. C. Busey read a paper on Bright's Disease in Children caused by Malaria, and cited three cases in which the malarial cachexia was followed by renal disease with the usual symptoms. He also reviewed the therapeutics of this disorder.

Dr. Jacobi suggested that malaria might cause nephritis in two ways: in the first place, from debility of the circulation leading to thrombosis and inflammation; and, secondly, the destruction of the red-blood cells and presence of pyriant may lead to embolism. Griesinger and Rosenstein both speak of kidney disease caused by malaria.

A Case of Congenital Lymphæctasia was reported by Dr. James L. Green, of Elizabeth, N. J., in which injections of iodine appeared to have some effect in reducing one of the large tumors.

Section IV. On State Medicine, etc. Resolutions in which the present centralized and imperial National Board of Health was condemned, and Congress petitioned to abolish it and to have another board substituted, having been referred by the general session to this section for consideration, it was resolved that the passage of such a bill would be impracticable and unadvisable, and also that the present national board is satisfactory in its working and organization.

The Temperature of Living-Rooms was read by the secretary, for Dr. R. C. Kozlie, of Michigan.

Dr. A. C. Carroll, of New York, read an essay upon The Personal Factor in the Ætiology of Preventable Disease, in which the susceptibility of the patient was considered.

Hot-Air Bathing as a Means of promoting Health and preventing Disease was considered in a paper by Dr. E. C. Angell.

Microscopical sections from cases of disease of the brain and spinal cord were presented by Drs. Charles K. Mills and Carl Seiler, of Philadelphia, including posterior spinal sclerosis, hydrocephalus, two of epilepsy, and one from hydrophobia.

Section V. On Ophthalmology, Otology, and Laryngology. Dr. W. H. Daly described the Therapeutic Value of the Galvano Cautery in Diseases of the Naso-Pharynx, in a number of cases, to destroy adenoid growths, etc.

A very interesting scientific dissertation by Dr. Knapp, of New York, illustrated by models, to dem-

onstrate the principles of The Refraction of Light by Asymmetrical Surfaces, particularly considered the subject of the physics of astigmatism. Dr. Knapp does not correct an astigmatism less than $\frac{1}{2}$, as the physiological astigmatism is from $\frac{1}{6}$ to $\frac{1}{10}$.

Dr. S. S. Jones, of Chicago, volunteered a paper on the Introduction of Liquids into the Eustachian Tubes and Middle Ear, in which the injection, without force, of weak saline solutions (at 60°) in dry, chronic non-suppurative inflammation of the middle ear was highly recommended. Considerable discussion was excited by this paper, Dr. Knapp opposing the procedure, and Dr. Reynolds limiting it to chronic perforation of the membrana tympani. Dr. Holcombe, of New York, said that he had abandoned such injections, but still uses iodine vapor.

Dr. E. C. Gruening volunteered a paper on Wickersheimer's preservative fluid for animal substances, which was bought and published by the Prussian government, as follows: To three thousand parts of boiling water put one hundred parts of alum, twenty-five parts of common salt, twelve parts of saltpetre, sixty parts of carbonate of potash, ten parts of arsenious acid. Cool and filter, and add to ten parts of this solution four parts of glycerin and one part of methylic alcohol. Specimens were presented which had been preserved in this fluid, notably some eyes, which had even retained the transparency of the cornea, and appeared fresh and not shrunken.

ENTERTAINMENT.

In the evening the delegates attended a representation of Othello at Booth's Theatre.

THIRD DAY: GENERAL SESSION.

The report of the Committee on Nominations was received, which was unanimously adopted, as follows:

President, Dr. John T. Hodgen, of St. Louis, Mo. First Vice-President, Dr. W. H. Anderson, Alabama; Second Vice-President, Dr. Levi G. Hill, Alabama; Third Vice-President, Dr. Henry T. Holton, Vermont; Fourth Vice-President, Dr. Carpenter, Oregon. Permanent Secretary, Dr. William B. Atkinson, Philadelphia, Pa.; Treasurer, Dr. Robley J. Dunglison, Philadelphia, Pa.; Librarian, Dr. William Lee, Washington, D. C.

Judicial Council: Drs. J. K. Bartlett, Missouri; F. Staples, Minnesota; D. R. Wallace, Texas; J. G. Thomas, Georgia; J. S. Billings, United States Army, Washington, D. C.; J. H. Warren, Massachusetts; A. T. T. Woodward, Vermont.

Section of Medicine: President, Dr. Wm. Pepper, Philadelphia; Secretary, Dr. T. A. Ashby, Maryland.

Section of Surgery: President, Dr. Hunter McGuire, Virginia; Secretary, Dr. Duncan A. Eve, Tennessee.

Section of Medical Jurisprudence: President, Dr. J. T. Reeve, Wisconsin; Secretary, Dr. R. G. Jennings, Arkansas.

Section of Obstetrics: President, Dr. Jas. R. Chadwick, Massachusetts; Secretary, Dr. Joseph Taber Johnson, District of Columbia.

Section of Ophthalmology: President, Dr. D. S. Reynolds, Kentucky; Secretary, Dr. S. M. Barnett, District of Columbia.

Section of Diseases of Children: President, Dr. A. Jacobi, New York city; Secretary, Dr. William Bradford.

Committee on Prize Essay: S. E. Chaillé, New Orleans, La.; J. L. Cabell, Richmond, Va.; A. N. Bell, Garden City, N. Y.

The next meeting to be held in Richmond, Va., on the first Tue-day in May, 1881. Assistant Secretary, Dr. J. L. Cabell, Va.

Dr. Denison, of Colorado, being unable to attend and fill the duties of chairman of section on Practical Medicine, his resignation was accepted.

Dr. Bronson, of Massachusetts, offered the following, which was adopted:—

Whereas, The published proceedings of various sections of this Association does not receive the practical expression desired, and does not represent the labors of its members; and

Whereas, The members of the Association have long felt that the present mode of introducing the Transactions to the profession has been unsatisfactory to all concerned in the advancement of medical science; therefore, be it

Resolved, That a committee of five be appointed by the chair to report at the next session regarding the propriety of formulating all the proceedings in journalistic form, as recommended by the president in his annual address.

The committee is constituted as follows: Drs. W. W. Dawson, Ohio; J. R. Bronson, Massachusetts; W. H. Pancoast, Pennsylvania; N. C. Husted, New York; J. S. Green, New Jersey.

The report on National Sanitaria was read by title, being presented by Prof. H. I. Bowditch, of Massachusetts, and referred to section on State Medicine.

Dr. J. C. Billings reported upon the Catalogue of the National Library, that Congress had made provisions for the publication of the volumes, the first of which will appear in July, 1880, and the second in 1881.

The following amendments to the constitution, proposed by John H. Rauch, were adopted: Art. II., second paragraph, after "Army and Navy," insert "and the Marine Hospital Service of the United States."

Art. II., fourth paragraph, at the end, insert "the Marine Hospital Service of the United States shall be entitled to one delegate."

Dr. S. C. Bussey offered an amendment to the by-laws, making provision for a new section, to be denominated Section VI., On Diseases of Children. This was also adopted.

The report of the Metric Executive Committee was read by the secretary, who moved its adoption. After a warm discussion it was adopted as follows:—

The American Medical Association (1) recommends the teaching and practice of the metric system in medical colleges, clinics, dispensaries, etc.;

(2) Charge its Metric Executive Committee with the duty to report annually on the above institutions which teach, and those which do not teach, the metric system;

(3) Authorizes said committee to enter in communication with the Metric Committee of the British Medical Association, in order to concert such plans as may render the use of the metric system simultaneous and uniform in both countries.

Dr. Reynolds, of Louisville, offered a resolution requesting Congress to favor the experiment of building a refrigerating ship, which was, on motion, laid upon the table.

Dr. W. M. Beach, of Ohio, moved that the president appoint a committee to secure for the medical staff of the army and navy a social position equal with that of similar grades in other departments of the service. Carried.

The Judicial Council reported that the Hannibal Medical Society of Missouri is not entitled to representation in the American Medical Association, because it is not in affiliation with its own State Medical Society.

Dr. James F. Hibberd, chairman of the section on State Medicine, in presenting his annual address referred with commendation to the increased interest shown in this department of medicine. In taking up special subjects, he condemned the barbarous method of hanging criminals, and recommended prussic acid, electricity, or other equally painless methods; he also referred to the late investigations in brain function, and their relation to psychology. Proceeding to the care of the insane, he spoke of the duties of the state towards this class; and of intemperance and heredity as a cause of crime.

The report of the Committee on Necrology was read by the chairman, Dr. J. M. Toner, and referred to the Committee on Publication.

Delegates were appointed as follows: To the Canada Medical Association, Drs. C. N. Brush, Buffalo, N. Y.; Jas. R. Leaming, N. Y.; D. H. Goodwillie, N. Y.; Wm. Brodie, Detroit, Mich.; W. B. Ulrich, Chester, Pa. To European medical societies: Drs. R. Beverley Cole, San Francisco, Cal.; Benjamin Lee, Philadelphia, M. A. Pullen, New York, and L. D. Bulkley, New York.

The report of the librarian was received and entered upon the minutes; it stated that there was 3258 volumes. Two hundred dollars were appropriated for the library.

The following committee was appointed to consider the recommendations contained in the president's address. Drs. Chaillé, La.; S. D. Gross, Pa.; J. S. Weatherly, Ala.; J. R. Bronson, Mass.; and W. R. Gillette, N. Y., to report in 1881.

(To be concluded.)

CONNECTICUT MEDICAL SOCIETY: EIGHTY-NINTH ANNUAL CONVENTION.

THE president and Fellows of the Connecticut Medical Society held their eighty-ninth annual convention in the common council chamber, City Hall, New Haven, Wednesday afternoon, May 26th, commencing at three o'clock. The Fellows correspond very nearly to the councilors of the Massachusetts Society, and transact the business of the society for the most part. Any member, however, who has once been a Fellow has all the privileges of the floor for the introduction of business or its discussion, but not for voting. The attendance was not large, but thirty out of a possible fifty-two. For some reason the sessions at Hartford call out a much larger attendance. Last year there were forty-eight Fellows, and about a hundred and fifty on the second day, when the general exercises are held, while here there were at no time a hundred present. The session was, however, an extremely interesting one. All parts of the State were represented, and the papers were valuable and elicited much more than the usual amount of discussion. Owing to the

recent recovery of the president from a severe attack of basilar meningitis, he gave no address, except the customary *résumé* of matters which required the attention of the convention. This contained a reference to the important sanitary relations the society bore the State, and pointed to highly valuable work the society had done for the State in the past; a part of this work being the shaping of sanitary legislation for the protection of the powerless and the development of the weak-minded, and another part being the origin and promotion of legislation regarding the collection of vital statistics. No foreign interference was needed until its incompetency was clearly demonstrated. The State Board of Health was complimented, and the gratifying progress of sanitary science referred to. Every safeguard should be placed around the sale of poison, so as to prevent its disposal for criminal or suicidal purposes. Preventive medicines, like conservative surgery, will be considered in the near future as affording the highest possible illustration of professional skill. Allusion was made to the careless manner in which records of vital statistics were kept in certain towns. "The present status of medical expert testimony is a reproach to the profession, and it is high time some steps were taken to remedy the most glaring evils connected with this subject. Either consciously or unconsciously the expert becomes the medical advocate of the person by whom he is called, instead of an impartial witness of the facts as best known to medical jurisprudence, and it is to be feared that too often the fee is made contingent upon the amount of damages secured through the testimony of the expert. Men are too often summoned as experts who have no special fitness, either by position or acquirements, to pronounce upon facts that require the devotion of a life work to comprehend and elucidate, much more to decide *ex cathedra*."

The address in its concluding pages asked attention to the "indiscriminate practice of medicine by the ignorant and unqualified," terms applied to impostors and uneducated persons, in regard to which a bill was before a recent legislative body, and which it was thought would have passed had it been suitably amended; and then paid a tribute to the departed members of the society for the past year.—Drs. H. M. Knight of the School for Imbeciles, Lakeville, ex-President B. H. Catlin of Meriden, and A. B. Haile of Norwich. The address was ordered incorporated in the proceedings of the society.

On motion of Dr. Russell, of Hartford, that portion of the president's address relating to expert medical testimony was referred to a committee of three, to be appointed by the chair, and Drs. G. W. Russell of Hartford, S. G. Hubbard of New Haven, and William Denning of Litchfield were appointed to report to the next convention what measures should be recommended to the legislature to remove the reproach now resting upon the medical profession and to advance the cause of justice in the courts.

Professor L. J. Sanford moved a similar committee on new and enlarged powers to be given the State Board of Health, with reference to preserving the records of vital statistics in the several towns in a proper manner. The motion was carried, and Drs. M. C. White of New Haven, W. A. M. Wainwright of Hartford, and A. M. Shaw of Middletown, were appointed.

The next business in order was the report of committees appointed last year on recommendations in

President Carleton's paper. The committee on the metric system reported a series of resolutions recommending that it be adopted by the society, required in all essays hereafter read at its conventions, used in the medical department of Yale College, and recommended for all hospitals and dispensaries; and that physicians should familiarize themselves with it and assist druggists to understand its practical use. The last resolution alone was accepted; the others were rejected. It was urged that physicians were not yet familiar enough with the metric system to authorize any such action by this society; for that reason the last resolution was passed encouraging its study by physicians. The report elicited considerable discussion on both sides, and the reasons for its acceptance were very fairly presented; theoretically, the system found many friends but these were not ready yet to advocate any compulsory use.

The committee on the medical examiner system of Massachusetts and its adaptability and desirability for Connecticut reported unanimously in favor of the system as superior to the antiquated coroner system, but on consulting the records of the courts there did not appear to have been any glaring instances of abuse in this State, our population being considerably different from that of Massachusetts (not so many large manufacturing cities). Moreover, we never had been accustomed to more than one coroner in a city, however large, with perhaps one assistant, while in the towns the first selectman or a justice of the peace acted in that capacity. On consultation with some of the most eminent lawyers in the State, their opinion was invariably that the system, although an admirable one, was not required in this State, and could not be engrafted on to our legal system without very many and great changes.

Dr. A. N. Bell, of Garden City, L. I., Dr. E. C. Seguin, of New York, were elected honorary members of the Connecticut Medical Society. These names were proposed last year, but by rule lie over one year for action. Dr. Bell has been identified with the State in many ways, receiving the degree of A. M. from Trinity College in 1855. Dr. Seguin was connected for several years with the State Institution for the Insane, at Middletown. Both were elected by unanimous vote.

The treasurer's report showed a very prosperous condition. Less than fifty dollars of the tax laid in 1879 remained uncollected,—an unprecedented condition of affairs. The most backward portions of the State, and those almost invariably in arrears heretofore, now presented almost a clean bill. This was due to the energy and skill of Drs. F. M. Wilson, of Bridgeport, and C. W. Gaylord, of Branford, clerks in their respective counties. The prosperity of the society depends to a very great degree upon the county clerks, who are the only executive officers in these societies which together make up the state society. It is to be hoped that these gentlemen will long be retained in the offices they honor.

Last year a series of resolutions was introduced, requesting that a committee be appointed to urge upon the legislature the appointment of commissioners in lunacy, and defining their power; also, that a change should be made in the law which requires the sworn statement of one reputable physician only for the commitment of any person to a lunatic asylum. The whole matter was, however, referred to a committee

to report to this convention. The committee reported as follows:—

Whereas, we consider that our information upon the questions involved in the resolutions referred to us is not sufficiently extensive to enable us to recommend decided action at present, we submit the following resolution:—

Resolved, That a committee of three, conversant with the history of insanity, should be appointed by the state convention to investigate the subject of lunacy commissions in other States, as well as in foreign countries:—their history, aims, and results,—for the information of the next annual convention.

MOSES C. WHITE,
N. NICKERSON,
GORDON W. RUSSELL,
C. W. CHAMBERLAIN,
C. A. LANDSLY,

Committee.

The report was accepted, and the president appointed as members of this committee A. M. Shew, superintendent of the State Asylum for the Insane, Middletown; H. P. Stearns, superintendent of Retreat for Insane, Hartford; and D. A. Cleveland, Middletown.

The following officers were elected for the ensuing year: President, G. L. Platt, Waterbury; Vice-President, Wm. Deming, Litchfield; Treasurer, F. D. Edgerton, Middletown; Secretary, C. W. Chamberlain, Hartford; Committee on Matters of Professional Interest, W. A. M. Wainwright, L. S. Wilcox, Hartford, L. W. Bradley, New Haven; Delegates to Massachusetts Medical Society, N. Nickerson, Meriden, F. M. Wilson, Bridgeport.

After the usual routine business, the convention adjourned.

SECOND DAY.

The society met at half past nine A. M., at the same place, the president, A. R. Goodrich, in the chair. The first business in order was the reading of the secretary's report. This showed a year of marked prosperity, in spite of a loss of fifteen by death, removals, and otherwise. There was a net gain of twenty, thirty-five new members, ten deaths. The society now numbers 440. There has been an annual death-rate of ten for the last five years; but in spite of that, there has been during this time a gain of sixty-five in membership. Judging by appearances, this time-honored society has never been so flourishing as at present.

Dr. Wainwright followed with a short report, as the year had been an unusually healthy one, with no epidemics, general or localized, but little material for a report was at hand. Several cases of interest from the various counties were referred to the committee of publication.

Dr. Brown presented a patient, a boy of twelve, with extensive burn from hip to knee, where skin grafting had been tried. Two thousand grafts had been used, the greater portion successfully. Healing resulted without cicatrization or contraction. There was at the centre an opportunity to see how healing spread from the small autaneous graft.

Dr. J. L. Miller, of Sheffield, Mass., a delegate from the Massachusetts Medical Society, was presented to the society, and in a brief address gave the greetings and kind wishes of the society he represented.

Dr. Frank H. Hamilton, of New York, an honorary member of the society, was then introduced by Dr. St. John, and on invitation of the president presented a short address treating briefly of Colles's fracture. He advocated light dressings; one splint underneath, so padded that there was nothing directly underneath the fragments; bandaging loosely, leaving the hand entirely free; and where the patient could be trusted removing all dressings at the end of the third week.

A telegram was read from Dr. J. M. Sims, regretting his inability to be present, and conveying his kind wishes.

Dr. Carmalt, professor of ophthalmology at Yale, presented, with full descriptions, a perimeter which he had devised for measuring the limits of the visual field; it was to take the place of the more expensive instruments, and won universal approbation at the convention of the American Ophthalmological Society at Newport, where it was exhibited.

The annual dissertation was then given by Professor Carmalt, on *Some Limits in the Use of the Ophthalmoscope*. The design was to save the instrument from its injudicious friends, who were claiming too much for it, so as to throw discredit upon its just claims. While of inestimable value in the diagnosis of ocular troubles, it could not enable us to diagnosticate the intra-cranial circulation, whether congested or the reverse, nor to determine cerebral disease.

Dr. H. P. Stearns, of Hartford, read a very interesting and instructive essay on the *Border Land between Sanity and Insanity*.

Dr. J. B. Kent, of Putnam, followed with an essay on *Functional Derangements of the Nervous System*.

Dr. John P. C. Foster read a very interesting essay on *The Hereditary Transmission of Syphilis*, in which he presented a *résumé* of the modern views on that subject, among other points claiming that the child might be inoculated without the mother becoming syphilitic during gestation.

Dr. C. J. Fox, of Willimantic, read a paper on *Chrysophanic Acid in Skin Disease*, advocating its use in psoriasis, eczema, and herpes.

Many other interesting papers would have been read had time permitted.

—The *Medical Times and Gazette* tells the following story: A poor Hungarian widow, living in a garret at Limehouse with her deaf and dumb son, was overtaken by hard times, and fell ill. Some kind people went to her aid. They found the room wretchedly furnished, but covered all over with colored prints and engravings. Looking over these, a hundred-pound note was discovered pasted between a cut from the *Illustrated London News* and a business card. The discoverers doubted their eyes, and the doctor, who had been sent for, coming in at the time, was made aware of the circumstance. An attempt to detach the engraving from the wainscot failed, and by direction of the medical man the piece of panel was cut out, taken to the Bank of England, and cashed, when the doctor explained that the proceeds would be lodged to the credit of the old lady. It seems that she had picked up the note two years ago, and seeing in it only a picture fixed it on the wall of her room, where it remained an unsuspected treasure.

Medical and Surgical Journal.

THURSDAY, JUNE 10, 1880.

A Journal of Medicine, Surgery, and Allied Sciences, published weekly by HOUGHTON, MIFFLIN AND COMPANY, Boston. Price, 15 cents a number; \$5.00 a year, including postage.

All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.

Remittances by mail should be sent by money-order, draft, or registered letter to HOUGHTON, MIFFLIN AND COMPANY, BOSTON, MASS.

ANNUAL MEETINGS.

THE return of June brings the recurring annual meetings of national associations and state societies, with a pressure upon our columns to which, although greatly extended, they are hardly adequate, and other matters yield to this summing up, as it were, of the year's medical work; but readers have enjoyed very full accounts of the meeting of the National Association in New York, which are nearly completed in the present issue. The thirty-first annual meeting of this association has been in almost every particular a very successful one, and reflects much credit upon its manager. The difficulties attendant upon a plethora of papers, many of doubtful value, and of much unprofitable discussion have not been less apparent than at other times. These drawbacks, however, are inherent to the present organization of the association, and to any large body which meets to talk. There is promise for the future in their recognition, and in the fact that suggestions for the correction of such disadvantages are made and temperately considered. The proposal of the president, Dr. Sayre, that the association establish its own journal, in which its transactions should be promptly published, instead of keeping them for a bulky and tardy volume, was not favorably reported upon by the committee on state medical societies and medical journals, to which it was referred. The report, prepared by Dr. S. D. Gross, of Philadelphia, expresses the opinion that the time for the establishment of such a weekly journal as was recommended in the address has not yet arrived. The history of the *British Medical Journal* in its connection with the British Medical Association is certainly very striking, and it is probable that at no distant date the desirability of some similar arrangement for the publication of its transactions and the increase of its influence and usefulness will be generally recognized by the members of the American Association. The entertainments offered to those attending the meeting were of that varied and extensive character which hardly another city in the country except New York could afford, and could have been secured there only by a very energetic and enthusiastic committee of arrangements.

Between Booth's lagoon and an excursion around the harbor, with Coney Island included, there was a wide range of choice for individual tastes, and he must have been a dull member who could not find much to amuse and instruct the mind. The bodily wants seem to have been nowhere neglected.

This week the quieter and simpler, but to us no less

interesting and important, transactions and festivities of the annual meeting of the Massachusetts Medical Society claim attention. The programme of papers and proceedings is a strong indication of an unusually successful meeting, and the composition of the committee of arrangements, together with the experience of the anniversary chairman, give every security that the closing exercises in Music Hall will be satisfactorily conducted. Referring again to the suggestion of a journal in connection with the American Medical Association, it may not be amiss to remind members of our state society, and especially those in the country, of the possible advantages of a more cordial support of their home journal.

The society will learn, among other things, that England, not content with taking our wheat and beef, has carried off our Boylston prize this year. It is true, she has paid for it in a very excellent essay; but exportation, as well as importation, may be carried much too far, and we hope some enterprising member of the society will make it his duty to restore the balance of trade.

Among other losses which the profession in Massachusetts has suffered during the year is that of two physicians, lately deceased, whose ripe years and faithful services demand the respect and will repay the attention of younger men. Dr. Edward Flint, of Leicester, recently died, aged ninety and one half years. He was a native of the town, and rarely left it, except for a brief visit to Boston or Worcester. He withdrew from active practice only a few years ago. His father, Dr. Austin Flint, preceded him in practice in the same town, and was a surgeon in the revolutionary army. His grandfather was also a doctor.

Dr. George Choate, for many years a successful practitioner in Salem, has also been taken away at the age of eighty. His good example and sterling qualities have borne fruit in sons distinguished both in medicine and the law.

These two men were both types of all that was sound and good and reliable in the old-time New England practitioner. The memories of such should be cherished as their presence among us becomes more and more rare. It may well be questioned whether the increased extent of knowledge and of facilities for its acquisition are not sometimes inimical to that steadiness of character so often found in preceding generations.

MEDICAL NOTES.

—The New Hampshire Medical Society will hold its ninetieth annual meeting in Phenix Hall, Concord, on June 15th and 16th.

—At the monthly meeting of the State Board of Health, Lunacy, and Charity, held June 5th, an order was passed requiring Messrs. Clark, Gleason, Fiske, Travis, Pebbles, and Johnson, of the town of Natick, to desist and cease from further pollution of Pegan Brook, a tributary of Lake Cochituate, the water supply of Boston, on and after July 15th. This is the first case which has come before the board under the

recent law forbidding the pollution of water supplies, and the decision given must have a wide influence in purifying streams and ponds used for domestic purposes throughout the State.

— A case of varioloid, papular stage, was recently discovered by Dr. F. Winsor, in Winchester, the patient, a boy of eleven years, having come to New York with other English emigrants. There being a case of small-pox on board the steamer, the health officers vaccinated the passengers "by the hundred." It is stated that this boy was considered too feeble, in consequence of prolonged seasickness, to be vaccinated. He bears the scar of an early vaccination on his arm.

— The New York State Board of Health has organized by electing the following officers: president, Dr. E. M. Moore, of Rochester; secretary, Dr. Elisha Harris, of New York. The president is also the health officer of Rochester; the secretary is one of the best known sanitary organizers and publicists in the country. The personnel of the board is as follows: state commissioners for three years, Hon. Erastus Brooks, Staten Island, Elisha Harris, M. D., New York city, D. J. S. Delavan, Albany; commissioners "who," as the law provides, "must be members of existing city boards," E. M. Moore, M. D., Rochester, James G. Hunt, M. D., Utica, C. F. Chandler, M. D., New York city: ex-officio members, Dr. W. M. Smith, health officer of the port of New York, Hamilton Ward, Esq., attorney-general, James S. Gardiner, Esq., director of the state survey. The head-quarters of the board will be in Albany.

— The *Medical and Surgical Reporter* publishes this interesting item:—

At a late meeting of the London Obstetrical Society a paper, by Dr. Robert P. Harris (Philadelphia), entitled *A Complete and Authoritative Refutation of the Marvelous Account given by Professor Claude M. Gardien, of Paris, in 1816, to the Effect that the Princess Pauline de Schwartzberg was delivered of a Living Fetus some Hours after she was burned to Death*, was read. The author said the story told by Professor Gardien was that the princess perished from the effects of burns received at a fête given in the house of the Austrian ambassador, her brother-in-law, on July 1, 1810; that she was pregnant, and the infant was found alive, although she was not opened until the day after the accident. From research among contemporary authorities the author found that the ball was given in a large temporary wooden building, and the fire broke out soon after dancing commenced. The princess escaped with others, but rushed back to seek for her daughter, and so perished. In the morning the disfigured remains were recognized as hers by a piece of gold jewelry. Madame Junot writes that "her body, with the exception of her bosom and part of one arm, was burned to a cinder." The *Court Journal* of July 3, 1810, states that the princess was *four months* pregnant. No mention is made of the case in the medical journals of the time. This story, therefore, which was repeated by Gardien in his third edition, quoted by

Veuplean, and has attained general notoriety, is absolutely without foundation.

— The *Boston Journal of Chemistry* says that George the Third had three physicians, whose names have been made the subject of rhyme in the following epigram, which lately appeared in the *London Medical Times and Gazette*:—

The King employed three doctors daily —
Willis, Heberden, and Baillie —
All exceedingly skilful men,
Baillie, Willis, and Heberden;
But doubtful which most sure to kill is,
Baillie, Heberden, or Willis.

— The June number of *The North American Review* contains Popular Fallacies about Russia, by E. W. Stoughton, ex-Minister to Russia; Divorees in New England, by Dr. Nathan Allen; McClellan's Last Service to the Republic, by George Ticknor Curtis; Has the Southern Pulpit Failed? by Rev. Dr. F. A. Shoup; Caste at West Point, by P. S. Michie, Professor of Philosophy at West Point; and Some Interesting Publications, by M. W. Hazeltine. This number closes the one hundred and thirtieth volume and sixty-fifth year of the *Review*. During the last few years this magazine has made a most remarkable advance in popular favor. Many of its numbers have passed through several editions, and its permanent circulation has increased more than sixfold.

NEW YORK.

— The New York Flower Charity has now resumed its work for the season, and on every Monday and Thursday until the first of November the ladies may be seen starting out from the head-quarters of the society, at the corner of Fourth Avenue and Twentieth Street, laden with their pleasant offerings to the suffering and destitute. Since the organization of the society more than a million bouquets have been distributed by it in the various hospitals and asylums, and among the sick poor in the tenement-houses.

— On the 6th of May — Ascension Day — the Ladies' Association of the House of Rest for Consumptives held their fifth annual reception at that excellent institution, which is situated at Tremont, on the Harlem Railroad. As one might suppose from the name, its object is to furnish such comforts and such freedom from the anxieties of life as would otherwise be quite impossible among the class of patients which it is designed to relieve; and the good work which it thus accomplishes is abundantly shown in those whose descent to the grave is deprived of much of its bitterness and suffering, in those whose lives are greatly prolonged by the kind care that they receive, and in those who through this instrumentality are restored once more to active usefulness in society. In order properly to carry out the work of the institution a new wing is necessary in the building, the cost of which will be about five thousand dollars.

— It is not often that a case of actual starvation takes place in a community like this, but such an instance was lately reported to the bureau of vital statistics by Dr. E. B. Daley, of Harlem. The patient was an Irishwoman, twenty-eight years of age, whose husband had been out of employment for a long time.

She was taken sick a couple of months before, and since that time had received neither proper medical treatment nor proper nourishment. Her children were also much emaciated when the case was discovered. There were three other families living in the same house.

PHILADELPHIA.

— Dr. Joseph W. Taylor, of Burlington, N. J., formerly a resident of this city, who died a short time ago, left a will which contained many public bequests, and under its provisions the residuary estate, amounting to nearly nine hundred thousand dollars, was confided to trustees for the purpose of building and endowing a college for the education of women. The trustees of this legacy have now received authority, by act of incorporation, to accept the trust. Dr. Taylor, during his life, purchased a tract of thirty acres near Bryn Mawr as a site for the projected college, and had laid the foundations of two of the principal buildings, which will now be rapidly pushed forward, and it is believed they will be ready for occupancy in 1883. The college will be under the control of the Orthodox Friends.

— The trustees of the State Hospital for the Insane at Norristown have elected Dr. Robert H. Chase, of Washington, D. C., as resident physician at a salary of \$2000. Dr. Chase was born in 1845, and received the degree of A. B. at Haverford College. He graduated in medicine at the University of Pennsylvania, and for several years held the position of first assistant physician at the Government Hospital for the Insane at Washington.

— In Philadelphia, on May 27th, the thermometer was 95° F. in the shade, a condition which has not been equaled in ten years. Several fatal cases of sunstroke have already been reported.

— A death from ethyl bromide occurred on the 26th inst. under the following circumstances: A young man suffering with stone in the bladder had been for several months in the Jefferson College Hospital, waiting to get into proper condition for operation. He had cystitis, though not to a high degree; there was also cough and emaciation, although no evidence of heart or kidney disease. His friends had become tired of the delay, and had decided upon removing him to his home, where he evidently would soon succumb. Under the circumstances Dr. Levis decided to give him his only chance for recovery, and to operate upon him in spite of his poor condition. Having everything ready for the operation, about a drachm of ethyl bromide was poured upon a cloth and held over the mouth and nose. The patient took a few inspirations, and then quietly stopped breathing, and died before lithotomy had commenced. Artificial respiration was unsuccessful. At the autopsy the lungs were found to be in an advanced state of pulmonary phthisis, and the bronchi were filled with mucus, forced into them during the attempts at artificial respiration. Nothing special was observed in the other organs, which were, however, given to the pathologist for a careful examination, and will hereafter be made the subject of a special report.

Disseclany.

ANNUAL MEETING OF THE MASSACHUSETTS MEDICAL SOCIETY.

THE ninety-ninth annual meeting of the Massachusetts Medical Society, held on Wednesday of this week, was preceded by the customary initial gathering on Tuesday, on which day the society was called to order by Vice-President David P. Smith promptly at twelve o'clock, in Horticultural Hall.

During the forenoon the Fellows were entertained at the Massachusetts General Hospital, City Hospital, Carney Hospital, and the Lying-In Hospital by operations, ward visits, and exhibition of patients. At the Massachusetts General, Dr. Porter excised a sarcomatous testicle; showed two cases of radical cure of hernia, which consisted in taking a portion of the sac, folding it upon itself, and stitching it into the ring by means of strong carbolized catgut sutures, thus causing it to act as a retentive plug; also exhibited a case of ununited fracture of the radius and ulna, which had been operated upon by the wire treatment after the Bigelow method, and a second case of fracture of both bones of the fore-arm, which were uniting by means of the same treatment.

At the City Hospital Dr. H. W. Williams operated on three cases of strabismus; Dr. Thorndike on a case of hemorrhoids; Dr. Charles D. Homan dissected an epithelioma from the left ala of the nose of a man; Dr. Gay showed a lip on which he had operated on an immense nevus, involving lower lip, chin, and cheek; Dr. Ingalls exhibited an ingeniously arranged ambulatory extension for a leg ulcerated on the point of the stump.

Immediately upon calling the preliminary meeting to order, Dr. Smith introduced the reader of the first paper of the programme for this day, Charles D. Hunking, M. D., of Haverhill. Subject, Pneumonitis. The essay was interesting, and was followed by a most wholesome discussion; many Fellows expressing their views, and asking questions with a readiness which greatly added to the interest of the occasion, and which promises to grow into a most attractive feature of the annual gathering.

The second paper, subject, Pyæmia of Doubtful Origin, apparently Spontaneous, was read by its author, Charles H. Cook, M. D., of Natick. This paper likewise elicited remarks.

The closing essay of the morning session, by Arthur T. Cabot, M. D., of Boston, had for its subject, Antiseptic Treatment of Empyema. It received and deserved close attention. The meeting adjourned at two o'clock P. M. At three o'clock the reading of papers was resumed. An essay on Edema of the Lungs, with illustrative cases, was read by Henry F. Borden, M. D., of Brockton.

Additional interest was imparted by charts and discussion to a paper on the Relation of Bacteria to Disease, by William F. Whitney, M. D., of Boston. The closing paper, on Ambulatory Treatment of Hip Disease, by Charles P. Putnam, M. D., of Boston, was illustrated by numerous cases, among them patients kindly shown by Dr. E. H. Bradford.

The meeting then adjourned.

During the afternoon the Warren Museum at the Harvard Medical Department, the Warren Museum

of Natural History, on Chestnut Street, Children's Hospital, and the Museum of the Natural History Society were visited by Fellows of the society.

The annual meeting of the councilors of the society was called to order in the hall of the Medical Library Building at seven o'clock by the president, Dr. Geo. H. Lyman.

The secretary, Dr. F. W. Goss, read the record of the last meeting and the names of new and deceased Fellows, the number of the latter being thirty-three.

The treasurer, Dr. F. W. Draper, then read his report, in which he stated that the invested funds of the society, \$31,420.17, remained as at the last meeting. Receipts for 1879, \$8136.89; expenditures, \$6892.94; balance to new account, \$1243.95. The treasurer stated that a safe had been procured and placed in the Library Building. It now protects all the valuable documents and archives of the society.

The reports of standing committees were next presented.

That of the auditing committee, Dr. Stedman, chairman, was read by Dr. Gerry. It announced that the treasurer's report was correct in all respects, and that the securities were safely deposited. Dr. Draper's report was then accepted.

The brief report of the committee on finance, Dr. Charles Homaus, chairman, was next read. It recommended that twelve hundred dollars of the surplus in the treasurer's hand be distributed among the several district societies; that legal means be adopted to secure the payment of dues from a delinquent Fellow, etc. The report was accepted, and the recommendations were affirmed.

Committee on memberships and resignations, Dr. J. Ayer, chairman, presented names of Fellows to be allowed to resign, of others to go upon the retired list, and of others who are to relinquish membership because of absence from the State and for non-payment of dues. Report accepted and recommendations affirmed.

The name of an expelled member was brought forward with a petition for restoration to membership. The committee had considered his case, and had no reason to see why expelled members should be restored to membership. They could merely recommend him to the censors and the regular course. The wish of the committee was to establish a precedent for future cases of a similar nature, and which are constantly recurring. The matter gave rise to considerable discussion. A Fellow from the Worcester Society said the member in question had been an eclectic, but had repented, and wished to be restored.

Dr. How, of Haverhill, asked whether the action of the society in expelling a member means anything. If so, how can such a man be readmitted?

The question being raised as to how the person under discussion had been expelled, the reply of the secretary was that he had been dismissed by the board of trial for non-ethical conduct, and that this procedure was confirmed by the society at large.

Dr. Martin, of Worcester, thought such action should be final.

Dr. Jewett said the petitioner was a near neighbor of his, and hoped he would be readmitted, but in the regular way, — through the censors.

Dr. How again remarked that he could not see how an expelled member could be readmitted except by vote of the whole society, and moved that the matter

be indefinitely postponed. The motion was seconded and voted upon in the affirmative.

The next report was that of the committee on publication, Dr. G. C. Shattuck, chairman. The committee have received only two prize essays, and voted that no dissertation fully worthy of the prize had been sent in. But while regretting the necessity of this decision, they deem the essay on *Infantile Digestion* and that on *Experiments on Iron and Digitalis* deserving of praise.

In regard to exchanging *Braithwaite's Retrospect* for the *Boston Medical and Surgical Journal*, Dr. Shattuck announced that circulars asking the wishes of the Fellows had been sent out. Eight hundred replies had been received. Of these two hundred and ninety-nine preferred the *JOURNAL*, four hundred and ninety-four chose *Braithwaite*, the remainder were indifferent. The committee therefore recommends that the change be not made.

The report of the committee on by-laws and district societies, Dr. Hosmer, chairman, was read and accepted. Likewise the report of the committee on the library, Dr. Wadsworth, chairman.

The report of the nominating committee was next presented by Dr. Fisk, chairman, who said that, appreciating the importance of the next annual meeting, and realizing that the society is one of the largest and oldest in the world, and that it has contributed to science and humanity as much as any other medical society, referring especially to the great gift of anesthesia, the committee felt that the coming annual meeting, as the centennial gathering of the society, should be characterized as much by oratory and social enjoyments as by scientific papers. They consequently thought the officers for the next year should be largely chosen from Boston Fellows, through whose efforts the occasion would undoubtedly be made more enjoyable than if the society were officered by members out of the city. The committee therefore unanimously nominated the following gentlemen, with the belief that they would enable us to have a centennial of which the Fellows would be proud:—

H. W. Williams, Boston, President.

Asa Millett, East Bridgewater, Vice-President.

F. W. Draper, Boston, Treasurer.

Charles W. Swan, Boston, Corresponding Secretary.

F. W. Goss, Roxbury, Recording Secretary.

David H. Hayden, Boston, Librarian.

The ballots gave eighty-three votes, eighty-one of which were for Dr. Williams, and two for Dr. D. H. Storer as president. The remainder of the ticket was unanimously elected.

Dr. Fisk then said that, although the nominating committee found no by-law authorizing them to appoint the orator and anniversary chairman, they thought it not best to depart from the usual custom, and therefore recommended—

Dr. J. Collins Warren as orator.

Dr. Henry J. Bigelow as anniversary chairman.

These gentlemen were unanimously elected.

Dr. Bigelow, not being present until a later period, resigned his office so soon as notified of his election. The nominating committee retired, and upon their return presented the name of Dr. J. C. White as their candidate for the office of anniversary chairman. Dr. White was elected with warm approval. The time and place of the next annual meeting were then appointed, namely, Boston, second Wednesday in June, 1881.

The president then announced the standing committees for 1880-81.

With the exception of Dr. E. H. Bradford, appointed on the committee of arrangements *vice* Dr. Robert Amory, and of Dr. R. H. Fitz on the committee to procure scientific papers, *vice* Dr. H. W. Williams (now president elect), these committees remain as they were for the previous year.

Petitions for the restoration of former Fellows were referred to the proper committees.

Dr. B. Joy Jeffries moved that the council recommend to the committee of arrangements for 1881 the consideration of the exhibition, at the next annual meeting, of such instruments as have been invented by Fellows or such as have been invented by others and modified by them. This is a custom at the annual meetings of the British Medical Association, and in no way interferes with our customary exhibit of surgical instruments. The motion was seconded, and received an affirmative vote.

Dr. Draper then presented a proposition from the publisher of *Braithwaite's Retrospect*, Mr. Townsend, of New York, to supply a retrospect of American medicine in place of the British publication at half rates. Seven hundred sample copies were presented to the Fellows.

Previous to the adjournment President Lyman gracefully introduced the president elect, Dr. Williams, who, in an impressive manner, thanked the council for this new expression of their kind feeling toward him.

By invitation of Dr. Lyman the councilors then adjourned to his house.

On Wednesday A. M., at nine o'clock, the ninety-ninth annual meeting of the society was opened by President George H. Lyman. The recording secretary, treasurer, and committees read their records and reports, as already mentioned in connection with the councilors' meeting.

The next business being the reading of papers and communications, the president introduced J. Orne Green, M. D., of Boston, who read an essay on the Importance of Early Recognition of Ear Disease. He was followed by Peter Pineo, M. D., of Hyannis, in a paper on Cape Cod as a Health Resort, and some Remarks pertaining to Sanitary Science. These papers gave rise to interesting remarks.

The next paper called was that by Dr. H. J. Bigelow on Litholapaxy. Dr. Bigelow, however, did not read, but extemporized a description of his operation, previously giving a brief historical sketch of the growth of lithotomy, exhibiting the various instruments in their development from the primitive to the modern, ingenious, and more useful form, mentioning their advantages and disadvantages, and thus reaching his own instrument and litholapaxy, which he fully demonstrated and described.

Delegates from other societies and visitors from various cities out of the State were then introduced.

Dr. Bronson, of Attleboro', then moved that when the meeting adjourned it should be to four o'clock on the afternoon of the Tuesday preceding the next annual meeting. The motion gave rise to some discussion. Dr. Bronson's reason for his motion being asked, he replied that he wished to bring up a question, now on the table, for discussion in general society at the next annual meeting, and since it was necessary that the question should first be called up at an adjourned meeting, in order to bring it before the society at the

next following meeting, therefore he made his motion. A vote being called for, the motion was decided in the affirmative.

At twelve o'clock the orator of the day, Dr. Thomas H. Gage, delivered his oration. It was marked by eloquence and suggestive good sense.

THE ANNUAL DINNER.

At one o'clock P. M., the Fellows in a body marched to Music Hall, and took their seats at well-spread tables without confusion or loss of time.

The anniversary chairman, Dr. J. Collins Warren, called upon the Rev. William W. Newton to pronounce grace, after which the company attacked the excellent repast. An hour was thus occupied. Dr. Warren then called the society to order, and delivered the following address:—

MR. PRESIDENT, YOUR EXCELLENCY, AND GENTLEMEN OF THE MASSACHUSETTS MEDICAL SOCIETY.—The closing exercises of our annual meeting, which it is now my privilege to conduct, have to-day an unusual significance, for they are those which usher in the one hundredth year of our venerable society. In rising to welcome and to ask you to join with me in the toasts of the day, it is impossible not to be impressed with the scene before me, with a sense of the great power, vigor, and prosperity of our society. During the past few years it has been my business to keep a pretty accurate account of the doings of similar bodies in various parts of the globe. I have watched the proceedings of that marvelously growing association of Great Britain; of the interesting gathering last summer on the continent of Europe known as the International Congress, where men whose names are almost household words to us all composed the rank and file of the meeting; and, lastly, the work of our own national association, whose meeting last week was conducted under the unusually favorable auspices which the talent and hospitality of the great metropolis were able to extend to it; and, Sir, I will venture to say that nowhere in the medical world can so large, harmonious, and enthusiastic a gathering be found as the one which assembles yearly in this hall to do honor to the Massachusetts Medical Society. Our numbers have exceeded for many years those of which any of the societies to which I have referred have been able to boast.

It is an interesting fact and a matter for congratulation that our Alma Mater, though so venerable, was never so vigorous, and never had so large and united a flock as she has to-day. Her career has been a remarkably prosperous one, checkered with but few unfavorable vicissitudes. A champion of liberal views in science and of common sense in practice, she has been looked up to by the better portion of the community as a guide and instructor; and although she has occasionally found it necessary to withhold her assent to some of the many new doctrines which it is the tendency of the day and of this little corner of the world to devise, she has in no way dimmed her prestige or diminished her influence. The venerated founders of our society, were they with us to-day, could not but regard with unmingled satisfaction this gay scene. To what cause is this degree of prosperity due? Mainly, Sir, in my opinion, to two: The men who gathered together, ninety-nine years ago, to form this society were among the most prominent of our patriots, our scientific men, and our citizens. They put their

stamp upon the society, and its impress has endured to the present day.

We have also a machinery in our organization which works nearly to perfection, and this result is mainly due to the public spirit which has actuated our leading members, who have given up a large share of their time to the interests of the society. In a word, there has been always a powerful *esprit de corps*.

In looking into the future, let us hope that no Eve may tempt us to hasty action, that no apple of discord will be thrown into the ranks, and, however radical the changes contemplated may be, that harmony always will prevail. With such sentiments to guide us we can feel authorized in hoping that the past is but a preparation for a future full of influence upon, of promise and usefulness to, the community and the profession.

Dr. Warren then called upon Dr. Williams, president elect, to respond to a toast to "the future of the Massachusetts Medical Society."

Dr. Williams said: I should indeed be unappreciative did I not feel deeply moved, as well as greatly cheered, by this kind reception.

You have made it my privilege to lead the advance in that bright path of honor and usefulness from which this society has never wandered. This present welcome tells me that your hearts have gone with your ballots, and promises a cordial aid in whatever may be done or attempted towards fulfilling the high purposes for which our organization was founded.

It is no empty boast to declare that the beneficent acts of the Massachusetts Medical Society, during almost a hundred years, entitle it and its Fellows to a conspicuous place among those who have deserved well of their country, to such a recognition as no enactment can confer, but which comes as a willing and grateful tribute from the community they have so faithfully served.

Its Fellows are not associated for their own aggrandizement or preferment, but in order that by unselfish coöperation, and by comparison of opinions and experience, they may enlarge their power to benefit humanity.

Devoted to such aims as these, educated as they are not only from the rich stores of knowledge patiently gathered and heedfully culled by wise predecessors, but, moreover, trained in the school of responsibility, that thorough master in the art of teaching, beside whom books and theories sink into insignificance, the earnest, thoughtful men whom I see around me have a title to leadership and a right to speak with authority in matters which concern the public health,—a title and a right not to be challenged by the slave of any narrow dogma, or by the empiric who dares to treat diseases, the nature of which is unknown to him, with drugs, with the effects of which he is unacquainted. It is our privilege to maintain and increase the reputation of our ancient and beloved society; to make its Fellowship not only an honor to be prized and sought for, but a passport which shall be everywhere and always accepted as a title to confidence and respect, because always a guaranty of ample qualification and high character.

The chairman then introduced the retiring president, Dr. George H. Lyman, as one of those prominent men who have made the *esprit de corps* of the society what it is by their active interest.

Dr. Lyman facetiously apologized for the character

of his remarks by saying that in old times the Fellows of the society could fortify themselves at dinner with anaesthetics, which, as you all know, have a charming influence in loosening the tongue; but nowadays we are confined to feed water, a paralyzing drink, especially in hot weather. It is often said that we so-called regulars are dying out. Well, of course, all our skill does not exempt us from the common lot of humanity. But if it be meant that as a society we are decreasing in numbers or in influence, we have only to appeal to the records to show how much mistaken our kind friends are. With them the wish is doubtless father to the thought. The number of well-educated men who yearly seek admission to our ranks certainly show that there is a large demand, and our hard-headed, common-sense New Englanders are not apt to demand, certainly not to pay for, that of which they have no need. And we must not forget, either, that this membership becomes yearly more and more difficult, as the standard of acquirement is made to keep pace with scientific discovery. I am confident that there are very few of us past middle age who would care to undergo the ordeal of an examination such as is required to-day by the Harvard Medical School of its young men. This, after all, is our surest guaranty for the future. The best educated physician will, other things being equal, be the most successful for himself, and the most respected and sought after by the community in which he lives. Who will undertake to estimate the influence of such a large body of men for good, if rightly directed, over the men, the women, and the children of this commonwealth, with whom they alone are brought into such constant and intimate relations? We are standing upon the very limit of the first century of our existence,—a century which has witnessed such a wonderful transformation in relation to the arts and sciences as the world has never before seen. In this progress the American medical profession can justly claim no inconsiderable share. With education for our guide, and the cultivation of every honorable and charitable instinct of our ethics, we may with unhesitating confidence trust our craft upon the unknown seas of the century to come. Let me, in conclusion, hope that every one of us may be present at its inauguration.

Alluding to the absence of the orator of the day, the chairman asked the society to join him in thanking Dr. Gage for his eloquent and sensible address.

He then said, "We are indorsed by the presence of our chief executive. Our State could not be more gracefully represented than in the person of our governor, the Hon. John D. Long."

In responding, Governor Long paid a tribute to the society as one of the most ancient and dignified of the commonwealth, and to the profession of medicine as distinguished by a sense of honor and by the sentiments of benevolence and courage in the discharge of the great responsibilities that rest upon its members, some of whom in every great epidemic have devoted themselves to the necessities of those stricken by disease, with a heroism as true as that exhibited by those who have gone down to the battle-front and sacrificed their lives for their country. He characterized the profession as one devoted in the studies which it pursues to an ardent, straightforward, and conscientious search for the truth. Having alluded to the tender and sympathetic relations into which all at one time or another are brought with the family

physician, he closed with a word of commendation of the wisdom shown in the recent action of the legislature on the bill to regulate and restrict the practice of medicine, saying that the feeling was that it were best to let the medical profession stand where it may well stand.—upon its own merits; that it needed no artificial prop; and that, so far as the profession in Massachusetts was concerned, it had, independent of all adventitious aids, a future before it not less distinguished than its past.

In response to the next sentiment, Dr. Fordyce Barker, of New York, who received a most hearty welcome, made an excellent speech, which sparkled with witty fancies, but was far too lengthy for our space. He complimented the society upon its character, its work, its code of ethics; congratulated the Harvard Medical School upon its successful leadership in advanced system of education. In regard to homeopathy, he said, There is something in human nature which revolts at everything apparently unjust. When the public see men whose honesty of purpose, whose education and scientific attainments they regard as unquestionable, denounced as dishonest, as quacks or knaves, excluded by those whom they consider as belonging to the same guild from not merely professional but social intercourse, is it surprising that their sympathy and even support should be given to what we believe and know to be false in science and futile in practice? I ask if it be not true that at the present day most of us see that, by this mistake in judgment on the part of the profession as a body, a school of medicine has been created and perpetuated for nearly half a century, and supported by a respectable and cultivated minority of society? Is there any one who believes that if the truths which this pseudo school has unquestionably developed had been frankly accepted, its errors kindly exposed, and its individual supporters treated with that wise charity due from a liberal profession, it now would have an existence in the estimation of the public as an antagonistic school?

In reference to women practitioners, he said, I think it is regarded outside the profession as a question of feeling rather than of reason, and that the general sentiment is that if there be those of the fair sex who feel it to be their mission to become healers of the sick, if they demonstrate their fitness for the vocation by the possession of brains and the requisite professional knowledge, they should have the right of trial. Now I will ask whether it will not effectively aid in placing the profession in such public estimation as is its due from its high aims, its importance to the community and to the well-being of society, if we can show to the world that we fear no competition from any quarter, and are ready heartily and gracefully to concede that those who win the epaulettes shall wear them?

The Rev. W. W. Newton responded for the clergy, and vindicated the three professions of medicine, law, and divinity as of equal dignity and necessity, and all of which in their administration call for a conservative regard for great fundamental truths. He felt that each profession had cause for gratitude in the standards and restraints which long experience has established. If charlatanism is abroad, it is not because there is charlatanism in the profession, but because of the imperfection of human nature. There is an element of charity in every man of which he needs to be watch-

ful and against which he should guard himself, and hence is to be inferred the utility of a high standard and a conservative spirit in all the professions.

J. Lewis Stackpole, Esq., responded for the legal profession. He thought it might yet prove practicable to legislate in favor of the scientific practice of medicine by making practitioners somewhat more responsible for the consequences of their acts, either in the way of a penalty imposed or civil damages recoverable. He also suggested that a modification of law in respect to expert testimony would be well, in providing that the expert should be called by the court, and not by the counsel, so that more weight would be attached to such testimony than at present.

Other speeches were made by Dr. John Dillon, as representing the profession in Ireland, Clark Bell, Esq., of New York city, and Dr. Ellis Cole, of San Francisco.

During the two days' meeting Dr. B. Joy Jeffries, with unflinching patience, made use of this new opportunity to test a body of individuals, and having tested two hundred and seventy of the Fellows found sixteen color-blind. Six were incompletely color-blind and ten completely red-blind. The method employed was that of Professor Holmgren, which has been adopted by the United States Army, Navy, and Marine Hospital Service.

In the lower hall of Horticultural Building was an exhibit of surgical instruments, pharmaceutical preparations, and medical books in rather larger than the customary profusion.

It must be said that the dearth of members at the opening meeting and during the early hours of the second day apparently is a sad confession of lack of interest in the papers which are prepared with such care for every yearly gathering of the society. It is a source of mortification to the readers, who, when obliged to read essays, to which they have devoted many studious hours, to a mere handful of listeners, feel not only a sense of stinging neglect, but a thoroughly earnest wish that they had never put pen to paper in such a cause. These essays are not only full of valuable information, but to members who have no opportunity for large reading are pregnant with valuable suggestions. Since Dr. Lyman's inauguration of discussion last year, these papers have called forth remarks of increasing freedom and earnestness. The opportunity for exchange of thought and opinion is so unusual that members should take advantage of it, and spend less time in desultory conversation and in aimless wanderings among the fascinations of instrumental exhibits and of pharmaceutical almoners.

In all other respects this meeting was enjoyable and successful. Probably, however, there have been few councilors' meetings in the history of the Massachusetts Medical Society which were so amiably placid as that of Tuesday evening.

LETTER FROM NEW YORK.

THE AMERICAN MEDICAL ASSOCIATION.

MR. EDITOR, — The meeting of the American Medical Association was a great success in every respect; the attendance being exceedingly large, the scientific proceedings of interest and value, and the social festivities in connection with it all that could be desired. Then the weather behaved in the most charming man-

ner; and it would certainly have been most exhausting to go through the fatigues of such a session in the midst of a sweltering temperature like that which prevailed the week previous. It is true that the morning of the first day was sufficiently hot, and the woes of the unhappy delegates closely packed in the suffocating atmosphere of the registration-room, or waiting in a long line in the broiling sun to get into the place, are not to be underrated; but in the afternoon there was a delightful shower, and from that time forth the weather was simply perfect for such a gathering.

To those of the members who arrived the day before there was quite a treat in the superb Decoration Day street parade, which was the finest ever seen in New York, since, in addition to the entire militia of the city, the Fire Department, and a large turn-out of the Grand Army of the Republic, there was a considerable number of military and other organizations from Philadelphia, Providence, Troy, and other cities in line. The indefatigable permanent secretary of the association, Dr. Atkinson, was on hand on the afternoon of that day, and had nearly two hundred delegates registered before six p. m. The next morning there was a very busy scene at the corner of Fourth Avenue and Twenty-Third Street. "From windows and doorways," to quote from one of the daily newspapers, "placards set forth the virtues of new remedies, the superior advantages of surgical instruments of certain makes, and the trustworthiness of editions of medical works published by particular houses. Messenger-boys hurried to and fro, trucks unloaded tons of books in front of the building, small boys and large men handed out circulars advertising medicines and specimen copies of medical journals, and the passers-by wondered." At eight o'clock the work of registration was resumed, and although by no means completed at the hour of eleven, when the association was to be called to order, an efficient working organization, comprising several hundred names, had been enrolled.

The address of welcome by Professor Thomas, chairman of the committee of arrangements, was conspicuous for the elegance and gracefulness of its style, and the equal grace with which it was delivered. He elicited a tremendous burst of well-deserved applause when he hurled metaphorical anathemas upon those who were accustomed to inveigh against the inefficiency and defects of the association and did all they could to throw obstacles in the way of its advance, and said that if all the best men would only enter its wide-open doors and take an active interest in its welfare it would no longer be heard that it was the representative body of the profession of America only in name.

Professor Sayre presided with much dignity and in a most able manner. He had almost entirely recovered from the serious illness from which he was suffering at the time of his son's death and subsequently to that sad event, and was looking very much better (after a complete rest of some weeks in the enjoyment of the refreshing breezes of Long Island Sound) than his friends had ventured to hope. His excellent address was printed in last week's *JOURNAL*.

Among the distinguished men on the platform at the time of the delivery of the president's address were Dr. S. D. Gross, of Philadelphia, Dr. R. Beverly Cole, of San Francisco, Dr. Hunter McGuire, of Richmond, Dr. T. G. Richardson, of New Orleans, Dr. John L. Atlee, of Lancaster, Pa., Dr. John M. Toner, of Washington, and Drs. J. Marion Sims and T. Gaillard

Thomas, of New York. One very touching incident in the first day's proceedings was the proposal by Professor Gross, in his inimitable manner, of a resolution of sympathy with the president and his bereaved family on account of the untimely death of Dr. Charles H. H. Sayre, and the pronouncing of a brief eulogy upon the deceased. In accordance with the suggestion of Dr. Gross, the resolution was passed by the rising to their feet of the entire association, instead of in the ordinary way of voting.

The proceedings in general session were characterized by harmony and good feeling, and much good work was accomplished in the various sections; nearly one hundred papers being read in these. In the section of Obstetrics and Diseases of Women, Professor Thomas was announced to read an important paper on Ablation of the Uterus for Non-Malignant Tumors, at four o'clock on the second day; but forgetting the hour at which he was to read, he had made an appointment with a number of distinguished gentlemen to perform an ovariectomy at the Woman's Hospital, at half past three. Nevertheless, within five or six minutes after four the operation had been completed, and he was in his place in the section, although the hospital is nearly a mile and a half distant from Association Hall. It was learned afterwards that the ovariectomy had occupied just seventeen minutes altogether; but any one who is acquainted with Dr. Thomas and his way of doing things will not need to be informed that the operation was none the less thorough in every detail on account of the pressure for time than it would otherwise have been. An interesting feature of the proceedings was the establishment of a temporary section on Diseases of Children, with the prospect of its becoming a permanent part of the organization of the association, through the exertions of Professor Abram Jacobi, of New York, who made an appropriate address on the Claims of Pediatric Medicine before the section.

Of course, there was a vast amount of private entertaining on the part of the profession in New York during the session, but the public entertainments were also fully worthy of the occasion. The reception at the Academy of Music, with its delightful promenade concert by Grafulla and the unlimited resources of Delmonico at the disposal of the guests present, was a very brilliant affair, and the superb performance by Mr. Booth of Iago, which is generally acknowledged by the critics to be his most perfect rôle, afforded extreme pleasure to the vast audience which filled the theatre to its utmost capacity. So, too, the receptions at the Academy of Music, by Drs. Barker and Thomas, and at the elegant residences of Mayor Cooper and Mr. Belmont, were most enjoyable, though at times, perhaps, a little too crowded for entire comfort. In the Belmont gallery was afforded an opportunity to the members of the association and their lady friends to see one of the finest private collections of paintings in America.

Finally, the festivities were brought to a close by the delightful excursion up the Hudson and down to Coney Island, provided by Messrs. William Wood and Company, on the mammoth steamboat, *Grand Republic*, with Gilmore's band on board to enliven the sail.

In this connection it may be mentioned that the editor and publishers of the *Record* showed commendable energy in getting out a daily edition of the journal, with reports of all the sections, as well as the general

session of the association, during the meeting. There were twelve hundred delegates in attendance altogether, and it may safely be affirmed that each one of the entire number returned to the ordinary duties of life a happier if not a wiser man. The success of the meeting and its accompanying attractions was largely due to the special efforts of the president, Dr. Sayre, the secretary, Dr. Atkinson, the chairman of the committee of arrangements, Dr. Thomas, the secretary of the same, Dr. Gillette, the chairman of the business committee, Dr. Pallen, and the chairman of the entertainment committee, Dr. Pardee.

THE MEDICAL PROFESSION.

WE fully appreciate the kindly and sympathetic editorial which follows, and which we clip from the *Boston Daily Advertiser* of this morning:—

The ninety-ninth annual meeting of the Massachusetts Medical Society brought together, as usual, a distinguished company of professors, authors, specialists, practitioners, and invited guests. Some pleasant preparations are being made for the centennial celebration; but it is not necessary to wait another year to recognize in the society the twofold element of historic traditions and professional spirit. There were gentlemen present who represent the third and fourth generation of high medical or surgical rank in one and the same family; some gentlemen spoke whose names are honored wherever the art of healing or the science of health has reached its highest development. It is difficult to name all men of eminence, because even the professional associate is overwhelmed by their number and the weight of their names. Meanwhile, the names of Bigelow, Williams, Warren, Shattuck, Lyman, Barker, Bowditch, Chadwick, and others are honored wherever skill and knowledge are held in esteem. And not the least interesting or important fact connected with such an assembly is the observation that the places vacated by retiring gentlemen are filled by worthy successors.

The Massachusetts Medical Society is one of the largest, one of the strongest, and one of the most influential scientific associations in existence. It has always been exclusive in the professional sense of the term; it has always measured its members by a severe standard; it has always watched over public health with caution and prudence; and the statute book of the commonwealth is indebted to it for many enactments which have proved a public protection and a blessing. In medical education Massachusetts has always been a leader, relatively and absolutely, and its medical society has seen to it that the achievements of the profession in other ages and other countries are properly utilized by the profession at home. It has been free from false liberalism, preferring to err, if at all, on the safe side. Meanwhile, the path of the profession, while seemingly narrow and thorny to the common mind, has been pursued steadily and nobly, leading safely into and out of many mysteries, and leaving safe guides behind for future generations. For next to healing or relieving the sick the profession means to make sure of what has been safely established.

It is due to the younger generation to recognize its scientific spirit. More minds than ever are now en-

gaged in the discovery of medical knowledge for its own sake, fondly trusting that a real discovery of scientific value will enrich the profession and enhance the efficiency of its art. Massachusetts has enlarged the domain of accurate and professional medicine. Its medical gentlemen have kept abreast of their profession, and it would be rash indeed to ask of them less learning or less strictness in adhering to the narrow path. Those professions which tried to be liberal, as the alluring phrase is, have not gained in consequence. The world honors the conservative bank; it does not complain when universities draw sharp lines; it declines to respect the judge who disregards the law that some side may be pleased; it reverts the professional man who is loyal to his vocation. Men can be treated liberally and forgivingly; but truth and science abhor easy-going votaries. A problem in mathematics wants to be solved, not patronized or liked. A stern profession wants close disciples, or none. All honor, then, to the Massachusetts Medical Society, now in its centennial year.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U. S. ARMY, FROM MAY 29, 1880, TO JUNE 4, 1880.

VOLLUM, E. P., major and surgeon. Having reported in person at these headquarters, is assigned to duty at Fort Hamilton, New York harbor. S. O. 84, Department of the East, June 1, 1880.

IRWIN, B. J. D., major and surgeon. To be relieved from duty at Fort Meade upon return to that post of Assistant Surgeon Breechenin, and then to report in person to commanding officer, Fort Snelling, Minn., for duty as post surgeon. S. O. 63, Department of Dakota, May 27, 1880.

HAYESSETT, J. C. G., major and surgeon. Granted leave of absence for three months, to take effect when relieved from duty in Department of the East. S. O. 118, A. G. O., May 28, 1880.

BYRNE, C. B., captain and assistant surgeon. Assigned to duty at Fort Johnston, North Carolina, relieving Assistant Surgeon V. Hatvard, who will comply with S. G. 74, C. S., A. G. O., S. O. 65, Department of South, June 1, 1880.

HALL, WILLIAM R., first lieutenant and assistant surgeon. To proceed to Fort Hays, Kansas, and report to Major Noyes, Fourth Cavalry, for duty with troops ordered to New Mexico. S. O. 113, Department of the Missouri, May 26, 1880.

WEISEL, D., captain and assistant surgeon. Granted leave of absence for four months. S. O. 122, A. G. O., June 3, 1880.

NORFOLK DISTRICT MEDICAL SOCIETY.—At the annual meeting of the Norfolk District Medical Society, held on May 11, 1880, the following officers were elected for the ensuing year: President, Robert Anory, M. D.; Vice-President, W. C. B. Field, M. D.; Secretary, Librarian, and Recorder, Walter Channing, M. D.; Treasurer, Norman Call, M. D.; Committee on Trials, James Morion, M. D.; Censors, J. W. Chase, M. D., E. D. Peters, M. D., O. F. Rogers, M. D., G. K. Sabine, M. D., E. T. Williams, M. D.; Councilors, W. S. Everett, M. D., A. R. Holmes, M. D., T. H. Denning, M. D., S. E. Stone, M. D., J. H. Gilbert, M. D., G. W. Fay, M. D., P. O. Edson, M. D., J. H. Streeter, M. D., D. D. Gilbert, M. D., C. E. Stedman, M. D., W. P. Bolles, M. D., J. S. Flint, M. D., D. S. Fogg, M. D., H. P. Bowditch, M. D.; Nominating Councilor, W. P. Bolles, M. D.

BOOKS AND PAMPHLETS RECEIVED.—On the Relations of the Medical Profession to the Trade Interests of the Materia Medica. By Edward R. Squibb, M. D. (Reprint.)

Contributions to the Physiology and Pathology of the Nervous System. Part II. By Isaac Ott, M. D., and J. C. Schlegel, M. D. Pathogenetic Outlines of Homoeopathic Drugs. By Dr. Carl Heineke, of Leipzig. Translated by Emil Tietze, M. D., of Philadelphia. New York and Philadelphia: Boericke and Tafel, 1880.

The Diagnosis of Diseases of the Spinal Cord. By W. R. Gowers, M. D., F. R. C. P. London: J. and A. Churchill, 1880.

Lectures.

CLINICAL LECTURES ON ORTHOPÆDIC SURGERY.¹

DELIVERED AT BELLEVUE HOSPITAL, NEW YORK.

BY LEWIS A. SAYRE, M. D.,

Professor of Orthopædic Surgery and Clinical Surgery in Bellevue Hospital Medical College.

VI. CHRONIC DISEASE OF THE WRIST-JOINT.

GENTLEMEN, — I have to-day an interesting case of disease of the wrist-joint, which I wish to present to you and to make the text for a few general remarks. The patient is a man thirty-six years of age, a carpenter by occupation, and has been brought to me by his physician from New Jersey. The trouble from which he is suffering is the result of a blow that he received more than two years and a half ago, previous to which time he always enjoyed good health. While engaged in his usual avocations he was struck with a hammer on the external radial surface of the wrist-joint. He continued to work for two months after the accident, which occurred in June, 1877; but as the injured wrist kept growing worse all the time, he was finally obliged to abandon his occupation altogether. To relieve the existing inflammation poultices were applied, and at length an abscess opened on the internal aspect of the wrist. The part was then blistered with iodine, and to such an extent that we find the cicatrices that resulted still remaining.

Now what we have here to-day is simply the result of inflammation of the wrist-joint, which was set up by an ordinary blow, and which was not properly attended to at the time when it commenced. In consequence of the neglect at first and the subsequent mismanagement to which it was subjected, the inflammatory process has gone on until, as you see, it has produced subluxation of the joint, with the hand flexed permanently at an angle of about a hundred and eighty degrees, and the ulna, which is completely dislocated backwards, projecting fully half an inch. And not only do we find this well-marked deformity, but also great suffering, and the pain becomes most agonizing if by any means the surfaces entering into the composition of the joint are crowded together. Here, then, is an excellent specimen of chronic disease of the wrist-joint, resulting in disintegration from absorption of the articulating surfaces, and consequent deformity; all of which might have been avoided if the original trouble had been treated by continued extension. This, I learn, has never been applied in the case. Now disease of any joint which continues for a few months will inevitably produce reflex muscular contractions, which not only aggravate the affection by assisting absorption of the articulating surfaces in consequence of the pressure which they uninterruptedly keep up, but also finally result in such deformity as you see here, which is regulated in extent by the muscles concerned. The flexor muscles are of course much more powerful than the extensor ones, and hence the resistance of the latter is gradually overcome by the force of the former. If these two sets of muscles were equal in power, in such a case as this, instead of the kind of deformity which exists here, we should have the hand simply drawn

upward, with disintegration of the bones and cartilages of the joint under the continued pressure.

The special character of the deformity that is here present, therefore, is due to the superior power of the flexor muscles of the fore-arm. In order that the effect of treatment may be fully appreciated in such a case, a plaster cast of the joint should always be taken before commencing it, as this exhibits the real condition of the parts in a much more perfect manner than any photograph or drawing can possibly do.

Now let me show you what the effect of extension, made in the proper direction, will be even at this late stage of the disease. The doctor making firm resistance at the bend of the elbow, I take the man's fingers and thumb in my hands and make extension at the same time that I practice supination. By this simple procedure you observe that I at once diminish the deformity to a considerable extent, and not only does this cause no pain, but it makes the inflamed parts absolutely comfortable, as you can readily see by the relieved expression of his countenance. In the course of a few hours I have no doubt that I could in this way completely straighten out this deformed condition; which, indeed, should never have been allowed to occur.

From the above facts I think none of you can fail to appreciate the important lesson that is to be gathered from a case like this. With all the earnestness that I can possibly command, I beg of you never to forget that unless some interference is made chronic disease of the joints inevitably produces reflex muscular contractions, and that these contractions just as surely aggravate the disease and result in deformity, such as is seen in the case before you. This is half the lesson. The other half is that all the bad effects of these muscular contractions can be successfully overcome by keeping up proper extension during the acute stages of the disease.

For instance, if in the present case I could sit here indefinitely, holding the patient's hand in the manner that I do now, it would be the best method of treatment that could possibly be resorted to, because there is no instrument or apparatus that can at all equal the human hand in delicacy and applicability; but as this is manifestly out of the question, we shall have to adopt instead the best means at our command for the purpose. Now let me convince you that the plan of treatment by extension, of which I have spoken to you, is the only correct one in these cases. While I held the patient's hand in the manner described he is, as I have said, perfectly at ease; but the moment I let go an instantaneous spasm is produced by the impact of the diseased surfaces, in consequence of the muscular contraction, and the man jumps to his feet with the pain. If, now, any pressure, however slight, should be used to crowd the surfaces still more closely together, it would increase the pain a hundred fold, while if motion should be made in the joint, with the parts in this condition, he would suffer the most inexpressible agony.

Is it any wonder, then, that a patient with one of his joints in this condition, which causes him uninterrupted and intense suffering, and keeps up a constant strain upon the whole system, should eventually suffer marked constitutional disturbance in consequence? When these constitutional results occur, he is supposed to be suffering from *serofidous* disease of the joint, although there may not be, and in the vast ma-

¹ Reported for the JOURNAL.

pority of instances there is not, the slightest scrofulous element about the case. The trouble is that the original injury is usually of such a trifling nature that it is allowed to pass almost unheeded, and the patient goes about his ordinary business without thinking it worth while to do anything for it. If this man had had his hand almost half cut off, he would have been all right long ago, because he would have gone at once to a surgeon and had it properly attended to; but the seeming "Libernianism," that "the less you are hurt the worse it is for you," often comes true in point of fact, on account of the time that is lost and the suffering that is endured before one finally recovers from the effects of an injury trivial in itself. The principles here laid down are applicable to all diseases of the joints. Only get a correct comprehension of the pathology in any case that may come under your care, and then, and then only, will you be able to treat it to advantage.

But now as to the treatment to be adopted here. The muscles and tendons may have remained so long contracted in this case that they have become *contractured*, as it is called, or, in other words, structurally shortened. Such a marked deformity cannot be reduced in a moment, and in treating it the important question first comes up, Can the contraction of the muscles and tendons be overcome by gradual traction, or will it be necessary to cut any of them? On making joint-pressure here while the muscles are on the stretch, I find that no reflex contractions are produced by it, and this at once convinces me that with the aid of gradual traction, maintained for a sufficient length of time, they can be fully restored to their original position; whereas, if reflex contractions had thus been caused, such gradual traction would have been of no service whatever, and we should have been obliged to use the knife. What we have to do, then, is to maintain extension and counter-extension, and at the same time keep the parts perfectly at rest. This can be most easily done by means of a piece of sole-leather about the width of half the circumference of the limb, and sufficiently long to reach from the upper part of the fore-arm to the extremities of the fingers, molded to the surface, and properly secured to the limb. Having cut the sole-leather the required shape, we dip it in cold water, and mold it accurately to the part, while the hand is extended in the position that overcomes the deformity to the greatest extent, after which we secure it by means of a roller. When the latter has been put on we should look carefully at the circulation of the finger ends, which should be left exposed, and if this is at all interfered with the bandage should immediately be taken off and reapplied. This dressing having now been properly adjusted, we find that the patient is entirely free from pain. To-morrow, when the leather splint has become perfectly hard, it will be taken off, lined with adhesive plaster, which should lap a couple of inches or more, and then bound again to the limb (extended as before), with the plaster against the fore-arm.

In this way permanent extension and counter-extension will be maintained, and the diseased surfaces of the joint consequently kept from coming in contact with each other. In a few days later, when the deformity has become to a certain extent reduced, the splint can be taken off and remolded to the part; and this can be repeated as often as necessary, until a cure has been effected.

THE COMMITMENT AND CERTIFICATION OF THE INSANE.

BY THEO. W. FISHER, M. D. HARV.

A YEAR has passed since the Board of Health, Lunacy, and Charity was established, and the new law relating to the commitment of the insane enacted. Some comments and suggestions relating to the operation of these measures may not be premature at the present time. There had been for several years a certain pressure in favor of a lunacy commission to which should be given the functions of the old Board of State Charities, relating to lunacy, with such new powers as might seem desirable. There had also been in 1878 a legislative attempt to consolidate the management of the state institutions of all kinds under one central board, for convenience and economy. In 1879 the political pressure for economical administration was great, and any measure likely to result in a saving of expense was welcome in the legislature.

I am assured, however, that the union of the Board of Charities and the Board of Health with new functions relating to lunacy was advocated by Governor Talbot on purely administrative grounds, without any reference whatever to politics. It was believed that the Board of Health had accomplished a good work in the community at large in our own State, and an important missionary work in other States, and that it might now be properly called on to attend to the health interests of the state institutions. It was thought desirable that affairs relating to public health and public charities, which run so nearly parallel, should be under the supervision of a single board, thus avoiding complications and possible conflict of authority. A separate commission of lunacy could also be avoided by giving this board the supervision of the insane. The result was our tripartite Board of Health, Lunacy, and Charity.

Many physicians, who had been proud of the good work achieved by our State Board of Health, regretted the loss of identity which seemed to result from its immersion in the new board. They also shared the fears of Dr. Bowditch in respect to its future usefulness. It is necessary, however, to accept this consolidation as an accomplished fact, and make the best of it. Time will prove or disprove the wisdom of the change. Meanwhile, the new board should have the cordial support of all physicians who desire to promote social and sanitary reform. If a separate or supplementary health report be annually issued, it will stand as evidence of the comparative independence and efficiency of the health department.

Of the composition of the board I should not speak, except for the petition recently circulated to appoint one or more women in the place of two members of the lunacy department, whose terms soon expire. The functions of this department particularly should be exercised in the most purely judicial manner, and it should have the unquestioning confidence of the whole community and of the managers of our insane asylums also. It should no more be suspected of a hypercritical or hostile attitude towards asylums than of undue partiality towards them. Its action should always be based on the longest experience and most scientific information obtainable. If extremists are to be considered eligible to appointment, opposites should

be chosen, the most conservative as well as the most radical. I would willingly see a woman of the right sort appointed, and would also like to see upon the board some ex-superintendent who has made a life-long study of insanity from the inside.

The general powers in relation to the insane given the new board are contained in the Acts of 1879, Chapter 291, Section 3, and are as follows:—

"Said board shall act as commissioners of lunacy, with power to investigate the question of the insanity and condition of any person committed to any lunatic hospital, public or private, or restrained of his liberty by reason of alleged insanity at any place within this commonwealth, and shall discharge any person so committed or restrained if, in their opinion, such person is not insane, or can be cared for after such discharge without danger to others and with benefit to such person. And the members of said board, in person or by agents, shall visit and inspect every private asylum or receptacle for the insane within the commonwealth at least once in every six months."

Under this authority it is to be presumed that in the present full condition of all the state hospitals the policy of removing proper cases to town and state almshouses, or of discharging them to friends, will be frequently exercised. Every physician should therefore carefully consider before certifying in any case of lunacy whether a hospital is, under all the circumstances, the best and only proper place for the patient. His action, if the patient is committed, will be subject to examination by the board or its agent, and possibly to revision by a discharge to friends or transfer to an almshouse. While hospitals remain uncrowded it is desirable to care for as many harmless chronic insane as their accommodations will allow, but this class ought not to be permitted to crowd out cases more urgently demanding treatment and custody.

The new law in relation to the commitment of the insane remains, at the close of another legislative session, unaltered. It was the product, in part, of a popular demand, not entirely spontaneous, and based on exaggerated fears and unreasonable prejudices. It should, however, be considered impartially, and judged by its practical working. In Suffolk County the law has, I believe, been carried out faithfully, and even stringently in most of its provisions. The presence of the insane person in court has usually been required, and some judges have visited the patient out of court when his condition demanded it. The instances in which the personal appearance of the patient has been dispensed with, and reasons therefor given by the judge, have, in my experience, been very few. Great physical debility, with extreme excitement, in an undoubted case of insanity, has furnished the usual excuse. In a large number of cases the patient is willing to go to the hospital, but if able he is expected to come into court and tell the judge so. I remember one lady who considered the hospital a second home, and, having taken up her residence there, sent a polite request to the judge to be excused from attendance, which was granted.

I am not aware that the new law has diminished the number of commitments, or has proved much of a safeguard against fraud or improper certification. It was framed to meet an imaginary evil, and to guard against danger almost wholly chimerical. The result has been to put patients, their friends and physicians, to considerable trouble and annoyance without other

adequate compensation than the satisfaction of popular clamor, and in this direction the result does seem to have been satisfactory so far. In certain cases the effect on the patient of appearing in court has been disturbing, and in some degree, no doubt, harmful. Melancholy patients, believing they have done some great wrong or committed some enormous crime, and, full of apprehensions of impending evil, are very apt to think the judicial process of commitment relates to their punishment. It confirms their delusions, strengthens their apprehensions, and sends them to the hospital under the burden of an imaginary sentence of death. Occasionally a patient falls on her knees in court in prayer, or piteously begs for mercy. The exhibition of these and other deplorable insane conditions even before the few attendants in a probate court room is sometimes a painful one. The English law does not require the patient's presence in court.

It should be observed that this feature tends to render the admission to hospital of certain cases difficult until the disease has reached a stage of chronicity in which treatment is of little avail. Patients and their friends shrink from this additional publicity, and fear an aggravation of the disease instead of its removal. Some cases of undoubted insanity, of the emotional or moral type,—dangerous, it may be, and at least very destructive of family and public peace,—are likely to be refused commitment, because the judge cannot discover the insanity. Such patients are more likely hereafter to go on to the commission of some act, for which they may be punished, or which requires an elaborate defense on the ground of insanity. Insane drunkards are allowed full swing, under the new law, unless they consent to their own confinement. The State should at least legislate upon this last rather frequent form of insanity.

The whole tendency of recent legislation and of lunacy reform, as known to the public, is to remove the insane person from family and medical control, and place him in the hands of the law. The physician's opinion of insanity must be supported by such facts as would satisfy a non-professional observer that the person was insane. The judge must be able to discover the insanity, either in the evidence or the patient's condition. Any lawyer may visit his insane client by order of the judge who committed him. No physician connected with any insane asylum, however experienced, can certify in any case of insanity, although his testimony as an expert will be taken in court. His opinion may determine the disposal of an estate, and the life of an insane homicide is often in his hands, but he cannot certify a demented patient from his own hospital into another. He really stands as family physician to many of his patients, but he cannot certify in any obscure case, although his testimony may be absolutely necessary to its proper disposal. In consequence of a law passed last winter the same discrimination holds in the matter of fees. The physician, whose reputation is at stake and whose practice may suffer through an error, who takes the chief risk of suits, in revenge or on speculation, who perhaps has visited the lunatic under circumstances of great personal risk, and without whose certificate no action can be inaugurated and no arrest made, gets two dollars and mileage. The justice, who sits in his chair and devotes five minutes to the case, gets three dollars, and a dollar extra if he visits the patient.

Aside from the absurdly inadequate fee, and the in-

creased trouble of getting the patient and all his friends into court at a time convenient to him, the physician ought, on some accounts, to be pleased with the new law. It is a great protection, though not a perfect safeguard, against suits for false certification, fraud, and conspiracy, to bring the patient into court and let him have his hearing once for all. It also divides the responsibility to have his friends appear with him. There is less chance that some impetuous and unscrupulous lawyer will conspire with the discharged but still irresponsible lunatic to put respectable physicians on their defense for fraud and perjury "on speculation." In many cases also it is a benefit to the patient to feel that he is judicially committed to an asylum, and that he need not waste valuable time in trying to get out, when he should be trying to get well. Superintendents are not so likely to be importuned for immediate discharge on the ground of hasty and unjust commitment.

The feature of the law requiring the physician to be a graduate of some legally organized medical college is of course a good one. The other requirement, that the certifying physicians shall specify the facts on which their opinion is founded, is, I fear, not generally understood. Many physicians, to my knowledge, still seem to consider the opinion that the patient is insane and a fit subject for hospital treatment as the important part of their certificate. They answer the questions attached to the Suffolk County blanks at least in a brief way, or not at all, and do not attempt to give the facts on which their opinion is based. One certificate, recently, contained only such information as could be derived from the single word "violent." It must be borne in mind that the physician is no longer the judge of the patient's insanity. He must so fortify his opinion with facts that the judge or justice shall be able to infer the existence of insanity. Unless this is done his certificate is not legal in form or substance.

Physicians should also remember that all their certificates now pass a critical examination, by order of the Board of Health, Lunacy, and Charity. Under English law, if not in accordance with the law, their certificates are returned to them for correction. Mr. F. B. Sanborn, inspector of charities, is charged with this duty, and he informs me that large numbers of certificates are wanting in the necessary specification of facts. It should be a matter of professional pride, as well as of obedience to law to make such a statement in every case as will justify the physician's opinion. This will be done when its necessity is generally understood. Certification in cases of persons arrested by the police, or otherwise brought to the notice of the proper authorities for summary disposal, is sometimes difficult. There may be entire lack of information, except what can be gathered from a stupid, demented, intoxicated, delirious, or incoherent person himself, and little time to obtain it. But this excuse will seldom apply to the certificates of physicians, who see patients in their homes, where delay is possible and all the facts are at hand.

Facts of hearsay as well as of observation may be given in the certificate, but they should be carefully distinguished. The two physicians should also specify any facts they may have separately observed. For instance, the one most familiar with the case may say, "Dr. A. observed," etc., and "was informed by the patient's wife that he," etc. Dr. B., if his information is identical, can say so over his own initials or signature.

If not, he can add his facts in the same manner as Dr. A. The questions on some certificate blanks may be answered thus indirectly, and not in a categorical manner, as they are also answered on the statement required by law.

It requires some knowledge of insanity and some experience in certifying to make a perfectly correct certificate, with nothing superfluous, and complete in all respects. Any physician, however, who has come to the conclusion that a person is insane ought to be able to state clearly the facts which led him to this opinion. A careful setting forth of his reasons in the certificate will not only give clearness to his own ideas on the subject, but will prevent hasty action in doubtful or obscure cases. Although the English law differs somewhat from ours in its requirements, Dr. Brushfield's recent article *On Medical Certificates of Insanity*¹ will prove a useful guide to those desirous of perfecting themselves in the art of certificate-making. Our law does not particularize as to the form of the medical portion of the certificate, and makes no distinction between public and private patients. The English law requires but one certificate in the case of paupers, and most of the restrictions and safeguards seem to apply especially to private patients.

Dr. Brushfield considers the certificate as containing two distinct parts,—the statutory and the medical. In the case of private patients the two physicians must separately examine the patient and form an opinion, each independently of the other. Their certificates must be on separate sheets of paper, and neither must see that of the other or know its contents. The statement as to medical qualifications must be full, showing that the medical man is a licensed practitioner, and that he is in actual practice. The time and place of examination must be designated. It should be noted that in neither the English certificate nor ours is it necessary to state that the patient is dangerous. The words "and is a proper person to be taken charge of and detained under care and treatment" are equivalent to "is a proper subject for treatment in an insane hospital" of our certificate. This point should be insisted on, as lawyers and judges in some cases with us seem to think the element of danger the only important one in disputed cases. In the case of *Notridge v. Ripley* the judge appeared to be of opinion that no insane person not dangerous to himself or others ought to be confined in an asylum. The English commissioners of lunacy, in reference to this case, wrote to the lord chancellor as follows: "The object of these acts is not, as your lordship is aware, so much to confine lunatics as to restore to a healthy state of mind such of them as are curable, and to afford comfort and protection to the rest."²

This opinion should be our guide in certifying, since the difficulty of ascertaining dangerous proclivities is great, and their detection may require prolonged observation. It is not necessary to wait till a patient has committed some violent act before certifying, as the non-existence of dangerous symptoms is not a reason against removal to an asylum, whether the patient is private or public. The patient, under English law, must go to an asylum within seven days of his examination by the physicians. With us this is discretionary with the judge. Our certificates must have been made within five days of the examination. The hear-

¹ London Lancet, April 24th, May 1st and 8th, et seq.

² Jurisprudence of Insanity, Brown, page 30.

ing is usually within a day or two, and the patient is sent to the asylum at once. Now and then a delay of a day or two unavoidably occurs. One other requirement, that the patient must not be examined in the asylum where he is to remain, is occasionally disregarded with us.

Dr. Brushfield thinks the greatest modern improvement in the lunacy law is that portion which requires physicians to state the reasons or "grounds" for their opinion that a person is insane in detail. It is no doubt a great improvement, but here physicians conversant with insanity always have stated their reasons more or less in detail, and supposed they were testifying to them under oath. It is well to have the law made clear on this point, and the practice should conform to it. Under the old law it was my aim in certifying to present as clear an idea of the form of insanity in each case as possible, under the headings of cause, duration, previous attacks, disposition, habits in regard to temperance, etc. This is now superfluous, or at least subordinate to the presentation of facts proving the insanity. These may by some ingenuity still be arranged so as to show that the physician knows what form of mental disease he is observing, but he must at any rate show by his facts that the party is insane. He is still supposed to give a medical opinion, but if his facts do not justify his opinion in the mind of a non-professional justice it will be without weight.

I am not sure of the advantages of some other requirements of the English law: that, for instance, confining the physician, however familiar with the case, to a statement of facts observed on some particular day, to the exclusion of all others, and that forbidding consultation between the certifying physicians. Why should the medical man about to certify be deprived of the experience of the family physician in forming his opinion? To be of any value it should be based on all the facts of the case obtainable, and not on the chance developments of an hour's examination. Why not set up some legal test of honesty and capacity, and then let physicians consult as in case of any other disease? Public examiners who could be trusted might better be appointed than to hamper the physician in search for the truth with too many restrictions. The English law seems designed to hold in check a set of medical villains who are desperately conspiring for money to put sane people into the licensed houses of other base physicians for their pecuniary profit.

The provision that no asylum superintendent shall certify a patient into his own hospital is so eminently proper, and the act so little likely to occur, as hardly to require legislation. Our legislature has, however, gone a step beyond this feature of the English law, and forbids an asylum physician to certify a patient into any hospital. He may neither be peculiarly interested in his own nor any other asylum, but he is not to be trusted. The reason for this provision in our law was not, I believe, pecuniary. It was said that persons of long hospital experience with the insane knew too much about insanity, and could easily snap up a demented legislator or a crazy lobbyist, and consign him or her to the Bastille at Somerville! This would be laughable if it were not insulting to a body of as intelligent and trustworthy servants of the State as any to be found in our legislative halls.

This English legislation, which we have in part copied, grew out of a state of things never existing here. Until recently no private asylums were to be found

here, and there is no probability that the small houses for private patients kept by physicians for their own profit will ever become so numerous as to require a special method of certification. Our law has the good feature of treating rich and poor alike. The safeguards against improper commitments protect one class as much as the other. In England a single certificate only is required in case of a pauper. If he be in an almshouse the certificate of the medical officer and an order from a justice, a relieving officer, or an officiating clergyman is sufficient.¹

Upon the medical portion of the certificate Dr. Brushfield remarks that the physician should always bear in mind that he may have to defend his certificate in court. If the symptoms on the day of examination are obscure he must not certify, no matter how dangerous to himself or others the lunatic may have been. In epileptic mania, homicidal impulse, or suicidal mania the symptoms are very likely to be in abeyance at the time of examination; but the friends must be warned and the certificate refused, however strong the hearsay evidence may be.

All the chief symptoms should be detailed briefly, without comment or repetition. Statements represented as delusions which might by any possibility be true should be carefully investigated. Dr. Brushfield relates the case of an engineer whose claim of having made plans for tunneling the English Channel was supposed to be a delusion, but proved true. I remember a sea-captain who died of general paralysis, and who claimed to have discovered an island of solid gum in the Pacific Ocean, which was named after him. This supposed hallucination proved true. I also recently met with a physician who was willing to certify that a discharged lunatic was still insane, because he still claimed to own a silver mine and to have had in his pocket specimens of the ore, which claims were true.

Such physical conditions as blindness, deafness, paralysis, malformations, or loss of teeth, causing defects of speech, infirmities of temper, peculiarities of gesture, eccentricities in conduct, may sometimes make a person seem at first sight insane or demented, and should be allowed for. Change in habit, conversation, affection, disposition, dress, or conduct is more important than peculiarity. Coarse and violent language may indicate insanity in a person of refinement, but not in one of less culture. Care should be taken to use proper terms in describing these symptoms. *Manner*, for instance, is not *incoherent*, nor *conversation* *illusory*. The great difficulty for most physicians in certifying is due to imperfect knowledge of insanity and doubt as to which are the chief symptoms in a given case. Insanity is protean, and no two cases are exactly alike. The peculiarities of each case should be carefully described.

Dr. Brushfield would have the patient's appearance, speech, and conduct observed and described in their order. The attitude and movements as well as facial expression should be described. Occasionally obdurate silence on the part of the patient is an obstacle to certification. This may occur from simple inability, as in fright or shock, but is willful in most cases. Conversation may fail in general inertness, in fatuity, hysteria, melancholia, or from perversity. Try to ascertain the cause, and state it as hearsay if necessary. It has always been my habit to tell such patients that their silence may result in sending them to an asylum, or to

¹ Bucknill and Tuke, 4th edition, page 7.

ask them if they have any objections to going to an asylum.

Delusion is the chief symptom in most cases of insanity, and is accepted as conclusive evidence in courts. Some judges have ruled that without it there is no insanity, which is not in accordance with medical experience. False belief, not arising in cerebro-mental diseases, is of course no proof of insanity; but false beliefs are sometimes contagious, and may produce actual insanity. Hallucination and illusion should be described if they exist. I am aware that physicians often neglect to state the fact of "false hearing," which is an extremely common and a dangerous symptom, sometimes because they do not recognize it as the true explanation of the patient's conduct. Evanescent, extravagant statements, such as general paralytics make, are not properly delusions, as they are not fixed, but are of the nature of delirium. Incoherence is a frequent symptom, and should be carefully observed and noted. It may extend to words, or be limited to a confusion of ideas. It is found in acute mania from a too rapid flow of ideas, and in dementia from loss of control and failure of the thinking powers. Defects of memory are also important and common.

It is not necessary to follow Dr. Brushfield's analysis further. He treats at some length of the method of describing the various symptoms in insanity, and gives many examples of errors in certification. He refers to Dr. Millar's book¹ for further information. I have thus called the attention of the profession in Massachusetts to the present requirements of our law, and have no doubt model certificates in all cases will be the result. It may be said that we are not under English law, and that if the certificate, with the oral testimony of the physicians and the patient's friends, and the presence of the patient himself satisfy the committing magistrate it is enough. I still think that a fair interpretation of the words "and he shall specify the facts on which his opinions are founded" require that the physician shall state facts enough to justify his opinion, to his own mind at least.

THE LEATHER JACKET IN THE TREATMENT OF SPINAL CURVATURE.

BY C. T. HUNTER, M. D.,

Demonstrator of Surgery in the University of Pennsylvania.

DURING the summer of 1878, while on duty in the surgical wards of the Pennsylvania Hospital, I had two cases of ununited fracture of the leg under my charge, which I treated successfully by means of leather splints. The use of this splint was suggested to me by Professor Agnew, who had tried it in similar cases. The leather used was the ordinary sole-leather, which was cut of a size sufficient to envelop the foot and leg; it was softened in water, then applied to the limb, and secured by a bandage. As soon as it had become dry it was removed, both surfaces varnished, several perforations made in it for the purpose of ventilation, and the edges provided with shoe-hooks. Thus prepared, it was applied to the leg, protected by a stocking, and laced up like a shoe, when the patient was permitted to move about on his feet with the aid of crutches.

Soon afterwards I was called in consultation in the case of a young girl, aged twelve, who was supposed to have anterior-posterior curvature of the spine. A care-

ful examination of her back revealed a slight prominence in the mid-lumbar region. As the disease appeared to have made but little progress, it occurred to me that this case would be a suitable one for the use of the sole-leather jacket, prepared as the splints had been which I had previously used for ununited fracture of the leg. To obviate the necessity of fitting the sole-leather on the patient, it was essential that I should first get a cast of her body. To do this I applied a plaster-of-Paris bandage in the usual way, and this, after fifteen or twenty minutes, was removed by cutting it down the front. This plaster jacket was sent to our instrument-maker, Mr. Genrig, who had a cast made from it that corresponded exactly to the body of the patient. On the plaster cast the sole-leather was fashioned, which, when dry, was prepared in the same way as the splint, described above. To prevent excoriation of the integuments covering the folds of the axillæ, the upper margin of the jacket was cut out on each side and faced with buckskin. Thus

fitted, the jacket was applied to our patient August 22d, 1878, and without further alteration was worn by her for a considerable time, with entire relief of the symptoms consequent upon the disease of the vertebrae. Since then this jacket or corset has been extensively used by Professor Agnew in his practice, and by myself in a proportionate extent in my own, with the greatest satisfaction. When the disease is situated in the upper dorsal or cervical region, and it is found necessary to support the head, Professor Sayre's "jury-mast" can be easily attached to the back of the leather splint. In order to make the jacket a little more finished in appearance, Mr. Genrig covers its entire surface with a flesh-colored enamel similar to that used for the same purpose by manufacturers of artificial limbs. At first, these corsets were lined with buckskin or light flannel; but this was found to be superfluous, and added somewhat to the weight of the jacket, because a woolen or cotton under-shirt worn by the patient fulfilled the purposes of a lining.

I do not insist upon the superiority of the leather jacket over the plaster-of-Paris or the silicate-of-sodium corset in all cases of spinal curvature. It is, however, specially advantageous in cases of Pott's disease that are convalescing, and likewise in those of lateral curvature in the early stage, before there is any great amount of lateral deviation of the spine from the perpendicular. In all instances in which a continuous bandage is not specially indicated, the leather jacket is manifestly the best in use. It is fully as firm as the plaster-of-Paris corset, and is not open to the annoyance that frequently arises from plaster which crumbles off and works in between the jacket and the skin of the patient; it is lighter and stronger than the silicate-of-sodium jacket, and is far more durable than either. For the attachment of a head-piece or "jury-mast," I am convinced that the leather jacket far surpasses every other jacket or brace in use.

¹ Hints on Insanity, 2d edition.

THE PROPER USE OF THE HOT VAGINAL DOUCHE.

BY CLIFTON E. WING, M. D.

THE use of hot-water vaginal injections in uterine affections has now become pretty general, but it is evident from the testimony of patients who have followed the directions of their physicians in using them that many practitioners who order them fail to understand the principle of their action, and consequently do not impress upon their patients the proper method of taking them. As often employed they are calculated to do more harm than good.

The great object which they are intended to accomplish is the driving of the blood from the local parts, thus reducing the weight of the uterus and its appendages, removing tenderness due to congestion, and, when inflammation is present, "starving it out by cutting off its nourishment;" for without active congestion active inflammation cannot exist. Moreover, when properly taken, they assist the absorption of products of inflammation, and forward the restoration of the normal mobility and elasticity to the tissues of the parts. In short, they act as does a poultice properly applied to any tender or inflamed external portion of the body.

The effect produced upon the circulation of a part by the application of water varies with the temperature of the water and with the length of time the application lasts. This can be clearly understood if we call to mind its effect upon our hands. If we dip them into *cold water*, during the time they remain in the water—be it longer or shorter—the blood is driven from them and their circulation is diminished; but as soon as they are withdrawn reaction sets in, the hands become red from increased circulation, and this secondary congestion lasts for a considerable time. This effect of temporary cold in producing subsequent congestion is clearly shown in the red hands of the child who has been playing with snow. Were it possible for a patient to employ the vaginal douche constantly for hours and days without intermission, doubtless the uterine circulation could be controlled by such use of cold water; but of course this cannot be carried out in practice, and when employed, as it usually is, for a few minutes only the real effect of the cold-water injection is to produce congestion instead of correcting it.

If the hands are placed in water which is *warm* (not hot) the blood is drawn to them at the time, and they remain more or less red after their withdrawal. Water simply *warm*, then, will not answer the purpose of the vaginal douche in correcting congestion.

If the water is *hot* (as hot as can be borne) and the hands are immersed only for a few moments, again congestion is the result; but if one's hands are kept for a long time in hot water, as in the case of the washerwoman or the kitchen-maid engaged in washing dishes, on removal they are found to be *white, shrunk, and shriveled*, and they do not regain their usual condition perhaps for hours. In brief, by the prolonged application of hot (not warm) water to a part the supply of blood to that part is decidedly lessened, and, moreover, the full circulation is not quickly reestablished when the application ceases. This is exactly what the hot-water vaginal douche is intended to do, and what it will do if the proper precautions are observed in its use.

In the first place, the water used must be hot, and not

warm, as can be readily understood from the foregoing. It is safe to tell the patient to have the water "just as hot as she can bear it without being scalded," for it will burn the skin as it returns from the vagina before it will do any harm to the mucous membrane of the internal parts. After a few times the woman will find herself using water at 110° to 120° Fahrenheit. Occasionally an enthusiastic patient will reason, like the Irishman, that "if some is good more is better," and helped by hot water will try hotter, until some irritation of the parts is the result of her overdoing the matter; but this, if it happens, is a temporary trouble, which, the fault removed, will take care of itself, and generally the error is committed of not having the water hot enough. *Care must always be taken that the water does not get cool before the douche is finished. To guard against this, a very little hot water may be added from time to time to the water used.*

Secondly. *The douche must be used at least twenty minutes (better half an hour or more) at a time. If used for a few minutes only it will, as explained above, cause congestion instead of correcting it. The quantity of water necessary for continuing the injection the proper length of time is not a few pints or quarts, but a number of gallons. It is not the quantity of water used that is of importance, but it is essential that during the whole time of the douche the temperature of the water in the vagina should be kept up, that the parts may be constantly bathed in water considerably higher than the normal temperature of the body.*

The constant flow of hot water is the easiest means of gaining the point.

Thirdly. *The patient should never take the douche in the sitting position, with the body erect, but should always lie flat upon her back, with the hips higher than the rest of the body. If this precaution is not taken the water flows from the end of the injection tube, and at once returns out from the vagina without coming in contact with the womb and upper parts of the vagina, where its effect is wanted. Whereas with the woman on her back, with the hips raised, the womb and what was in the erect posture of the body the upper part of the vagina are now lower than the vaginal outlet; consequently the vagina remains filled with the hot water up to the level of its external opening, and the womb and the adjacent parts get the full benefit of the application.*

Dr. Emmet, to whom full credit is due for introducing the hot vaginal douches, prefers to have them given in all cases by a nurse, and states "a steady stream is never as serviceable as the interrupted current from a Davidson syringe." I cannot agree with this opinion. I believe I have seen fully as good results from the douche where the steady current of a "fountain syringe" or its equivalent was used as where the Davidson syringe was employed by the most skillful nurse; and I had ample opportunity of watching the latter method when an *interne* at the Woman's Hospital in New York, a number of years ago. Furthermore, I feel sure that with many uterine patients it is better to dispense with the services of a nurse, for the constant presence of one who can be called on at any moment for whatever is needed seems in some cases to remove that stimulus for self exertion which is at times such an important adjuvant in the cure. The Davidson syringe cannot be used to advantage by the patient herself. Indeed, it is enough to tire a man's arm to

pump any amount of water through it. The "fountain syringe," as sold in the shops, is of very little value for our purpose, from the fact that its reservoir is altogether too small to hold the requisite amount of water. If used, it must be refilled a number of times. I usually tell my patients to get a common-sized wooden water-pail (which will hold water enough, and can be obtained for very little), to have a hole bored in its side near the bottom, and a small faucet inserted; to attach to this a piece of rubber tubing (such as can be bought at any rubber store) of about the size commonly used on syringes, and from four to six feet long, and to the end of this tubing to attach a vaginal nozzle, such as comes with any common family syringe. This part of the apparatus is then ready. A spring catch may be used upon the tubing further to control the flow of water, if desired.

As stated above, the douche must be taken with the patient lying on her back, with the hips somewhat raised. This can be accomplished in several ways. It can be used while the patient is taking a warm bath; if there is a set bath in the house, the pail filled with hot water being placed upon a stand, or suspended at such a height that the water will flow freely from the tube introduced into the vagina; or the woman can lie crosswise upon a bed, with her hips at the edge and her feet resting upon chairs, a rubber sheet being placed under her in such a way that it will convey the escaping water into a tub placed upon the floor to catch it, and at the same time protect the bed from getting wet.

The best way, however, is to employ a proper bed-pan to receive the water, and use the douche while lying in bed. The common crockery bed-pans hold so little that they require to be emptied several times during the process, and are therefore very inconvenient where the patient takes the injection herself. A nurse can manage better to remove, empty, and replace the pan, or can empty it when full without removing it by employing the syringe for that purpose, but it is troublesome. The shape of the common bed-pan, which is such that it can be readily slid under a patient, is, however, an advantage in some cases of serious inflammation, where it is desirable to avoid lifting or moving the patient more than is absolutely necessary. Some pans are made of this same shape, but with a tube attached, through which the water is drawn off into a proper receptacle placed upon the floor. This does very well if care is taken that the escape of water through the tube does not become stopped, but if this happens a drenched bed is apt to be the result. Ordinarily (especially where the patient manages the douche herself), it is most convenient to make use of a pan which is of sufficient size to hold all the water which is to be used, and which need not be emptied until the douche is ended. With such a pan and a rubber sheet the bed never need be wetted.

The patient should avoid becoming chilled at the time of taking the injection by being sufficiently covered, and should be careful about going out in the cold immediately afterwards unless well wrapped up.

In ordinary cases these injections should be employed twice daily, — in the evening on retiring, and in the morning before getting up. In some cases of severe inflammation they may be used oftener with advantage. It is best to continue them long after the symptoms for which they were used have disappeared rather than omit them too soon, and it is well

to discontinue them by using them at longer and longer intervals, until they are finally omitted, rather than to omit them at once. If the old symptoms return they should be resumed.

In certain cases the amount of comfort afforded is remarkable. I have seen some patients who were "used up" with uterine symptoms, — dysmenorrhœa, backache, inability to walk any distance or stand any length of time without suffering, pain through the hips, etc., — who, when the pelvic congestion was relieved in this way, felt so perfectly well that they required nothing further in the way of treatment.

In closing I cannot do better than quote the following paragraph from an excellent article by Dr. E. C. Dudley, published in the *Chicago Medical Gazette* some months since: "In uterine therapeutics the value of the hot-water vaginal douche is perhaps greater than that of all other topical applications combined; its use is perhaps more nearly universal, yet so inefficiently is it ordinarily applied that in the large majority of cases it does little or no good."

Hospital Practice and Clinical Memoranda.

A FATAL CASE OF FATTY EMBOLISM.

BY MARSHALL L. BROWN, M. D., BRIGHTON, MASS.

W. S., a lad sixteen, had diabetes mellitus, from November, 1869, to March, 1880. The specific gravity of his urine ranged from 1042 at highest down to 1025, the lowest, which last was at the week of his death, with a corresponding diminution in the amount of sugar. The greatest quantity of urine passed any one day during his illness was thirteen quarts. The last month of his life it had considerably diminished. His general condition and appearance did not indicate any settled organic disease or cachexia. His physical strength and vigor of body had seemingly increased. His appetite and digestion had improved, and he was eating a greater variety of food. The second or third day before his death he walked several miles and dined out. On the morning of the day of his death he made arrangements to go into town to see his attending physician; but, as the morning advanced, feeling an uneasiness and uncomfortable sensation in his stomach and bowels, he concluded to have him come out and visit him. On arriving at noon, he found his patient suffering from a diarrhœa which had come on during the forenoon, attended with considerable pain and quickened heart's action.

During the afternoon the pain and diarrhœa increasing, a physician near at hand was called in, who prescribed Squibb's liq. opii comp., in small, frequently repeated doses. In the course of a few hours, "the pain suddenly moved up from the stomach and bowels to the chest," to the cardiac region. He immediately asked to be fanned and to have the windows opened. The pain and dyspnoea constantly increasing, the physician near at hand was called again, who, on his arrival, found the patient in a dying condition. The dyspnoea rapidly increased, and he became as rapidly cyanotic, and died.

At the partial autopsy, forty-eight hours after death, portions of the stomach and bowels were found considerably injected, indicating the location of the abdomi-

nal pains. The liver was somewhat enlarged, and slightly more friable than usual; the kidneys and spleen were also enlarged, but otherwise normal in appearance. Upon applying a diluted solution of tincture of iodine to freshly cut surfaces of each of these organs we did not get the usual reaction which indicates the presence of fatty degeneration. The lungs were generally edematous. The heart appeared normal in size; its color was much paler than usual; the walls of the right ventricle were somewhat thinned, and the right auricle and ventricle were filled with black, tarry masses of blood intermixed with coagulated masses of a white substance, resembling in consistency the curdled milk vomited by a nursing child, and in color the white substance of the brain. These masses varied in size from that of a large pin head to that of a large pea. A collection of it, two to five inches long, was found completely filling the pulmonary artery, and seemed more adherent and firmer than that found in the heart. A portion of this mass was examined under the microscope by one of the physicians present, and found to consist wholly of fat.

The thoracic duct, unfortunately, was not examined. It would have been a matter of great interest to have ascertained whether this fatty matter was coagulated in the thoracic duct or after the chyle and lymph had been intermingled with the blood in the superior vena cava.

The article on Fatty Embolism, in Recent Progress in Pathology and Pathological Anatomy, vol. cii., No. 21, of the JOURNAL, is the only source I have yet found which makes clear and helps to interpret this case. In the light of the facts contained in this article, this would seem to be a clear case of fatty embolism.

Reports of Societies.

ANNUAL MEETING OF THE AMERICAN MEDICAL ASSOCIATION.¹

SECTIONS.

Section I. Practical Medicine. The electrical treatment of exophthalmic goitre was recommended by Dr. A. D. Rockwell, of New York, using galvanic currents.

Dr. J. Solis Cohen's paper on Artificial Inflation of the Lungs in Catarrhal Pulmonary Diseases was read for him by Dr. Bulkley.

Dr. L. Duncan Bulkley next presented a paper On the Use of Sulphur and its Compounds in Diseases of the Skin, both internally and externally. This paper was generally discussed.

The Strong Galvanic Current in the Treatment of Sciatica was the title of a paper by Dr. V. P. Gilney, of New York, in which the stable current, as strong as the patient will bear it, is to be used. The descending current was preferred.

Dr. L. Turnbull read a paper on Hydrobromic Ether, which he considered as a very safe and efficient anæsthetic for operations not exceeding forty minutes.

A paper by Dr. J. J. Caldwell, of Baltimore, on The Study of Special Nerve Centres, and one by Dr. E. Cutter, of Boston, on The Salisbury Method of treating Consumption, were referred to the publication committee.

Section II. Dr. F. N. Otis, of New York, read an essay upon Syphilis, especially in reference to its treatment.

Dr. H. O. Marey, of Massachusetts, described the Development of the Osseous Callus, and illustrated it by micro-photographs beautifully colored.

Dr. Piffard, of St. Louis, explained the pathology of Lupus, and considered it as a scrofulous affection. The histological characteristics of three grades of lupus were shown by the magic lantern. Local treatment by the scoop, with subsequent application of the actual cautery, was recommended.

Dr. Hutchinson, of Brooklyn, presented a communication from Dr. Charles R. Drysdale, of London, England, on The Treatment of Syphilis at the Commencement and End of the Nineteenth Century.

In this paper the non-mercurial treatment of the initial lesion was advised. Where iodine is used, syphilis is generally mild. The dose of mercury ought to be small, and is best in the form of iodide of mercury; but tertiary syphilis is treated by large doses of potassium iodide, using mercury when this fails.

Dr. Martin, of Boston, being invited to speak on the elastic bandage, explained its application.

Dr. H. F. Campbell, of Georgia, gave an abstract of his paper On the Radical Cure of Inflammation by the Ligation of Vessels of Supply. Seven cases of the lower and eight of the upper extremity had been thus treated during inflammation, with surprising results.

Dr. W. D. Hooper, of Liberty, Va., read a paper on Fractures, which had been previously published; and exhibited his appliance for the treatment of fractures.

The following papers were read by title only: A Method of treating Spinal Disease, by E. H. Coover, Pennsylvania; Treatment of Fractures of Long Bones involving the Joints, by James S. Green, of Elizabeth, N. J.; On the Present Standing of the Doctrine of Inflammation, by Dr. C. Heitzmann, New York.

Section III. On Obstetrics and Diseases of Women. Dr. Addinell Hewson read a volunteer paper on the Treatment of Fibroids of the Uterus by Dry Earth. Fifty cases had been treated in this way, with great relief to the swelling and tenderness and reduction in size of the growth.

Dr. B. F. Dawson, of New York, presented a clinical report on a Modified Operation for Cystocele, in which the redundant anterior wall of the vagina was folded into the bladder.

Dr. Robert Battey, of Rome, Ga., reported a case of still-birth, with resuscitation after two hours and five minutes. It was a breech presentation, and greatly cyanosed. After one hour's artificial respiration it took the first breath, but was not resuscitated fully until the time named. The child died shortly afterward.

Dr. Palmer, on behalf of Dr. T. G. Thomas, presented a very fine dermoid cyst of the ovary, removed a few days before.

Dr. K. Tauszky, of New York, read a paper entitled Rest after Delivery, and the Treatment of Peritonitis, in which he deprecated too early rising after delivery.

Dr. R. Beverly Cole, of San Francisco, made some Remarks upon Sponge Tents, in which he described his method of preparing them. Taking fine cap-sponge perfectly free from grit, he dips it in melted wax and subjects it to pressure. From this the tents may be cut of any desired shape.

Dr. Battey exhibited a soft rubber catheter attached

¹ Continued from page 565.

to a long piece of ordinary rubber tubing, so as to carry the urine outside of the bed.

Section IV. State Medicine. Dr. Wines, of the Census Bureau, by invitation, explained the blanks upon which the present census is taken. Dr. Billings offered the following resolution which was adopted:—

"Resolved, That this Association approves of the plans proposed by the superintendent of the tenth census for the collection of data with regard to the insane and idiots of the United States, and that it urges upon physicians that they should aid in this work as far as possible by carefully replying to the schedule of queries on this subject which will be sent them from the census office."

Dr. Chas. W. Page, of Hartford, Conn., read a paper on the Moral Treatment of the Insane.

The report of the committee appointed at Buffalo to consider the Intervention of the Physician in Education discussed very fully the unhygienic condition of the ventilation, sewage, etc., of public schools.

The report upon Sanitaria stated that the committee considered it inexpedient to recommend any particular sanitarium.

Dr. Bell offered the following resolution, which was adopted:—

"Resolved, That a general sanitary organization is a necessity of every enlightened commercial nation, and the service of the National Board of Health of the United States, since its organization, has been such as to impress us that both in its personnel and organization it is entitled to the confidence of the government and the people; and we join the American Public Health Association and the National Academy of Sciences in earnestly recommending to Congress that the suggestions and estimates of the board receive their legal sanction, believing that the money asked for is necessary to the work of the board, and will be a most judicious expenditure of money."

Dr. A. L. Carroll, of New Brighton, N. Y., offered a resolution requesting the establishment of a chair of Public or State Medicine as an essential part of its curriculum, which was adopted.

Dr. Quimby, of Jersey City, read a paper on the Criminal use of Chloroform, which supported the view that this agent might be given during sleep, without awaking the subject.¹

Dr. W. H. Lathrop spoke about the proper construction of almshouses.

Dr. Antisell, of Washington, D. C., advocated the appointment of a medical analyst to act in conjunction with the coroner, in cases of suspected poisoning; and Dr. W. F. Thoms offered some considerations on Humane Societies.

Section V. Dr. B. Joy Jeffries read a very instructive and suggestive paper on Color-Blindness, in which the importance of the subject was dwelt upon, and the great preponderance of the disorder in males noticed.

Dr. David Hunt, of Boston, read a paper on the Variability of the Human Eye.

Dr. Richard C. Brandeis read a paper entitled 'The Probable Cause of some Forms of Globus Hystericus, which he thought might be due to the temporary incarceration of the epiglottis by the enlarged papilla: circumvallata. Treatment by caustics and cautery of these glands was recommended.

Dr. E. Gruening, New York, exhibited a magnet for the removal of particles of iron from the eye.

Dr. H. L. Knapp made some remarks upon Perichondritis Auriculae, in which relief was afforded by pressure.

Dr. T. R. Pooley presented a paper On the Detection of the Presence and Location of Pieces of Steel and Iron in the Eye by the Indication of a Magnetic Needle. The magnet being suspended by a silk thread, the foreign body is made a magnet by induction, and the needle is then brought in its vicinity.

Dr. S. D. Risley volunteered a paper on Ear Troubles, and reported a case of trephining of the mastoid for inflammation of the mastoid cells.

Dr. E. S. Peck presented a case of Primary Conjunctival Lupus.

Dr. W. F. Holcombe, of New York, presented the following papers, which were read by title: Removal of Secretions from the Tympanic Cavity and Mastoid Cells. Causes and Relief of Tinnitus Aurium, A Treatment suggested for Sabacuta and Chronic Otitis Media.

The paper of Dr. L. Turnbull, entitled Observations, with Cases, of Aural and Auditory Vertigo, was read by title, and also referred.

Section VI. Dr. A. Jacobi presented a specimen and read a report of a case of Congenital Atrophy of the Liver, which he considered to be of syphilitic origin.

Dr. Jacobi also reported a case of supra-pubic lithotomy, with the specimen. The operation was followed by peritonitis and abscess, and it was feared that this method of operating was unfitted for such cases.

The sections adjourned *sine die*.

Receptions were given at the residences of Mayor Cooper and Mr. August Belmont, and by Drs. Thomas and Barker at the Academy of Medicine.

FOURTH DAY. FINAL SESSION.

After the presentation of the names of a number of additional members by invitation, a communication was received by Dr. Stillmann, of New Jersey, resigning a patent right to the Association, which was laid upon the table. One from Dr. Frederick Horner, M. D., U. S. N., on the establishment of a committee of benevolence, was also received.

On motion of Dr. Oesterlony, of St. Louis, it was pronounced derogatory to medical editors to have their journals widely and persistently distributed among the laity.

A communication was also read from Dr. Lee, of Philadelphia, recommending searching investigation into the merits of applications for charitable relief at dispensaries.

The treasurer reported receipts amounting to \$5052 during the year, and a balance on hand of \$570.59.

Upon motion the Farmers and Mechanics National Bank of Philadelphia was made the depository of the Association's funds.

Dr. Pratt, of Michigan, offered a resolution instructing the committee of arrangements to present on the first morning of the meeting a complete programme for the business meeting. He also made a motion that the proposed alteration in the code of ethics be made the special order for the second day of the meeting, at 10.30 A. M., and remain the special order until disposed of, which was adopted.

Dr. Keller, of Arkansas, renewed the amendment offered at Atlanta, in regard to choice of officers from the members present.

¹ For details, see page 592 of this number of JOURNAL.

The resolutions offered at the section on State Medicine, last evening, were now brought before the general session and adopted.

On motion of Dr. Marcy, amended by Dr. Pallen, a thousand dollars was appropriated to the permanent secretary for his valuable services.

Dr. Billings's resolution, already mentioned in the report on the section of State Medicine, in regard to the census, was adopted.

The customary vote of thanks was passed, and the president elect, Dr. Holgen, of St. Louis, escorted to the platform amidst much applause.

In the afternoon, by invitation of William Wood & Co., the members of the Association were taken on a delightful trip up the East and North rivers and to Coney Island.

NEW YORK ACADEMY OF MEDICINE.

THE PROPHYLACTIC USE OF COD-LIVER OIL.

At a meeting of the Academy, held May 20th, Dr. Charles H. Alden, of the United States Army, was elected a corresponding Fellow, and Dr. Laurence Johnson presented the report of the delegates of the Academy to the late Decennial Pharmaceutical Convention, at Washington.

Dr. William H. Thomson, professor of materia medica and therapeutics in the medical department of the University of the City of New York, read a suggestive paper on The Prophylactic Use of Cod Liver Oil. After some introductory remarks, he spoke at considerable length of the constitution and character of the red corpuscles of the blood, and claimed that, as they contained twice as much fat as iron, the administration of fat in some form was more strongly indicated in any state of the system where the red globules were diminished than even iron itself; both these substances acting directly as food for these bodies. With our present views in regard to protoplasm, the young blood corpuscle was rightly considered the highest type of life and activity; and it was stated that of all substances with which we are acquainted, fat, which enters so largely into the composition of the blood globule, holds the greatest amount of stored-up energy. A pound of coal, therefore, really gave rise to much more force than a pound of gunpowder; although, on account of the unstable equilibrium of the latter, its action was more concentrated and evanescent. Hence, it could easily be seen what the business was of the fat in the red blood globule. In the embryo was found the greatest proportion of fat, and this substance was needful, not only for growth, but for the work which the tissues perform.

In this connection the writer inquired where in the body was lodged the most fat or oil; and the answer was, In the brain and nervous system. The critical period of life was the five years between the end of lactation and the close of the sixth year. During this period the growth of the brain was incomparably more rapid than that of any other tissue at any time of life whatever, with the exception of the pregnant uterus; so that at the age of seven years it was nearly the size of that of the adult. But not only was the brain increasing in size at this extraordinary rate during this period, the activity of nerve function was also far greater than at any other season of life. Countless new ideas were

daily being grasped, language was acquired, and the factors for the whole future work of life had to be stored away. The physical result of all this brain growth and brain work was that, unless great care was taken with the child, the energies of the rest of the body were sacrificed to the activity of the nervous system; and it was a fact that even under the best conditions the number of red blood corpuscles was maintained at a lower figure at this period than at any other, not even excepting old age. It was, in short, a period of natural anemia; and it was not to be wondered at, therefore, that a very large proportion of children were not able to survive such a critical era. No matter how much the remainder of the system suffered, the brain had to be nourished at all hazards.

Thus, in the affection known as scrofula, the brain was the last part to become diseased. The first tissues to yield were the cartilaginous, and ordinarily the first lesion apparent to the observer was an ulceration of the cornea; so that whenever this made its appearance it was very significant of future trouble. The skin and hair, and not infrequently the joints also, then became affected. Presently the epithelium of the mucous membranes became involved, and then, as a result of this, followed the numerous catarrhs which were so prominent a feature of the affection. The glandular complications of scrofula had frequently been a puzzle to investigators, and much care and ingenuity had been expended in order to account for them satisfactorily; but the writer was of the opinion that the connection between the adenitis and the mucous catarrh was just as simple and direct as that of the bubo with the primary lesion of syphilis.

If these views were correct, cod-liver oil, which by universal experience had been found to be the agent best adapted for conveying fat into the system, was not only the great remedy for scrofula and similar affections when they had once made their appearance, but was also to be regarded as one of the best prophylactics against them. It was unnecessary to claim it as a specific; its action was abundantly explained by the fact that it had the power of artificially relieving the existing anemia, by supplying the needed pabulum directly to the blood globules. We should not, therefore, be content to wait until the corneal ulcer made its appearance before commencing its administration; for the experienced and watchful physician could detect long before this when the brain was growing at the expense of the rest of the body. Whenever this first pronounced evidence of trouble appeared, the system had already become undermined to a considerable extent.

One strong argument in favor of the use of cod-liver oil during the early years of life was the fact that, although, as a rule, it was excessively disagreeable to adults, children had a natural liking for it, and generally took it with great avidity. This seemed to show that there was a necessity for the kind of nutritive material which it supplied; and the writer thought that it should be regarded rather as a food than a medicine, as it commonly is viewed. If this were the case, and it were employed as largely as it should be, he had no doubt that the lives of thousands of children might annually be saved, which are now sacrificed. In many of the families under his care he made use of it in this prophylactic way; giving directions that so long as it was well borne it should be given four times daily during the whole period of early childhood.

MISSOURI STATE MEDICAL ASSOCIATION.

THE Missouri State Medical Association met at Carthage, in the southwestern part of the State, on the 18th of May. The delegation from St. Louis was not large, for the reason that Carthage is about fifteen hours' ride by rail from this city, and because the Illinois State Medical Association was held at the same time at Belleville, only fifteen miles from us, and accordingly took a good many of our physicians from their own association.

Altogether there were about one hundred members present. The officers for the coming year are: President, Dr. Allen, Liberty. Vice-Presidents, Drs. T. U. Flanner, Springfield; T. B. Loyd, —; L. I. Matthews, Carthage; A. B. Sloan, —; and A. W. Smith, —. Recording Secretaries, Drs. A. J. Steele and F. J. Lutz, St. Louis. Corresponding Secretary, H. H. Mudd, M. D., St. Louis.

The programme was as follows:—

Report of a Case of Deformity of the Wrist, by Dr. A. J. Steele, St. Louis.

A paper on the Dangers of Uterine Manipulations and Examinations, by Dr. George Engelmann, St. Louis.

Report of Two Cases of Facial Neuralgia relieved by Operation, by Dr. Halley, Kansas City.

A paper on Lithotomy and Lithopraxy, by Dr. H. H. Mudd, St. Louis. This paper contained the reports of some very interesting experiments concerning the relative danger of cutting and tearing the prostate gland.

A paper on Mind and Matter, by Dr. Allen.

Operations involving the Peritoneum, by Dr. Lutz, St. Louis.

A paper on the Dangers of Sewer Gases, by Dr. Teft, Springfield.

A paper on the Treatment of Conjunctivitis, by Dr. John Green.

Medical Education, by Dr. Laws, Columbia.

A paper on the Progress of Medicine, by Dr. Alleyne, St. Louis, and a paper on the Dry Treatment of Otorrhoea were read by their titles, and referred to the committee on publication.

A very pleasant feature of the meeting was the banquet given on the evening of the 19th, at which the doctors' wives, as well as the doctors, were present. The responses to the toasts were very happy, several of them very witty.

The toasts were as follows: Our Guests, responded to by Colonel Williams, of Carthage. Doctors' Poetry, responded to in verse by Dr. T. U. Flanner, of Springfield. The Southwest, responded to by J. P. Tracy, editor of the principal local paper. The Cross-Roads Doctor, responded to by Dr. Allen, of Liberty. The Specialist, responded to by Dr. Johnson, of Kansas City. The General Practitioner, responded to by Dr. J. Green, of St. Louis. The Ladies, responded to by Dr. G. M. B. Maughis, of St. Louis. On General Principles, responded to by Dr. King, of Sedalia, the wit of the Missouri medical profession. The last toast was of the Medical Press, responded to by Dr. F. J. Lutz, of St. Louis.

Mexico was selected for the next meeting of the association.

The meeting was a very successful one, and was calculated to elevate the character of the profession in that portion of the State, as well as to inspire confidence in the practice of medicine among the people.

Recent Literature.

Aids to Materia Medica and Therapeutics. Part II. (Double Part.) The Vegetable and Animal Substances. By C. E. ARMAND SEMPLE, R. A., M. B. Cantab., M. R. C. P. Lond. New York: G. P. Putnam's Sons. 1880. 32mo, pp. 152.

This little book is an abridgment of the British Pharmacopœia, containing, in addition, some short therapeutic memoranda, and is designed to aid the student "in acquiring some preliminary knowledge of materia medica and therapeutics."

If one may judge from the average quality of those put upon the market, pocket manuals must be the most difficult of all books to prepare. Our author, it seems to us, has not been free from bad judgment and carelessness in the one before us. What advantage, for instance, can be found in mixing the alphabet and natural relations as he has done? The simple alphabet of the Pharmacopœia is certainly convenient, and the natural classification, if correct, is instructive, but this is neither; by taking the classes and subclasses naturally, the orders alphabetically in the classes, and the genera after the same fashion in the orders, he has succeeded in introducing nearly fifty alphabets, and ruining the natural arrangement besides. But when, in addition, ergot is placed among the grasses, pepsine "from the pig" among the ruminantia, and glycerin in "nat. ord. oleacea" (!), we confess ourselves bewildered.

W. P. B.

The Hysterical Element in Orthopaedic Surgery. By NEWTON M. SHAFFER, M. D.

Dr. Shaffer's monograph touches upon a matter of great interest to the profession, and one as yet rather neglected in medical literature. It is perhaps for this reason that in the treatment of many of these cases the quack, with the boldness of ignorance, is much more likely to succeed than the general practitioner, who may be weighted by his knowledge and misled by the simulated symptoms. The subject is one which it is difficult to present to the reader, as the diagnosis in many cases rests upon points which may be clear to the writer, but are not easily formulated for the use of the reader. Dr. Shaffer relates a number of interesting cases where he was able to form a diagnosis, and where the result substantiated the opinion: in a few instances, however, the impression left on the reader's mind is that further facts, or a more detailed report of them, are needed to warrant the recognition of the disease.

Dr. Shaffer justly lays stress on the importance in true joint affections (that is, involving inflammation of the bone) of the symptoms, limitation of the extremes of motion, atrophy, and a diminution of the electrical muscular contractility. These symptoms are wanting in the hysterical joint affections, although some atrophy may occur from bandaging or disuse. The condition of the electrical reaction is a symptom concerning which more clinical investigation is needed before it can be relied upon in a diagnosis by exclusion. Some contradictory evidence has recently been offered,¹ and we believe that the symptom has not yet been studied, in the rare cases mentioned by Volkmann, of inflammation of the epiphysis threatening but not involving the

¹ Berry, New York Medical Record, January 31, 1880.

joint. Although the chances are against encountering such an affection, in recognizing hysteria all possible pathological changes must first be considered.

The book is handsomely published. One mistake justifies a protest. "Diagonized" (page 32) ought not to escape attention. "Diagnose" is bad enough, although unfortunately it is generally used; but "diagonize" is certainly no improvement.

Inflammation of bone is invariably spoken of as "osteitis." Both "osteitis" and "ostitis" are sanctioned in English. The French use the word *osteite*, and the Germans "ostitis." If we write periostitis, why is it not better to adopt the neater word "ostitis"?

The monograph is one which will interest both the general practitioner and the surgeon, and the author deserves thanks for bringing the subject to general attention.

Common Mind Troubles, and the Secret of a Clear Head. By J. MORTIMER GRANVILLE, M. D. Edited, with additions, by an American physician. Philadelphia: D. G. Brinton. 1880. 8vo, pp. 185.

The author of this little book on the lesser forms of mental disturbance was selected by the proprietors of the *Lancet* to make a series of investigations on the management and organization of the English lunatic asylums. His reports to the *Lancet* were subsequently printed in book form, and entitled *The Care and Cure of the Insane*. The present volume is intended as a manual of instruction in mental hygiene. Dr. Granville thinks the will is able to overcome most of the common mental troubles in their early or formative stage. Every alienist knows the importance of stimulating the will in all the stages of mental disease, and habitually practices on this knowledge. It is a necessary and important part of all moral treatment. In the insane the will is often at fault, and, in fact, is usually radically weak by inheritance or constitution, and it is too often defective beyond repair in adult life. No doubt self-training or instruction in self-control at an early age is a great preventive of future insanity in a weak mind. We think Dr. Granville is rather too sanguine of success, even in the lighter shades of mental disorder when developed in the adult. It is very much like lifting one's self by the boot straps for the enfeebled mind to reassume control of its operations by sheer force of will. Diversion, occupation, presentation of new ideas, by means of new surroundings, will often better accomplish the end in view.

We have just seen a young man of thirty suffering from a recurrent attack of mild depression in consequence of his vacillation of purpose in respect to a profession, marriage, and other minor matters. He has some morbid fears in moderation, and is physically in good health and able-bodied. For eighteen months he has striven with all his might, as he says, "to build himself up" mentally, and by subjective processes to regain his self-control, and fit himself to commence a career in life. This effort has been exhausting in the extreme, keeping his attention painfully fixed on his morbid mental operations, and has been without the least degree of success. He was informed that he was beginning at the end of his task. His muscles were under the control of his will if his thoughts were not, and he was directed to engage immediately in

some active business, requiring little brain work at first, but likely to become absorbing and profitable after a time. This advice was followed at once, with prompt relief of depression and a fair prospect of permanent recovery of self-control.

Some of the mind troubles considered by Dr. Granville are defects of memory, confusion of thought, sleeplessness from thought, low spirits, tempers, good and bad. The chapters on mental languor and listlessness and morbid fear are by the unknown American editor, and are among the best in the book. The secret of a clear head is discussed under the titles, Temperature, Habit, Time, Pleasure, Self-Importance, Consistency, and Simplicity. T. W. F.

— Dr. Hans Chiari, prosecutor at the Rudolf's Hospital, Vienna (*Wiener med. Wochenschrift*, No. 44, 1880), has lately met with a case of absence of the parietal pericardium, a rare congenital condition. The subject of it was a man of forty-six, who died from cirrhosis of the liver and tubercular peritonitis secondary to old lung disease. During life the only symptom observed connected with the heart was accentuation of the second sound over the pulmonary artery. At the post mortem, on removing the sternum, the heart was found lying quite free in the left pleural cavity, in immediate contact with the left lung, and apparently in its normal relation to the walls of the thorax. The organ itself, covered by the visceral pericardium, was of normal size, and in all respects healthy. The chief peculiarity observed, apart from the absence of the parietal pericardium, was that the left phrenic nerve lay in front of the heart. In this respect Chiari's case resembles those of Baly (*London Medical Gazette*, July, 1851) and Weissbach (*Wien. med. Wochenschrift*, No. 69, 1868), in both of which the heart also occupied the left pleural cavity. In Chiari's case the upper lobe of both lungs had an accessory lobule. The exact details of the derangement of the mediastina, etc., will be found in the original report. In spite of its rarity, the above condition is not one of great interest, as its presence has never been detected during life. It probably originates before the second month of fetal existence.

— From the *Chicago Medical Gazette* we clip this historical sketch of the total extirpation of the uterus: The first extirpation of the carcinomatous uterus was made by Andreas a Cruce, in 1650. In 1812 Guthrielet operated through the abdominal walls. Langenbeck and Delpech operated by this method, the latter successfully. Langenbeck and Sauter, in 1822, operated through the vagina. Sauter's operation was successful. In 1828 Blondell operated successfully per vaginam. Récamier, in 1829, modified the operation per vaginam by ligature *en masse* of the lower part of the broad ligament by means of a curved needle. Delpech, in 1830, proposed a combination of the vaginal and abdominal extirpation. In 1876 Hennig operated successfully without ligating the broad ligaments. Freund's operation, 1877, described in our issue of March 20, 1880, differs from all previous operations. He was the first to close the wound from the vagina into the abdominal cavity by sutures.

Medical and Surgical Journal.

THURSDAY, JUNE 17, 1880.

A Journal of Medicine, Surgery, and Allied Sciences, published weekly by HOUGHTON, MIFFLIN AND COMPANY, Boston. Price, 15 cents a number: \$5.00 a year, including postage.

All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.

Remittances by mail should be sent by money-order, draft, or registered letter to HOUGHTON, MIFFLIN AND COMPANY, Boston, Mass.

A CONVALESCENT HOSPITAL.

We have received the sixty-sixth annual report of the Massachusetts General Hospital. The pamphlet is a small one, but it contains the brief statement of a change which marks a step forward in the provisions for the charitable care of our sick poor. Through the energy of a Boston lady, Miss Mary Russell, a fund has been started for the construction of a convalescent home, and has reached an amount sufficient to authorize the trustees to begin the erection of a suitable building on their lands at Belmont, a beautiful situation on the hills overlooking the city. To any hospital physician or surgeon the need of such an institution is apparent. A portion of their patients are always in a condition that renders further treatment unnecessary, or which can be benefited only by a change of air. Meanwhile, the patient cannot return to a home which is no shelter for him, provided he be unable to work. Such patients convalesce much more slowly, and occupy space which might otherwise be given to more urgent cases. The average duration of the cure of cases coming to the hospital would by this means be perceptibly shortened, and the efficiency of the charity be correspondingly increased.

It is gratifying to feel that so excellent an institution as this is appreciated, not only at home, but abroad as well. In a recent work entitled *The Pay Hospitals and Paying Wards throughout the World*, by Mr. Henry C. Burdett, one of the highest authorities of Great Britain, we find the following extract, taken from that part of the text which treats of hospitals in this country: "The Massachusetts General Hospital, Boston, will therefore be selected as the representative of the American system: partly, because it is one of the best known and best regulated hospitals in America, and partly on account of the great pains which the authorities, through their representative, Dr. J. H. Whittemore, have taken to supply a full account of the American system of hospital management." A minute description of the methods on which the hospital is conducted follows.

We are glad to be able to record the fact that this hospital bids fair to attain a reputation as a well-administered charity commensurate with the fame it has acquired in the annals of medical science.

— In consequence of the widely-extended prevalence of disease resulting from improper drainage and sewage in the buildings of Princeton College, the students have all been dismissed to their homes until Commencement week.

MEDICAL NOTES.

— We clip the following complimentary notice from the *Boston Daily Advertiser* of Monday last. It is warmly appreciated.

"The Boston Medical and Surgical Journal of June 10th has become a rival of the daily press in so far as it presents a report of the Massachusetts Medical Society's annual meeting, held on the day before. The same number, loyal to the month of learned assemblies, reports the annual meetings of the American Laryngological Association, of the American Medical Association, and of the Connecticut Medical Society. As there is every reason for the prompt reporting of professional meetings, the enterprise of the JOURNAL is quite commendable, and to some extent it is unique, professional papers being usually as slow in reporters' work, which requires promptness, as they have to be cautious and deliberate in the announcement of researches and scientific progress. The same number has interesting articles on heat as an element in fever, and on the transient swelling of lips."

— Having recently received inquiries as to the standing and character of John Buchanan, "M. D.," of Philadelphia, and his medical school, we would say that John Buchanan, alias Rev. James Murray, is a scoundrel. We are happy to add that he is now in jail, and will soon be tried for his fraudulent issue of bogus diplomas, and, we hope, also, for the abortions he has committed. The so-called schools which he has advertised are the Eclectic Medical College, the American University of Philadelphia, Philadelphia University of Medicine and Surgery, Quaker City Business College, Philadelphia Electropathic Institution, and the Livingstone University of Camden, N. J. Every one of these is a fraud and deception, and the diplomas bearing these names are worse than worthless.

The Philadelphia *Daily Record* has unearthed Buchanan, and by its energy, acuteness, and liberality in the use of money has been the happy means of sending this long notorious scamp into confinement. We trust he may meet a punishment which will keep him behind the bars until he is too old to repeat his villainous misdeeds. Those of our readers who wish to obtain a full history of Buchanan's doings will find it in the Philadelphia *Record* of June 10th and 11th, the address of which is Corner Third and Chestnut Streets, Philadelphia.

— A goodly number of the graduates of Harvard Medical School, class of 1878, met at the Revere House on the 8th inst., at 6.30 p. m. After enjoying a social chat, a substantial dinner was partaken of. At a subsequent meeting the following officers were elected for the ensuing year: president, O. F. Ham, M. D.; secretary, H. D. Hicks, M. D.; executive committee, M. H. Prince, M. D.; E. M. Ferris, M. D., P. P. Corney, M. D.

This is the second annual reunion of this class, and it is proposed to perpetuate these social gatherings, and make them the nucleus for the formation of an alumni association for the medical department of Har-

vard University. This is the only class of this school which has attempted anything of the kind, and we wish them every success in their efforts to preserve their class organization.

— *The Medical Record*, in an editorial article on Sins which no Code can Reach, says: "Even the Boston code cannot reach the one who is always ready 'to damn with faint praise' his trusting brother. No set of rules can prevent the so-called successful man from showing his disposition to help a younger brother, especially if the community is told that such help is very necessary. When the old doctor shows a willingness to teach the young and inexperienced practitioner in the presence of the patient there is a generosity about the proceeding which usually appeals to a sympathizing public. If the younger man loses any business by this means the public, although they are sorry for his ill luck, generally think that it is a fortunate circumstance for the patients. At least, there is nothing in the code that prevents such a conclusion. The young man who has no respect for experience, for age, nor for position, is apt to believe that the code, as a whole, only benefits those who dare to transgress its provisions. But there is in reality no law which can punish a practitioner for saying that he has never heard of a worthy brother in his neighborhood; for being surprised that Dr. A. knows anything of chest troubles, that Dr. B. is a gynaecologist, that Dr. C. has much experience in the treatment of children's diseases, or that Dr. D. is anything more than an ordinary man. Although this may only show ignorance of well-known facts in the profession, yet the public generally takes a different view, not always favorable to the unfortunate unknown. When the consulting physician believes, at a critical juncture in the disease, that it is necessary to substitute chalk mixture for bismuth, or to use any other potent remedy instead of the one being employed, it is of course done for the good of the patient, and in strict accordance with such provisions of the code as tend to encourage consultations. Any attending practitioner can at once appreciate the danger of losing the family unless due regard is paid to the suggestions of such a consultant. And so it must be so long as the general profession are governed by the mere letter of the law. The accounts given by Drs. Seabury Jones and A. L. Carroll of professional men who are ready and willing by this and similar means to destroy the good name of an associate find their parallel in the experience of almost every practitioner. It is not that the men who are consulted cannot have a different medical opinion concerning a case, but that they express it either openly or covertly in such a manner as to injure the previous attendant. The shrugging shoulder, the upturned eye, the bland smile, the mild surprise, the ominous and seemingly polite silence, show a respect for the code: at the same time they have a significant effect on the anxious friends of the patient. If the medical attendant is discharged as incompetent, it is of course owing to the ignorance and prejudice of the patient's advisers, rather than to any overt act of the new professional candidate. But when the

practitioner tries to explain to himself why these things should be, neither the old nor the new code helps him a particle. He is more than ever convinced that there are no laws yet enacted that can make a man honest against his will: no loom, however perfect its workmanship, that can convert the auricle of a pig into a purse of silk."

— Says the London *Spectator*, "If parents would only require their girls to take their education leisurely, and not to hurry to the end of it at the same speed as the tougher and less susceptible sex, the habit of intellectual study would improve their health instead of endangering it."

— The following description by Dr. Snowball of the appearances found thirty hours after death in a child five weeks old, brought to the Children's Hospital, Melbourne, with a history of neglect and improper feeding, is given in the *Australian Medical Journal*: "Brain pale, and of such thin consistence that on opening the dura mater it ran out like a pasty fluid. Lungs pale, but healthy. Heart, walls soft and flabby; no blood in cavities. Liver engorged with blood; gall-bladder quite empty; coats thin and pale. Coats of stomach and intestines greatly attenuated and pale; small quantity of feces in lower gut. Kidneys pale, but healthy. All the internal fat absorbed."

— The *Chemist and Druggist* quotes the following from an article by "Ouida" on the Bordeaux Leech Trade: "Certain speculators, we learn, 'have made artificial swamps on the banks of the Garonne, and filled the swamps with leeches. To be profitable, these leeches must multiply themselves by millions; to do this they must be liberally supplied with food; to supply them the Bordeaux speculators buy up all the old and worn-out horses of the province, and drive or drag these horses into the swamps, which are subdivided by wooden compartments, so placed that when these unhappy animals have been forced into the mud there is no escape for them. The leeches fasten on them instantly by thousands; in a few moments the horse is black with crawling creatures; the blood-suckers fix themselves most of all on the open wounds and galls that these poor horses have incurred in their many years of service."

"The frantic terror of the poor horses is described as, bleeding from all their most sensitive parts, they try vainly to shake off the leeches, but are at last sucked down into the noxious slime and seen no more. Nearly twenty thousand horses — aged, infirm, weak from overwork, hunger, and fatigue — are said to be sacrificed annually in this way at Bordeaux. 'Ouida' judges the agonies of the horses will not be a sufficient reason to check the barbarities of greedy speculators, but she hopes that an argument which may be heard is that leeches nourished on agonizing and often diseased horses are very likely to convey ulcers, inflammations, and serofulous maldies into the human system; and she states, on the authority of doctors of eminence, that such diseases do frequently follow the application of leeches."

— Dr. Flexner, of Louisville, receives the thanks

of the *Louisville Medical News* for his solution of salicylic acid, in regard to which Mr. Flexner thus writes: "In the formula which follows advantage has been taken of the solubility of the acid in both glycerine and a neutral salt, thinking that by their combined use the objections to each would be in a measure overcome, since smaller quantities of each were required to obtain the strength of acid that was demanded. The salt chosen is the citrate of potash. It is preferred because of its unobjectionable taste, its ready solubility in glycerine, and its lack of properties that would preclude its use in any case calling for salicylic acid. The formula and its manipulations are as follows:—

℞ Salicylic acid	3i.—Driij.
Citrate of potash	3ij.
Glycerine	3viij.
Simple elixir, q. s. to make	℥i.

The citrate is to be dissolved in the glycerine by the aid of a gentle heat, after which the acid is to be stirred in and a gentle heat maintained until it is completely dissolved. On cooling, simple elixir is to be added to bring it up to the required measurement. The solution is then to be strained; and when prepared with a colorless elixir is of the color of a very pale sherry. It contains five grains of salicylic acid to the fluid drachm, and is miscible in all proportions with water without the separation of any acid.

—We find the following in a recent letter to the *Lancet* on The Scotch Universities and Medical Reform:—

"It is no part of my wish to make invidious comparisons, and I am very far from undervaluing, as all my friends in London and elsewhere know well, the splendid names and labors which have illustrated, and still illustrate, medical science in the metropolis. But the greater the eminence of these individual names, the more it becomes remarkable that a small and thinly peopled country like Scotland, having a scattered population less than that of London alone, not to speak of England, should have been able to maintain in three separate centres of universities medical instruction, a system of elementary biological training on the one hand and of clinical and practical discipline on the other, which have so largely influenced professional thought and medical and surgical practice, even in the metropolis itself. Let any candid and impartial man cast his eye over the list of London celebrities, and ask himself how many of these have owed some part, or the whole, of their medical education to the Scotch universities. May we not fairly argue that a corrupt tree cannot bring forth such good fruits?"

NEW YORK.

—The investigations embodied in the paper on The Criminal Use of Chloroform, read by Dr. J. V. Quimby, of Jersey City, before the section on Medical Jurisprudence and State Medicine of the American Medical Association, would seem definitely to settle a question in regard to which a considerable portion of the profession has hitherto been somewhat in doubt, namely, whether a sleeping individual could be brought

under the anæsthetic effect of chloroform without waking. His attention was directed to this subject, the writer said, by the noted case of the murder of Policeman Richard Smith, of Jersey City. This occurred while Smith and his wife were together in bed, and for this reason the latter was arrested as being *particeps criminis*. She held that she had been chloroformed during sleep, but the State contended that this was impossible, because the fumes of the chloroform would have awakened her from her natural sleep. Here, then, was a nice and very important medico-legal question: If chloroform be properly given, will it awaken a person, or will the person pass from a natural to an artificial or chloroform sleep without being awakened? This was asked of Dr. Quimby at the trial by Mrs. Smith's counsel, and he replied that he had never attempted the administration of chloroform to an individual during natural sleep, and that the books, so far as he knew, were silent on the subject. He then made three experiments with a view of determining this point. He first made arrangements with a gentleman of his acquaintance to enter his room while he was asleep, and give him chloroform by inhalation. This he did with entire success, easily transferring him from natural to artificial sleep without arousing him. He used for the purpose about three drachms of Squibb's chloroform, and occupied seven minutes in the experiment. The second case was that of a boy thirteen years of age, who had refused to take either for a minor operation. By Dr. Quimby's advice his mother gave him a light supper and put him to bed. When he was asleep the doctor administered chloroform and performed the operation without awakening him. The third case was similar, the patient being a boy of ten, who was suffering from an abscess, which it was necessary to open, and the same course was pursued here with equal success. Two inferences might be drawn from these cases, the writer said: (1) minor surgical operations could thus be done with perfect safety, and much more agreeably than in the ordinary way; and (2) an individual somewhat skilled in the use of chloroform might enter a sleeping apartment, and administer chloroform with evil intentions to a person while asleep.

—At the last meeting of the County Medical Society, May 24th, two cases of leprosy were presented, with remarks: the first by Drs. H. G. Piffard and F. R. Sturgis, of New York, and the second by Dr. Samuel Sherwell, of Brooklyn.

—The State Board of Health (the act creating which was at first reported to have been defeated in the legislature, but which was passed before adjournment) met in Albany on the 29th of May for the purpose of organization, and there were present Prof. E. M. Moore, M. D., of Rochester, Prof. Charles F. Chandler, president of the New York city health board, Dr. John S. Delavan, of Albany, the Hon. Erasmus Brooks, of Staten Island, Dr. W. M. Smith, health officer of the port of New York, Dr. James D. Hunt, of the Utica Board of Health, and Dr. Elisha Harris, of New York. Professor Moore was elected pres.

ident, and Dr. Harris secretary of the board, and considerable time was spent in a discussion of the provisions of the law under which the members were appointed. During the meeting each member spoke at length also of the sanitary needs of the various portions of the State, and by this means a useful interchange of sentiment was obtained in regard to this important subject, especially the matter of the registration of births, marriages, and deaths. Two committees were appointed, — one to consider the general sanitary statutes of the State, and the other to propose a series of rules and by-laws for the government of the board, — which were to report at a subsequent meeting, to be held in New York. The central office of the board was established at Albany.

—The new bill to regulate the practice of medicine in the State of New York, which requires all physicians to present their diplomas and register before the first day of October, 1880, also passed the legislature just before the adjournment of that body, and has received the governor's signature.

—During the extremely hot weather of the last week of May the mortality of the city increased very greatly. Between noon of the 27th and noon of the 28th no less than one hundred and twenty-nine deaths were reported to the Bureau of Vital Statistics, which is much the largest death-toll of any day of the present year to date.

—The steamer Gellert, which arrived from Germany a short time since, reported one case of small-pox on board, — that of a child one year old. When seen, the case was believed to be only one of chicken-pox; but by way of precaution Dr. Smith, the health officer, ordered the entire number of immigrants — 1224 — to be vaccinated before they were permitted to land. A day or two after this 3404 immigrants arrived, by four steamers, and of these the Herder, from Hamburg, brought 1035. There being one case of small pox reported, — that of a child who died on the voyage, — all her steerage passengers were also vaccinated.

—Apropos of the subject of vaccination, the first anti-vaccination society in the United States was recently organized in this city, and has just held its second meeting; when "Dr." Robert A. Gunn read a paper entitled, Vaccination a Fallacy and a Crime.

—During the season of last year 1915 children spent a week, and 402 each passed a day, at the summer sea-side home of the Children's Aid Society at Bath, L. I., and the society trusts to be able to accommodate an equal number this year. The home has been in existence now for five years, and during that period has been visited by 10,000 children. The institution was maintained from June 9th to September 15th last year, at an expense of only \$5000.

—A gentleman who was injured in a collision on the New York Elevated Railroad in March of last year, and who sued the company in the supreme court for fifty thousand dollars damages, has had three thousand dollars awarded him. It was claimed that the plaintiff, as the result of the accident, sustained a concussion of the spine, which led to paralysis and a

failure of his mental powers; but several well-known physicians testified during the trial that the patient was really a hypochondriac, the most of his troubles not only not being due to the accident referred to, but existing only in his own imagination.

CHICAGO.

—A concours for the position of clinical adjunct to the chair of diseases of children was held on the 27th ultimo at Rush Medical, Chicago. The contestants were Dr. Ellis, of Galesburg, and Dr. J. Suydam Knox, of Chicago. The latter was chosen.

Miscellany.

A REMARKABLE CASE OF GASTROTOMY.

MR. EDITOR, — An operation of greatest scientific interest and value was recently performed in this city. Dr. H. P. C. Wilson delivered a woman by abdominal section of a living child, the result of an extra-uterine pregnancy, a first child having been born of the same woman three weeks previous and in the natural manner. Drs. Chatard and Wilson are preparing, we understand, elaborate articles on the case; the former giving the history up to the date of operation, the latter from that event on to its termination. These papers will probably appear in the *American Journal of Obstetrics* for July. This case is an exceedingly rare and remarkable one, unlike in many points any that ever transpired either in this country or in Europe. The operation was performed in the presence of Drs. Chatard, senior and junior, A. P. Smith, Wm. T. Howard, McL. Tiffany, Howek, Griffith, and others, invited to witness it. The main facts of the case, kindly furnished at my request by Dr. Wilson, are briefly as follows: Woman aged twenty-two, pregnant for the fourth time with twins. She had three living healthy children. The patient was confined in normal labor on April 15th. From the appearance of the child and statement of the mother it was born one month before its time. The child lived. It was subsequent to this that Dr. Wilson, by physical diagnosis, concluded that there was another child in the abdominal cavity. Exactly three weeks and five days after the birth of the first child, he delivered by abdominal section the second child, a healthy boy, still living at this writing. The operation was gastrotomy in technical distinction from *sectio Casarea*, the incision beginning three inches above the umbilicus. It was performed upon the strict principles of Lister, instruments and ligatures being thoroughly carbolyzed, and the spray used.

The child was contained in a sac filled with about one half gallon of serous fluid, and probably made by the chorion and amnion. The placenta occupied the left half of the brim of the pelvis, and was composed of three distinct and separate formations. The cord divided about two inches before reaching this triple placenta, in order to provide proper vessels for each. It was attached to the left side of the uterus, the left Fallopian tube, and the top of the left broad ligament. The vessels (or smaller cords) leading to the triple placenta were inclosed together under one membrane. The woman lived ninety hours after the operation. There were no symptoms of septicæmia or pyæmia.

Dr. Wilson left her on the morning of her death at seven A. M., her pulse at 130, temperature 101.7° F.; she was cheerful, bright, and asked for a cup of coffee. Ten minutes after Dr. Wilson left she asked the nurse to raise her in the bed, which was done, when, turning very livid, she suddenly and unexpectedly died. Cause of death probably embolism.

Autopsy. No peritonitis; all the abdominal viscera perfectly healthy, and no fluid in the abdominal cavity. This latter fact is easily accounted for, as, during the operation, the sac containing the child had been very accurately stitched to the edges of the abdominal incision (which was made in the median line), so that there was no connection between the sac and the abdominal cavity, and consequently no escape of serous fluids. G. HALSTED BOYLAND, M. A., M. D.

BALTIMORE, May 26, 1880.

DR. WM. WHIPPLE COMSTOCK.

June 1, 1880.

MY DEAR DOCTOR.—I received the inclosed yesterday. I send the remarks I made when seconding the resolutions which were offered at the councilor's meeting in memory of Dr. W. W. Comstock:—

"I am gratified to hear the resolutions which have just been presented; they are deserved.

"Valued as Dr. Comstock was in the community in which he resided, I doubt whether he was well known to the Fellows throughout the State. He was frequently prevented from attending the meetings of the society by professional duties, and when present was a listener rather than a speaker; but I assure you, sir, no man felt a greater interest in the welfare of our society, no man was more tenacious of its honor. From an intimacy, I should say a friendship, of more than forty years I shall ever associate with his memory perfect professional integrity."

Faithfully yours,

D. H. STORER.

DR. WARREN.

The following sketch of Dr. Comstock's life, sent us by Dr. Storer, is from the pen of Mrs. Comstock:—

Dr. Wm. Whipple Comstock, son of Dr. Ezekiel Comstock and Mary Whipple, his wife, daughter of Commodore Abraham Whipple, was born in Smithfield, R. I., March 23, 1800. During his earlier school years he attended Smithfield Academy, and afterwards pursued his studies under the instruction of a private tutor. The time he entered his father's office as a medical student is not now known, as his family of that period are all gone. Between the years of 1820 and 1825 he attended lectures at the medical school then connected with Brown University. Professor Elisha Bartlett, his life-long friend, was with him as fellow-student. During this period his health failed, and he was subject to severe attacks of hæmorrhage of the lungs. For considerable time it was feared that he would never be able to endure the fatigue of the practice of medicine. He married in 1826, went to New Bedford, Mass., to settle, was soon prostrated by sickness, and left in a few weeks. Several years after, the same experiment was made in Boston, with the same result; probably the cause in both places was the sea air. In 1829 he removed to Maine, settled in Buckfield, Oxford County, a mountainous region, with pure, bracing air. After several years' practice there, most of the time driving among the hills, his health being established, he returned to Massachusetts. His

last settlement was in Middleboro, where he practiced nearly twenty-seven years. He died on the 20th of October, 1878.

Perhaps no man ever had more genuine devotion and love at heart for his profession without ostentation or selfishness. No one could feel deeper interest in or stronger desire for the welfare and prosperity of the fraternity. The thorough preparation of young men who were to enter and assume the responsibilities of the profession he ever regarded of the highest importance, and besides his unusually arduous and absorbing duties in his regular practice he was very seldom without students, sometimes a large class, never seeming to feel it a burden to give them his attention. When Dr. Comstock settled permanently in Massachusetts he joined the Medical Society, and has since been one of the councilors.

THE MASSACHUSETTS COLLEGE OF PHARMACY.

THE Massachusetts College of Pharmacy has just issued its fourteenth annual catalogue. The college was instituted in 1823, issued a price book in 1828, and began collecting a library and cabinet of specimens in 1840.

In 1851 the college was thoroughly reorganized; a constitution and by-laws were adopted, an act of incorporation secured, and pharmaceutical meetings inaugurated for the first Monday of each month, devoted especially to scientific purposes.

In the fall of 1854 a course of lectures on pharmaceutical chemistry was delivered by Professor J. P. Cooke, of Harvard University. This course was followed by others, given by Professor Charles Jackson, and by Professors J. P. Cooke and Edward H. Clarke, M. D., of Harvard University; also by the well-known chemist, Charles T. Carney, of Boston.

In the fall of 1867 a class of thirty-five attended a course of lectures given by Messrs. Geo. F. H. Markoe, E. L. Stoddard, and C. M. Tracey. Regular courses of lectures on pharmacy, materia medica, botany, and chemistry have been delivered each succeeding season since then, and the students who have fulfilled the requirements of having attained the age of twenty-one years, of having attended two full courses of lectures in this college, or of one course (the senior) in this after one in some of the other recognized colleges of pharmacy, of having successfully passed all the several examinations, and of having served an apprenticeship of at least four years with qualified pharmacists in dispensing stores have been graduated with the degree of Graduate in Pharmacy, Ph. G.

The college, which has twice suffered injury by fire, is now in a most flourishing condition, and occupies the "old Franklin School Building" on Washington Street, just south of Dover Street, Boston. The rooms are ample for the utmost wants of the college, and comprise a lecture-room, a laboratory, a supply-room, and a library. The lecture-room is large and square, and easily seats a class of one hundred students. It is fitted with complete appliances for demonstration, having a large chemical table, sink, fume closet, chemical apparatus, cabinets, etc. The laboratory is large and well lighted, and is fitted with desks of the most convenient and approved construction, to accommodate two hundred and fifty pupils. It is accessible to both regular and special students. The large and valuable library of S. A. D.

Sheppard, Ph. G., formerly president of the college, has been added to that of the college and alumni association, and the three collections together now form one of the largest pharmaceutical libraries in the United States.

The faculty consists of Geo. F. H. Markoe, Ph. G., Professor of General and Pharmaceutical Chemistry; William P. Bolles, M. D., Professor of Materia Medica and Botany; Edgar L. Patch, Ph. G., Professor of Theory and Practice of Pharmacy; Bennett F. Davenport, A. M., M. D., Adjunct Professor of Practical and Analytical Chemistry, who has in charge the chemical laboratory. The regular term of instruction is for six months each year, and has a junior and senior course with each of the above four professors.

THE ABUSE OF MEDICAL CHARITIES.¹

Drs. M. P. HATFIELD, professor of chemistry, and Roswell Park, demonstrator and assistant to the chair of anatomy, in the Chicago Medical College, have lately published a valuable paper on the abuse of medical charities, from which the following extracts are taken:—

Dispensaries are by no means unmixed blessings, as all of us who have labored in them know. They may be founded never so wisely, may "supply wants long felt," be richly endowed and conscientiously attended by able physicians, and yet become a positive injury to all concerned, unless by hard work and careful watchfulness we can transform our benevolence into true beneficence to the poor.

No one can practice in a large city without being painfully aware that there are hundreds, if not thousands, of sick in great need of properly administered professional attention. These it should be our aim to reach; and were our efforts confined to this class exclusively the fraternity would probably act as a unit in helping along the good work. But when our brethren of the cloth see one patient after another, who used to pay reasonable fees, dropping out of their hands and appealing to dispensaries, where they are received kindly if not cordially, small wonder that they conceive a dislike to the system and its disciples, and refuse to help it or them in any way.

There are enough deserving poor in this city to justify the establishment of at least one dispensary on each side of the river. But there are four "colleges" (to speak courteously of some of them) on the South Side, each with its dispensary, each hard pressed for means to supply medicines, each finding it difficult to secure an adequate professional staff, all vying in their efforts to provide interesting clinics, and, worst of all, one or two making no scruple to pirate upon the practice of outside physicians by offers of gratuitous advice and medicine of their peculiar kind. Out upon such "charity"! Better that any institution, in such need of clinical material that it must thus prostitute itself, were swept into the lake.

But the closest investigation is always needed to prevent injustice to the really deserving and to ferret out the deceivers. Appearances are frequently deceptive; the honest poor will often put on their best

clothes to go to the doctor, while the undeserving as often study an appearance calculated to mislead.

It is not to be expected that the poor laborer can pay the same fee that the well-to-do merchant does. But there can be no doubt that at least half of those who now attend our dispensaries can pay something to the doctor; and there are but few who enjoy such a lucrative practice that they can afford to disregard the aggregate of a number of small fees.

But this is not all. The young physician, who would gladly settle in a large city and enjoy the many benefits it offers, is positively unable to do so unless he has sufficient capital to carry him over a few years of waiting and hard working, and why? Because he sees patient after patient who is able to pay a dollar, or even a half dollar, going by his office to the nearest dispensary, where he is made much of, spoken of as an "interesting case, gentlemen, whom we must watch;" or perhaps an important operation is done gratuitously; and as a fitting climax this young aspirant for medical honor may learn that those whom he had regarded as private patients of his own are advised by some charitably disposed neighbor that there is no use in paying him, because they can go over to such and such dispensaries and be treated for nothing.

No, gentlemen; it is the positive conviction of the great majority of the practitioners of this city that both the profession and the public would be better, much better, off if every dispensary in the city were abolished and the administration of medical charity relegated to individuals instead of to institutions. The deserving poor would be better cared for, while the only sufferers would be the colleges which bid for students by calling attention to the immense amount of clinical material offered for study; and sympathy for these would not be very extended outside their immediate "ring," considering that there are three times as many colleges in existence as there is any call for,—altogether too many young men studying (?) medicine,—and twice as much clinical material as can be advantageously used for any purpose except to make a show.

Another point of some interest. How often is not this question asked of the would-be dispensary patient: "Are you able to pay for treatment?" And the almost invariable answer, usually in characteristic *brogue*, is, "And if I were I wouldn't come here." That is, the very doctor to whom, in their avarice or poverty, they apply is probably the last one to whom they would go if willing or able to pay. And thus the physician who connects himself with a dispensary for the indirect advantage of such a connection deceives himself, and suffers more than he gains.

And just here we may call attention to the fact that the profession is largely to blame in the matter of fees. The popular fee with the average practitioner for an office prescription is one dollar. Now, the question arises, "Is it better to let every patient who is not able to pay this fee slip through our hands and go to a dispensary, or to accept whatever they can pay and keep them from preying upon the profession at large?" A comparative few can afford to sneer at such small fees, but there are well known practitioners in this city who get less than a dollar for an office visit oftener than they get more, and who yet enjoy comparatively lucrative practices. Which is better, for instance; to get five dollars instead of fifty from a poor laborer for curing a stricture, or to treat him at a dispensary for nothing? This disposition to sneer at small fees arises from

¹ The substance of this paper having been presented in various communications to the South Side Dispensary Club, Chicago, the writers were requested to prepare a more formal paper, and bring it to the notice of the profession throughout the country.

mistaken notions, and must react injuriously on all concerned.

The effect of establishing, in a public dispensary, any system of small fees for poor people is certainly demoralizing in the extreme, and in violation of the very idea of a dispensary; it is virtually bidding for practice against outside physicians; while, on the contrary, the effect of what we have just advocated — a system which leads the poor man to seek the doctor's office, feeling that he can pay in proportion to his circumstances — is healthy in the extreme. The doctor's advice is more thought of, and his directions are more implicitly obeyed; while the common people quicker learn the advantage of observing a few simple rules of hygiene, and, thus being induced to take better care of their health, a smaller proportion will be reduced to a condition of absolute and degraded pauperism.

We may be pardoned for alluding, before closing, to one other point, — one which must at the same time be touched upon thoughtfully and yet lightly. It concerns our relations to the clergy in the matter of pecuniary return for services rendered them. We are aware that many a poor clergyman struggles along for a living, his sustenance and support being as hard to gain as that of many a poor physician; but we are also aware that in this city are clergymen with salaries equal to the income of almost any physician here, who would express no small amount of surprise were their family physicians — frequently members of their parishes — to render an account. That is, the doctor is expected not only to contribute to his pastor's support, but never to think of any return for his own services. Why we should be expected to *give* our services to men as well off in worldly goods as we, simply because they care for souls, thus getting no return ourselves for taking care of *their* bodies, is a question which needs not to be prefaced with an apology. How many clergymen with comfortable salaries ever pay their doctor? and how many laymen, on much smaller pay, settle up with a promptness that is refreshing?

[The writers are of the opinion that the pauper sick, like the insane, feeble-minded, blind, aged, and criminal classes, should be attended by physicians who receive salaries from the State. We are informed that the Boston Dispensary has lately adopted the plan of charging a small fee for medicines, which may be remitted at the discretion of the superintendent. — Ed.]

MEDICAL EDUCATION IN THE UNITED STATES.

WE quote the following excellent remarks on medical education from the anniversary address of Dr. D. D. Widama, of Syracuse, president of the New York State Medical Society: —

What shall this better system be? It will not be a system which accepts, without examination, every grist of inferior and worthless grain which may be brought to the factory, drops it into the hopper, subjects it to a rapid and hot grinding process, runs it again through the same mill, set at the same gauge, inspects the delectable product with a mere eye-glance of the ambitious and partial miller, — who owns the mill, — and then sends it into the market neatly branded A No. 1, extra superfine.

It will not be a system which opens its inviting arms, without discrimination, to every applicant for medical honors, whether he be the well-trained and

science-loving student, or an adventurer fresh from the forest, the avil, or the stable, and whose whole literary education consists in a slight, and perhaps contemptuous, acquaintance with the three R's.

It will not be a system which sends such an applicant, or any other, at the very outset of his medical career, to hear lectures on surgery and pathology and therapeutics, when as yet he knows not a single syllable of anatomy, physiology, or materia medica. It will not regard the pupil as a human sausage-skin, to be crammed for four months with intellectual pabulum, which, however much it may distend, can never nourish him.

Its second and final course of lectures will not be a repetition of the first, with the very slightest variations; the same able actors reciting the identical parts which they rehearsed the year before.

And when the term of study is ended this better system will not test the faithfulness and ability and memory of the pupil by its first and only compulsory examination; and this so superficial and farcical as to last, in some departments, not more than ten or even five minutes. And so it will never have to send utterly incompetent and worthless men into the market bearing the brand M. D., and commended by eminent professors to the misplaced confidence of a trusting community.

Already there are cheering indications of healthful progress. Some of the schools of our State have inaugurated, and some have fairly accomplished, changes which seem almost radical. A few demand certain moderate qualifications as prerequisite to admission. A fair proportion have substituted a somewhat easy written for a much easier oral examination at the close of the term. But is it not time that the schools of the Empire State, with their unequaled wealth of clinical material, their teachers of world-wide celebrity and acknowledged preëminence, should heed the reasonable demand of an active, scientific, rapidly advancing age for better methods and more thorough culture? Is it not time that they should answer the unanimous call of the profession to come to the work of elevating the standard of medical instruction, instead of lagging timorously behind, satisfied with tardy half measures, and granting, grudgingly, superficial reforms?

What an impetus would be given to the cause of medical education, everywhere throughout the land, if all the schools in this great State would unite in ordaining: —

(1.) That, for the present, the minimum qualifications for admission shall be equal to those required by the best literary colleges in the Union, and that after four years the possession of the degree of B. A. or B. S. shall be exacted.

(2.) That a complete graded system shall be adopted.

(3.) That the course of instruction shall extend at least three years, of nine months each.

(4.) That constant attendance at lectures and weekly oral and monthly written examinations shall be required of every student.

(5.) That anatomical, chemical, and histological work shall not be optional, but compulsory.

(6.) That satisfactory examinations in each subordinate grade shall precede advancement to a higher grade.

(7.) That the final examination for a degree shall be by an independent board, appointed by the regents of the university.

Would not this be a fair preparation for the better system of education which must bear good fruit; an

education which, in a few years, would elevate the entire mass of the profession; an education which a decent regard for the honor of medical science, for the interests of our successors, and for the welfare of the community imperatively demands? Why should not this or some similar or better plan be adopted? No one ventures to claim that the make-shift system of the past is the fittest for modern times. . . .

Doctors, unlike poets, are not born, but made.

The seventh son has come to be esteemed no less stupid than his six prenatal brothers.

The natural bone-setters are chiefly patronized by the natural fools. Other things being equal, he is rightly considered the best physician who has had the best preliminary training.

And the schools of the future which promptly furnish this training, and cordially meet the highest requirements of an exacting age, are the ones whose diplomas will be sought, because they will be found passports to the favor of an intelligent and discriminating public.

A CASE OF PYELO-NEPHRITIS.

MR. EDITOR,—I have lately attended a fatal case of pyelo-nephritis; and I wish to report it, not because it presents in itself anything new or rare, but rather because it strikingly illustrates the truth of the teaching of our clinical professor at Harvard, that "chronic kidney disease is rarely painful."

D. S., a farmer, sixty-five years old, sent for me May 16, 1880. He complained of pain in the right lumbar region and extending down the course of the ureter, vomiting, anorexia, and restlessness. He had been addicted to the moderate use of alcoholic drinks in early life, but of late had been temperate. The urine was slightly increased in the daily amount excreted, rather high colored, and contained considerable sediment, which settled to the bottom of the vessel in the form of a whitish-gray deposit. A chemical examination showed the solids to be relatively decreased, but actually they were about normal. A microscopic examination of the deposit showed it to be composed of mucus, pus, and a few blood globules. Albumen two per cent. Several subsequent examinations of the urine were made, but the results did not differ materially from the above. The case terminated fatally on Saturday, May 22d.

Autopsy twenty-four hours after death. The permission to make an incision for the purpose of removing the supposed offending kidney was all that could be obtained, and no other organ was seen.

The kidney was enormously enlarged as a whole, forming a fluctuating, irregular tumor, though preserving something of its normal shape. Weight two and three fourths pounds. The perinephritic tissue contained cavities, from which pus oozed on section. The capsule was quite adherent, though in some places scarcely more than the capsule remained. On section it was found to contain one and three quarters pints of pus; also several small calculi, which were polished and hardened, composed, apparently, chiefly of uric acid. There was likewise one large mulberry calculus the size of an English walnut. This over one third of its surface was attached to the pelvis in such a manner as effectually occluded the entrance to the ureter, a process of the stone extending half an inch into the ureter

closely adherent to its inner surface. The glandular tissue was almost entirely destroyed, the calices and pelvis forming one large cavity intersected by fibrous bands. The cortical substance was much atrophied, and in some parts wanting. Apparently, what had once been cortex had in places become inseparably blended with the capsule. The ureter was somewhat shrunken and contained pus, but did not communicate with the pelvis of the kidney.

It must have taken a long time to have brought about the changes described; and yet one week previous to the man's death he was doing full days work at a laborious and exposed occupation, and considered himself exceptionally well for a man of his years.

I have refrained from going minutely into his symptoms, treatment, etc., as these did not differ, probably, from other cases which are of every-day occurrence, and would not therefore be of interest.

O. F. HAM, M. D.

NORTH BARNSTEAD, N. H., May 28, 1880.

A CASE ILLUSTRATIVE OF THE MECHANISM OF AGOPHONY.

In the *Medical Times and Gazette*, May 8th, Dr. Stone reports the following case:—

John M., aged twenty-one, coal-heaver, admitted February 6, 1880, stated that since a fall, three weeks previously, his left side had been tender and painful. Cough of a paroxysmal character soon followed the injury, and great shortness of breath accompanied it, increased by lying on the right side.

On admission, temperature 102.2° F.; pulse 96; respirations 24. Left side of chest dull, motionless. Vocal fremitus absent. Breath-sounds distant and feeble. Distinct agophony over middle of lung posteriorly. Heart displaced to right. He was tapped the same evening, and thirty-six ounces of clear serum drawn off. Resonance returned at once in the upper part of the left side, with vocal fremitus. The case showed no other peculiarities, and recovered quickly.

In commenting on the case, Dr. Stone demonstrated to his class the following facts: (1.) With the ordinary speaking voice, especially on certain words, agophony was distinct; its pitch being an octave or more above the laryngeal note. (2.) With the singing voice, on the note G agophony was totally absent; no sound whatever being transmitted. The same negative result occurred when a vibrating column of air was drawn into the lungs by sucking at a chromatic pitch-pipe. (3.) When the patient was made to whisper, the sibilant sound and all its inflections were completely transmitted to the listener's ear with unchanged pitch. These phenomena were independently substantiated by Dr. Sharkey and other members of the staff. Dr. Stone considered that this case, among many others, confirmed to absolute demonstration his views already expressed as to the causation of this particular auscultatory sign. In the first place, the presence of fluid in the pleura was certain, as a part of it had been extracted. The sequel of the case proved that there was no other morbid condition. Helmholtz had shown that all articulate speech consists of two elements, the laryngeal and oral or buccal. The former is a comparatively slow vibration, with a wave-length of four feet, more or less. The latter consists of numerous high harmonic

or upper partial sounds, superinduced upon the laryngeal ground tone by alterations in the resonant cavity of the mouth; these harmonies differ for each vowel, and in some cases, such as the English sounds for A, E, and I, are considerably higher in pitch than the foundation sound. These are just those on which agrophony is loudest. The whispering voice is formed of oral vocalizations alone, with a mere laryngeal hissing, and no musical note whatever. In his opinion, the layer of pleural fluid, which was well known to stop slow vibrations sensible to tactile sense, and termed vocal fremitus, also filtered off, as it were, the coarse waves of the laryngeal note, while it let pass the finer undulations of the affiliated harmonies. The note of the pitch-pipe was also entirely stopped, whereas the whisper was entirely transmitted. The action of the muting sheet of liquid is an exact physical parallel to that of a transparent glass in front of a fire, which stops the bulk of the coarser heat vibrations, while it allows the more delicate undulations of light to pass with but little diminution. Acting on this analytical view, he had followed Helmholtz in attempting to reproduce agrophony synthetically under purely physical conditions. In this he had fortunately succeeded, and had shown the observation before the Royal College of Physicians. A bladder containing water was placed over a fenestrated india-rubber tube approximately the size of the larger bronchi and trachea. On making a distant assistant speak, sing, and blow a pitch-pipe into the tube, and applying the ear, aided by means of a stethoscope, to the upper surface of the water in the bladder, an exact reproduction of the phenomena named above was obtained.

MALFORMATION OF LEFT AURICLE.

MR. EDITOR.—I think the following history may prove useful to those interested in the study of the diseases of childhood: J. E. W., aged seven years, always supposed by his parents to have been a healthy boy. For two weeks after birth was cyanosed. Never had any of the fevers or acute diseases of children. Never had a diarrhoea, or even vomited, till just before death.

At three years of age he often said he was sick, on getting up mornings, but as soon as he ate or drank something he felt well.

He always looked pale, yet his lips were of very good color. Exercise, instead of flushing his face, would cause a deadly pallor. Would often be found with head and shoulders off the bed, so that the thorax was lower than the abdomen. He generally assumed this position about two A. M. Never was troubled with short breathing, but often swallowed as if something were rising in the throat.

Had no cough. Countenance pleasant, perhaps a little anxious. Would often complain of feeling bad, and at such times either food or drink would relieve him; after three years of age, this was a constant symptom till time of death.

March 15, 1880, he took a slight "cold;" coughed very little.

March 16th. Complained of pain over platysma myoides and sterno-cleido-mastoid muscles of right side of neck; otherwise, felt about as well as usual.

March 17th. Felt well, appetite poor, pale ring

around the lips. Abdomen rather tumid. Rested badly on night of 17th, talked in his sleep, and had all symptoms of worms.

March 18th. Was up and dressed; wished to walk out. At eight A. M., I gave one fluid drachm of Squibb's fluid extract spigelia and senna. About an hour after taking the spigelia and senna, he had a watery passage from the bowels. Patient died suddenly at ten A. M.

Autopsy thirty-six hours after death. Condition of body, well nourished; considerable serous fluid oozed from adipose tissue on section of abdomen. Lungs partially collapsed: left lung small, two lobes; right lung large, and contained four lobes; small portion of lower lobe of right lung oedematous, and united to mediastinum from diaphragm to clavicle.

Heart: pericardium contained about an ounce of serous fluid, and was attached to diaphragm in a circular form for at least two and one fourth inches in diameter; the pericardium forming a part of the diaphragm at this point. Above, it was attached to the left lung by broad aponeurotic bands. Mediastinum thickened with a fibrous tissue. Right auricle full of fluid blood. Right ventricle flabby and thin, about one line in thickness.

Left auricle rudimentary, holding not over a fluid drachm, and had more the appearance of being an enlarged pulmonary vein than an auricle, the cavity just admitting the handle of an ordinary scalpel for three fourths of an inch; the four pulmonary veins uniting like the branching of an artery or vein.

The left ventricle was full of fluid blood, and contained a few small shreds of fibrin. Walls of left ventricle hypertrophied, being five eighths of an inch thick.

Liver, broad, thick, and short, with four instead of five lobes, wholly on right side, with an adherent band, commencing at vertebral column and running along the diaphragm at the junction of the diaphragm muscle with the aponeurotic structure of the same, and ending at sternum, forming a band of horse-shoe shape. This band was thick, holding the liver against the diaphragm. Others extended to stomach, where pericardium, diaphragm, liver and stomach were all united and bound together.

Yours very truly,

PAUL ROACH.

QUAKER STREET, NEW YORK.

THE POSTURE OF WOMEN DURING LABOR.

MR. EDITOR.—I should be greatly indebted to you if you could assist me in obtaining some information with regard to a subject in which I am now interested,—the posture of women in labor.

In civilized communities of the present day, women are delivered in their beds, mostly on the back, sometimes on the side. Other methods, and especially the obstetrical chair, have been done away with long ago; but not so a rather peculiar custom, which antedates the obstetrical chair,—the delivery of a woman while seated on the lap of an attendant.

This was the practice among various nations a thousand and more years ago, and is still customary in some portions of Mexico, of Peru and Chili, in the interior of Wales, and in the early part of this century it was a favorite method of delivery in parts of West Virginia.

Other equally peculiar postures are in other countries assumed by women during labor, and I am anxious to collect all possible information which I can obtain with regard to the method of delivery, especially the posture occupied during labor, among all such people as are not yet governed by the modern laws of obstetrics, — our present Indians, the natives of South America and Africa, and the people living in mountain districts in the interior of those portions of the Old World which are not as yet attacked by all the accomplishments of modern civilization.

A circular letter asking such information will soon be sent out to the medical officers of the army by the Bureau of Ethnology of the Smithsonian Institution, but I have no doubt that among your readers, also, there are many who have observed curious positions occupied by women in labor. I would be thankful to these if they would place me in possession of such facts as have come to their notice.

Trusting that you may give me some assistance in this matter, I am yours, etc.,

GEO. J. ENGELMANN, M. D.

3003 LOCUST STREET, ST. LOUIS, May 4, 1880.

LUNACY SUPERVISION.

MR. EDITOR. — In your journal of May 20th was an editorial entitled The State Board of Health, Lunacy, and Charity Tub and the Whales, which, instead of dealing in argument, was devoted to "throwing mud." The "lunacy reformers" are unjustly attacked. Will you permit us to state our position? We strenuously objected to the creation of the clumsily organized Board of Health, Lunacy, and Charity, for we believe that under this arrangement no one department has its just share of attention. But, sirs, the "asylum ring" have, to the surprise of European and American psychiatrists, philanthropists, and true statesmen, defeated us at every turn in our efforts for an effective "lunacy commission," and by this consolidated board alone could supervision of our "close asylums" (a phrase of Dr. Samuel G. Howe) be "smuggled in." We urged Governor Long, before his inaugural, to recommend the separation into three boards.

Two new appointments are about to be made on the board. The following petition was gotten up by the "young woman" so unnecessarily attacked in your journal: —

"To his Excellency, Hon. John D. Long, Governor, and the Honorable Council: The success of the experiment tried in New York, in the appointment of Mrs. Josephine Shaw Lowell on the State Board of Charities, has induced the governor and senate of that State, also, to appoint Miss Sarah M. Carpenter on the same board.

"The undersigned citizens of Massachusetts would respectfully urge the governor and council to appoint on the Board of Health, Lunacy, and Charity, to fill one of the vacancies which occur this year, some one of the many women of which this State is justly proud, who are interested in our state charities, and have the requisite ability, industry, and opportunity.

"We would further urge upon your Excellency and the Honorable Council the importance of appointing persons upon this board who have no official connection with or personal interest in any of the state institutions."

We simply ask, you see, for a female appointment (which the JOURNAL indorses), and that a *rital principle* of civil service reform be recognized in these appointments. We challenge the name of any reader of the JOURNAL who objects to, or indeed does not cordially approve, this last clause of the petition, which alone has aroused the venomous malice of those who are desperately working to defeat honest central supervision of our asylums.

This, then, is "the head and front of our offending." No personalities, no personal complaints, no original theories advanced.

For the dignity of their profession, in the name of enlightened medical science, the medical men of Massachusetts must take a more active interest in the "problems of insanity," insisting upon admittance as consulting physicians into insane as into other hospitals, and not give this great subject entirely over into autocratic hands, some of whom, with amazing audacity, defiance, and relentlessness, attack every honest, even the moderate reformer, who, without personalities, works for efficient central lunacy supervision, hoping thereby to secure an honest, pure, economic, scientific, and humane asylum system, which shall no longer be criticised abroad by such men as Bucknill, Mandslley, Von den Steinen, and many others.

VASELINE OINTMENTS.

MR. EDITOR. — I see that in your number of the JOURNAL for May 27th reference is made to the use of "some soft paraffin" base in the preparation of ointments. Vaseline has, I know, been used for that purpose. Now this preparation has also been used by some dentists in cases of exposed pulp, and for this very reason, that it would not change, and afforded a mild and non-irritant dressing. Within a short time, however, at least two lots of it have been found to become rancid, and to develop a fungus upon its surface. This would seem to call for caution in the use of this and similar preparations, and to take manufacturers' assertions with at least one grain of salt.

THOS. H. CHANDLER.

IN REGARD TO FEES.

MR. EDITOR. — In an article in your issue of last week you say that I, among other physicians, testified that "five dollars was the usual and fair charge for a professional visit." On the contrary, while stating that in many exceptional cases, namely, for a first visit, for casual visits to strangers at hotels, for visits at unusual hours, for visits to the distant outskirts of the city, say at Roxbury, Charlestown, East and South Boston, and for surgical visits, in which a dressing was implied, I thought that a reasonable, proper charge, I distinctly said that, "so far as I knew, the fee of three dollars was that more generally charged than any other," and that I also understood that to be the minimum charge named in the fee-table for visits-in-ordinary, that is, in a continuous attendance."

As I understand the rules of the Boston Medical Association, as fortified by long-established custom, physicians are expected, in making out their bills, to apprise their patients of the full value of their services, in accordance therewith; while, at the same time, they

are also equally enjoined to remit any part of the amount which the circumstances of the patient may require.

Therefore, there would seem to be no reason for such departures from the minimum charges of the fee-table as are sometimes made, even when the circumstances of the patient do not justify them; although, if a physician choose, on the face of his account, to notify his patient that he considers his professional services worth less than the *standard value*, he is, under the laws of Massachusetts, at perfect liberty to do so.

HENRY G. CLARK.

NEAR-SIGHT IN THE YOUNG.

MR. EDITOR. — In an article On the Prevention of Near-Sight in the Young, by Hasket Derby, M. D., published in your issue of June 3, 1880, I find the following assertion, namely, "that near-sight is seldom, if ever, congenital." Dr. Edward T. Ely, in his *Ophthalmoscopic Observations upon the Refraction of the Eyes of Newly-Born Children* (*Archives of Ophthalmology*, vol. ix. No. 1), tells us that he examined one hundred and fifty-four eyes, under atropia, of infants, of whom only six were over two months old, and found no less than *eighteen per cent.* of them myopic, or near-sighted.

I have seen children before or at the very commencement of their school-days with a very considerable degree of near-sightedness. The truth seems to be that myopia is *not very rarely* congenital, but more frequently acquired, either as the result of hereditary tendency, of over-use or abuse of the eyes, or from defective "tissue building" and the effects of hygienic circumstances, even where the use of the visual organs has not been immoderate.

I fully agree with Dr. Derby that "near-sight may begin with spasm of the accommodation," but I would venture to suggest that the case he adduces in evidence is inconclusive. He says that at his last examination "the ophthalmoscope showed" the myopia to be "real, and not due to spasm;" but it does not appear that the eyes were examined under atropia. Dr. Agnew and myself have frequently together seen cases which seemed to be myopic when subjected to ophthalmoscopic examination, in which, however, hypermetropia was found to exist, in marked degree, after the accommodation had been suppressed by the full use of atropia. The ophthalmoscope *alone* cannot be depended upon in the class of cases to which the doctor's case clearly belongs, nor can a correct diagnosis be made in them without atropine. Respectfully yours,

DAVID WEBSTER.

MEDICINE MEN IN COUNCIL.

THE following is an editorial from the *New York Herald* of June 3d: —

About fifteen hundred doctors are assembled in this city as a sort of professional congress, for precisely what important purpose the congress itself would, perhaps, be troubled to tell. But it is an age when the gregarious instinct of humanity makes itself felt on the lines of some common pursuit or taste, and lawyers, bankers, railroad men, peace societies, and parsons get together for an annual powwow, and why not the

doctors? There are some reasons, perhaps, why the doctors should not be counted in such a category. In the first place, while all these practitioners from the rural districts are away from home a great many people will take advantage of the opportunity to get well of their innumerable maladies, and the doctors will be great losers thereby. But a more substantial reason is that the doctors, as men trained in more severely rational methods of thought, should not follow the example of mere anniversary makers, who come out once a year to air their vocabularies; nor yet the example of railroad men and bankers, who get together to consult how they may more effectively prey upon the public. As the doctor's impulse in life is not primarily toward the accumulation of wealth, and is certainly toward the exposure and correction of vain theory, he cannot be part of an annual congress for either of the reasons that commonly contribute to the making of such rookeries, and the wonder is why he takes part at all in a vain show. There are points of view, however, from which this gathering of medical men may be instructive to the people, if not useful to the doctors. From what other pursuit of great importance to the people could there be gathered together from all parts of a country like ours a representation of fifteen hundred men so largely endowed with sound culture and rare intelligence, and so little endowed with that wealth which is popularly regarded as the substantial fruit of all labor? Rich doctors are rarities, — though we presume that nearly all doctors who deserve to succeed make money enough to live comfortably. But a rich man is not a rarity in any other pursuit that requires as much knowledge or as high an order of intelligence as is required to make a good doctor. On the contrary, in all pursuits that require that intelligence, and in many that require far less, everybody gets rich, in this country certainly. But this is the most striking phenomenon presented by this profession: that it is a body of men of far higher than ordinary intelligence, men of great culture and industry, who labor incessantly from boyhood to old age, and, taking life genially and easily, are contented with an infinitely less substantial reward than is necessary to satisfy any other class of men. It is as if a medical education lifted a man into serenely regions of life than those in which is waged the savage daily strife for lucre, and if it has that effect in fact it would be a good thing if medicine could be studied a great deal more than it is.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U. S. ARMY, FROM JUNE 5, 1880, TO JUNE 11, 1880.

BARTHOLOMEW, J. H., captain and assistant surgeon. Relieved from duty in Department of California and assigned to duty in Department of the Columbia. S. O. 123, A. G. O., June 4, 1880.

KEEL, W., first lieutenant and assistant surgeon. Granted leave of absence for one month, with permission to apply for an extension of two months. S. O. 124, A. G. O., June 5, 1880.

GRAY, WILLIAM W., first lieutenant and assistant surgeon. Relieved from duty at Fort Point, Cal., and to return to his proper station, Vancouver Barracks, W. T., by steamer on 31st inst. S. O. 75, Division of the Pacific and Department of California, May 26, 1880.

BOSTON SOCIETY FOR MEDICAL OBSERVATION. — A regular meeting will be held Monday next, at eight o'clock, at the hall of the Medical Library Association. Reader, Dr. C. F. Folsom. Subject, The Pathology of Insanity. After this meeting the society will adjourn to the first Monday in October.

A. T. CABOT, Secretary.

Lectures.

SOME OF THE SYMPTOMS OF BRIGHT'S DISEASE.

BY ROBERT EDIS, M. D.,
One of the Visiting Physicians at the Boston City Hospital.

IN this hospital, as you know, we have a special service to which are assigned, on entering, most of the patients supposed to be affected with renal diseases, as well as with those of the nervous system. Hence a hasty diagnosis, sufficient for the proper location of the patient, is made by the admitting physician, and it is interesting to group together some of the cases presenting important symptoms, which have been made the basis of this diagnosis, and see where they lead us pathologically. It is very apt to happen that if a patient enters with a pain not obviously referable to some of his thoracic or abdominal viscera he is called "nervous," and sent to us; while our "renal" cases are those whose legs are swelled. In a large proportion of cases this assignment is correct. It is worth while to note, in this connection, upon how trivial a basis a diagnosis of "Bright's disease" is frequently set up, to the great glory of quacks and mineral waters. A man whom I know very well came to me the other day and asked if he had "kidney disease." He had been to get a new pair of spectacles, and the optician, failing to suit him, inquired if he had pain in his back. He said "Yes," and was then informed that the reason he could not see was because he had "kidney disease," of which, however, no indication was to be found either in urine or retina. The disappearance of a sediment of urates, which may be due simply to greater dilution of the urine, to the subsidence of a slight febrile attack, or even to the chamber-pot being transferred to a warmer room, has been adduced as evidence of the great efficacy of a quack medicine in the cure of "kidney complaint."

The method of distribution practiced here leads us to consider the meaning of the symptom *dropsy*; that is, the collection of fluid, independently of inflammation, in the serous cavities, the subcutaneous and submucous cellular tissue, and the tissue of the skin itself. The fluid consists chiefly of water, with the salts of the blood, more or less albumen, and a small amount of urea. More albumen is usually found in pleural and peritoneal dropsy than in the subcutaneous fluid. (Analyses given in Hoppe-Seyler.) There are probably three conditions which give rise to dropsy, either of which may act alone, but of which in most cases two at least act together.

The first of these is venous obstruction. Although it has been denied that this alone could give rise to extravasation of fluid, because no œdema has been found to follow the ligation of certain veins, it appears that if the ligatures are applied in such a way as to *cut off the lateral circulation*, the œdema of the district drained by the obstructed vessels takes place without any further interference. Clinically this is best seen in phlebitis, especially the "milk leg," or phlegma-ia alba dolens, of puerperal women, where the œdema may be strictly confined to the limb whose vein, from the extension of some puerperal inflammation, is plugged, and can be felt hard and painful at the groin, affecting the other only when, as very frequently happens, the phlebitis also crosses over. Again, in valvular disease of the heart, where the venous circulation is impeded, we may have

extreme dropsy; and no other form yields more readily to a treatment which invigorates the heart and enables it to pump off the back water. In cirrhosis of the liver, where the flow of blood in the portal vein, which drains so large a part of the abdominal viscera, is impeded, we have the effusion chiefly in the abdominal cavity, the legs being perhaps but little affected. Ovarian disease excluded, the tense round belly, supported on or attached to a pair of shriveled legs, with, it may be, a little swelling about the ankles, goes a long way toward the diagnosis of hepatic cirrhosis without further question.

The second factor of dropsy, or, perhaps, I should say, of anasarca, since it is of comparatively little consequence in the pleura and peritoneum, is the dilatation of the smaller vessels from vaso-motor paralysis. The importance of this condition in some cases was shown by Ruyvier, who found that ligation of the vena cava in a dog produced no œdema of the hind legs until one sciatic nerve, containing the vaso-motor filaments, was cut. Then œdema appeared on the corresponding side. The discrepancy between these experiments and those just quoted, which show that ligation alone is sufficient to produce œdema, is to be explained simply by the establishment of a collateral circulation; so that a degree of obstruction which in itself is insufficient to produce œdema may do so when dilatation of the peripheral vessels takes place from vaso-motor paralysis. The existence of this condition alone is not so easy to determine clinically. Usually all that we see from vascular dilatation is congestion and redness; but I think that some cases of rapid anasarca, or partial œdema, without discoverable lesion of the veins or blood, are most easily accounted for in this way; and even in acute renal dropsy, where the condition of the blood is probably the overruling factor, yet the sudden appearance of the swelling certainly suggests an additional cause.

A wheal of urticaria, or the rapid swelling which accompanies poisoning from ivy or dogwood, probably illustrates this pathological condition on a small scale. I have seen a sudden œdema of the face, distorting it beyond recognition, come on in a few hours, and go off in a few more, without any previous or subsequent discoverable sickness. A few weeks ago a young lady had a very sudden attack of dyspnoea, and felt as if "filling up," her voice husky, and complexion, when I saw her, of a vivid scarlet, having previously been purple. Her face was swollen, and the eyelids (especially prone, from the laxness of the tissue, to œdema) puff. Upon the action of an emetic the redness disappeared almost immediately, and the commencing œdema soon followed. It seemed to me that this was only an extreme and unusually acute form of that erythema or urticaria which, in some persons, follows the use of special articles of diet, notably fish, if not quite fresh. Erythema, by the way, even painful, and almost simulating some more permanent lesion of the skin, is not an uncommon accompaniment of œdema, as some of you saw in the case of a man in Ward F (McK.), who soon after died with very large white kidneys.

The lax pale œdema in the paralyzed hand of a feeble hemiplegic may properly be classed here. Probably both of these causes (the first and second) may be grouped together as sluggish and impeded peripheral circulation. Certain it is that increased arterial pressure has nothing to do with the exudation of serum from the vessels. In that form of Bright's disease (the

contracting kidney) where the blood tension is high, we usually have comparatively little dropsy until late in the disease, when the pressure is diminishing from failure of the heart. In those cases where dropsy is a prominent symptom, we are likely to find a feeble heart; so that while the *veins* are full, the blood passing back to the heart with difficulty, stagnating in the capillaries, and there getting rid of a portion of its fluid, the *ris a tergo* on the arterial side is not only not above but below the normal degree.

The third cause is a watery condition of the blood, hydraemia, with a diminution of solid constituents, resulting either, as has been assumed, from a drain of albumen from the blood, or a failure on the part of the kidneys to withdraw water. Mere anæmia, in the sense of loss of the red corpuscles, has comparatively slight effect in this direction, although when extreme we find it accompanied by dropsical effusions in dependent parts of the body. The first of these conditions, that is, the drain of the albumen, can hardly be the efficient one in those cases where general anasarca makes its appearance early, before time enough has elapsed for any considerable quantity of albumen to be lost. In very chronic cases, however, this drain, while sometimes insignificant, as in the contracting kidney, in others, as when there is parenchymatous inflammation, is of great importance. A case in which fifteen hundred c.c. of urine should be passed daily, holding two per cent. of dry albumen, would be an extreme one, to be sure, but one which probably occurs not very infrequently. This would give thirty grams of albumen withdrawn from the blood every day. An egg, calculated according to the data of Payen, contains about seven and a half grams of dried albumen: so that unless both appetite and digestion continued to be vigorous the loss would be enough to make itself decidedly felt in the production of hydraemia. "The blood is very thin, often almost like meat water, pale, and forms on coagulation a very loose gelatinous clot." (Lehmann.)

The mere accumulation of water, or rather of a weak solution of urinary salts, from a failure of the kidneys to get rid of it, is a condition which may be and is developed with rapidity, and is undoubtedly a chief factor in the production of sudden and rapid anasarca; although, as I have already said, I think we may have also at work the second cause of anasarca, that is, the paralysis of the vessels of the skin and subcutaneous tissue, allowing stasis and transudation. The frequent origin of cases of acute renal dropsy in exposure to cold seems to me to implicate the skin as well as the kidneys. Swollen legs, then, may have very various origins, and we must exclude first those of purely local significance. Even periostitis, rheumatism, and varicose veins, as well as phlebitis, may lead to mistakes. The dropsy of pure anæmia might deceive us, but I think the error is more likely to be in the other direction, of considering œdema as dependent upon anæmia, which is really connected with a more serious condition.

We might say somewhat the same of phthisis; for, although dropsy may supervene upon the hydraemia of phthisis, especially toward the last, the cause of it is by no means infrequently to be found in actual renal disease, the parenchymatous form being the more usual, not rarely accompanied by more or less amyloid change of the arterioles. Such a case was William C—, whom some of you saw, and who suffered much from dropsy and dyspnoea before his death. His physical signs of phthisis were well treated, and his urine

contained considerable albumen and a great variety of casts. His kidneys were large, smooth, and very fatty. Also Sarah M—, in G 28, had a cough for three or four years, about which she had comparatively little to say, but complained of the swelling of her feet and legs, which began three months before entrance. One morning she told me she feared she should have a "broken breast," it was so hard and swollen. The right mamma was simply œdematous, because she had lain upon that side, the fluid gravitating to the most dependent part. Later the whole side became dropsical. Her urine contained three quarters per cent. albumen and numerous casts, leading to a diagnosis of parenchymatous nephritis, which was confirmed by a post-mortem examination of the kidneys. They weighed, together, about five hundred grams, or fifteen and a half ounces, and showed both parenchymatous inflammation and amyloid degeneration of the arteries.

Another case, not altogether similar, you may see in John T. (F 27), who came in chiefly on account of swelling of the legs. The first examination of his urine showed nothing abnormal. Other symptoms led us to examine his thorax, and we found the signs of chronic consolidation at the upper part of the left lung. The swelling has entirely gone, and he has improved considerably in other ways, especially in regard to his night sweats, which yielded to atropia; but he is still in bed, and the destruction of the left lung is progressing. A second examination of his urine discovered a trace of albumen and a few hyaline casts. Does this mean interstitial nephritis, or merely an impeded circulation in the kidney? We have hardly data enough to be quite certain, but I think the latter, chiefly because the urine has a higher specific gravity than would be likely to come into interstitial nephritis (1018).

Among our cases of dropsy we not infrequently find one of cardiac origin, which is not always to be separated off-hand from the renal; for while in cardiac dropsy we meet with albumen and casts, in renal dropsy we may have enlargement of the heart and dyspnoea. Beside this, the presence of both forms of disease in the same person is by no means a rare occurrence. The distinction, however, can usually be made, partly by the presence or absence of other symptoms, but frequently also by the urine alone. In cardiac dropsy, we have a small amount of albumen and a few hyaline casts, which you will say, perhaps, point equally to interstitial nephritis. In the latter affection, however, they are found in a copious, light-colored urine of low specific gravity, while in that from the congested cardiac kidney we find, besides, much coloring matter and a high specific gravity. The urine is also passed in small amount, its increase corresponding with increased vigor of the heart and diminution of the dropsy, so that its quantity furnishes, as Jaccoud points out, a very good practical guide in the administration of digitalis. If, on the other hand, the enlargement and violent impulse of the heart, in a case of contracting kidney, are liable to lead us astray, the absence of souffles (though this is not invariable), the hard and (usually) regular pulse, the pale, light urine, should show us that the cardiac lesion is only a part of the general disease which is most strongly developed in the kidney.

You have seen too many cases of cardiac dropsy for me to delay long upon this point, but one case, which occurred recently in our wards, and which some of you

saw in Ward J 10, is interesting enough, for several reasons, to be remarked upon :

William M—, a short, stout man of about fifty, had a chill, followed by high-colored urine, shortness of breath, pain in the left side, and swelling of the feet and legs. When he entered he was purple, with his abdomen and legs swollen. His heart's dullness was enlarged, the action very irregular and feeble, and there was a systolic murmur at the apex. It was impossible at this time to get a sphygmographic tracing of his pulse. His urine was of sp. gr. 1016, with a trace of albumen and a few leucocytes and hyaline casts.

Under the use of cathartics and digitalis he improved very much : his complexion became natural, the dropsy diminished, and the heart's action grew much stronger, as shown by the successive tracings of the sphygmograph, but it was always very irregular, much of the time giving many contractions, audible at the thorax, but not perceptible at the wrist. The improvement was, however, only temporary, for he died after two or three weeks, quite suddenly.

The abdomen, pleuræ, and pericardium all contained an excess of serum, and there was a pericarditis especially at the upper part, between the aorta and pulmonary artery. The valves were normal, and there was no decided hypertrophy. The kidneys were simply firm, hard, and congested (cyanotic).

I must confess to some surprise at this result, for the systolic apex soufle, the irregularity of the heart's action, and especially the failure of so many pulse waves to reach the wrist, had led me to believe in the existence of a mitral lesion.¹

The only explanation of the symptoms which I can offer is one the correctness of which it would be very difficult to prove, in the absence of such an examination as is seldom made at an ordinary autopsy. The pericardial fibrinous exudation was almost entirely in the immediate neighborhood of the great cardiac plexuses of nerves, and it seems to me far from improbable that the excitation or compression of these nerves by the inflammatory products may have been sufficient to give rise not only to the irregularity of rhythm, but to imperfect closure of the mitral valve. Oppolzer considered the irritation of the neighboring nerves as one of the causes of many symptoms in pericarditis, even where the exudation is small.

Finally, we have many cases of true renal dropsy, which, however, vary considerably among themselves as to the amount and the location of the effusion ; and this variation is not a merely accidental one, but marks out (not always, to be sure, with absolute accuracy) the division of so-called Bright's disease into two important groups : that is, in parenchymatous nephritis, the large white or mottled kidney, we are likely to have considerable and tolerably persistent dropsy ; in pure interstitial nephritis, the small atrophied kidney, we may have none at all, or very little. As to the location of the effused fluid, we find here, as in cardiac disease, that it is chiefly influenced by position, although some other circumstances seem to have a greater weight in renal than in cardiac dropsy. Thus the face and eyelids may be the earliest affected. (Edema of the larynx and glottis, as a consequence of general disease, and not of any local irritation, is very rare, so that Bartel says he has never had a case. One such case occurred in our

wards two years ago, where the swelling began in the feet, but afterward occupied all the tissues immediately beneath the lower jaw, including larynx and glottis, the limbs, body, and face being free. The oedema was sufficient to affect the voice, but became a source of actual dyspnoea only at the very last.
